THE ENCYCLOPÆDIA BRITANNICA

FOURTEENTH EDITION

VOLUME 21

SORDELLO TO TEXTILE PRINTING

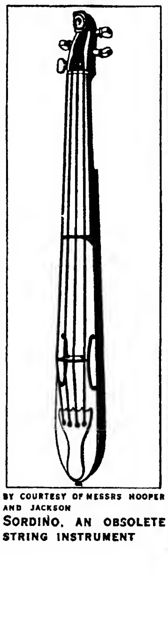
SORDELLO, a 13th-century Italian troubadour, born at Mantua, who is praised by Dante in the *De vulgari eloquio,* and in the *Purgatorio* is made the type of patriotic pride He is the hero of a well-known poem by Robert Browning The real Sordello was the most famous of the Italian troubadours. About 1220 he appeared at Florence in a tavern brawl; and in 1226, while at the court of Richard of Bonifazio at Verona, he abducted his master's wife, Cunizza, at the instigation of her brother, Ezzelino da Romano The scandal resulted in his flight (1229) to Provence, where he seems to have been for some time. He entered the service of Charles of Anjou, and probably accompanied him (1265) on his Naples expedition, in 1266 he was a prisoner in Naples The last documentary mention of him is in 1269, and he is supposed to have died in Provence. His didactic poem, *L'Ensenhamen d'onor,* and his love songs and satirical pieces have little in common with Dante's presentation, but the invective against negligent princes which Dante puts into his mouth in the 7th canto of the *Purgatorio* is more adequately paralleled in his *Serventese* (1237) on the death of his patron Blacatz, where he invites all Christian princes to feed on the heart of the hero

For Sordello's life and works *see* the edition of Cesare de Lollis (Halle, 1896)

SORDINO, SORDONI, SORDUN, musical terms somewhat promiscuously applied (1) to contrivances for damping or muting wind, string and percussion instruments (*Sordini*); (2) to a family of obsolete wind instruments blown by means of a double reed (*Sordoni* or *Sordun*); (3) to a stringed instrument To these must also be added the *Surdellina* or *Sordellina,* a kind of musette invented (*see* BAGPIPE) in Naples in the 17th century.



BY COURTESY OF MESSRS HOOPER AND JACKSON

SORDINO. AN OBSOLETE STRING INSTRUMENT

SOREL, AGNES (*c.* 1422–1450), mistress of King Charles VII. of France, was born of a family of the lesser nobility at Fromenteau in Touraine. She was attached to the service of Isabel of Lorraine, queen of Sicily, wife of René of Anjou, the brother-in-law of Charles VII From 1444 until her death in 1450 she was the acknowledged mistress of the king, the first woman to hold that semi-official position which was to be of such great importance in the subsequent history of the old régime Her ascendancy dated from the festivals at Nancy in 1444, the first brilliant court of Charles VII. Her sudden death from dysentery, shortly after the birth of her fourth child in 1450, was attributed, apparently without foundation, to poison

See A Vallet de Viriville's articles in *Bibliothèque de l'École des chartes* (3rd series, tom. 1), and R Duquesne, *Vie et aventures galantes de la belle Sorel* (1909).

SOREL, ALBERT (1842–1906), French historian, was born at Honfleur on Aug 13, 1842. He was of a characteristically Norman type, and remained all his life a lover of his native province and its glories He studied law in Paris, and after a prolonged stay in Germany entered the foreign office (1866) In 1870 he was chosen as secretary by M. de Chaudordy, who had been sent to Tours as a delegate in charge of the diplomatic side of the problem of national defence; in these affairs he proved himself a most valuable collaborator. After the war of 1870–71, when Boutmy founded the *École libre des sciences politiques,* Sorel was appointed to teach diplomatic history (1872), a post in which he achieved great success. Some of his courses have formed books: *Le Traité de Paris du 20 novembre 1815* (1873); *Histoire diplomatique de la guerre franco-allemande* (1875), also the *Précis du droit des gens* which he published (1877) in collaboration with his colleague Théodore Funck-Brentano. In 1875 Sorel left the foreign office and became general secretary to the newly-created office of the *Présidence du sénat*

His duties left him sufficient leisure for the great work of his life, *L'Europe et la révolution française* (8 vols, 1885–1904). His object was to do over again the work already done by Sybel, but from a less restricted point of view and with a clearer and more calm understanding of the chess-board of Europe He spent almost 30 years in the preparation of this history; the analysis of the documents, mostly unpublished, on French diplomacy during the first years of the Revolution, which he published in the *Revue historique* (vol v.–vii, xi.–xiii), shows with what scrupulous care he read the innumerable despatches which passed under his notice.

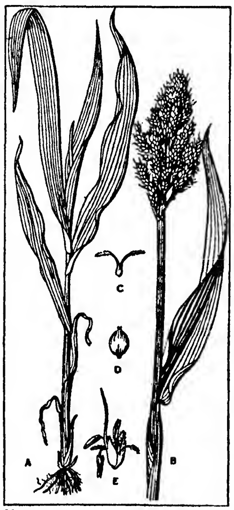
He was also, and above all things, an artist. He drew men from the point of view of a psychologist as much as of a historian. Sorel was elected a member of the Académie des sciences morales et politiques (Dec. 18, 1889) and of the Académie française (1894). He died in Paris on June 29, 1906.

Sorel's other works include: *La Question d'Orient au XVIII[e] siècle, les origines de la triple alliance* (1878); *Montesquieu* (1887); and *Mme. de Staël* (1891) in the *Grands écrivains* series; *Bonaparte et Hoche en 1797* (1896); and *Recueil des instructions données aux ambassadeurs* vol. i. only (1884). Most of his essays and articles contributed to various reviews and to the *Temps* have been collected into volumes: *Essais d'histoire et de critique* (1883); *Lectures historiques* (1894); *Nouveaux essais d'histoire et de critique* (1898); *Études de littérature et d'histoire* (1901).

SOREL, CHARLES, Sieur de Souvigny (1597–1674), French novelist, was born in Paris about 1597. In 1635 he was historiographer of France. He tried to supersede the pastoral romance by the novel of adventure, the *Histoire comique de Francion* (1622). He also wrote *Le Berger extravagant* (1627), *Polyandre* (1648) and *La Connaissance des bons livres* (1673). He died on March 8, 1674.

SOREL, a town of Quebec, Canada, at the confluence of the Richelieu and St. Lawrence rivers. Pop. (1921) 8,174. It occupies the site of a fort built in 1665 by A. de Tracy to guard the route by way of the Richelieu to Lake Champlain and the Hudson, and is named after the first commandant.

SORGHUM, a term applied to a number of varieties of a small cereal grown extensively in warm countries, and known botanically as *S. vulgare, Andropogon Sorghum,* or *Holcus Sorghum.* It includes one of the most important tropical grains, great millet, Indian millet, or Guinea corn. In India it is known as *jawari* (Hindustani), *jowari* (Bengali), *cholum* (Tamil), and *jonna* (Telugu) and in the West Indies as Negro or Guinea corn. It is a strong grass, growing to a height of from 4 to 8 or even 16 ft.; the leaves are sheathing, solitary, and about 2 in. broad and 2½ ft. in length; the panicles are contracted and dense, and the grains, which are enclosed in husks and protected by awns, are round, hard, smooth, shining, brownish-red, and somewhat larger than mustard seeds. The plant is cultivated in Asia, in the United States, and in the south of Europe. E. Hackel (in *Die natürlichen Pflanzenfamilien*) says the culture probably had its origin in Africa, where a variety known as durra has become the most important cereal; the natives also chew the stem, which contains sugar. The sweet sorghums are grown in China, north India, Africa and America for the manufacture of syrup and for forage.



MILLET OR GUINEA CORN (SORGHUM VULGARE)
(A) Shoot, (B) Flowering stem (inflorescence), (C) Pistil, (D) Fruit, (E) Single flower, (C & E) Enlarged

A full account of the cultivation and use of the species in India will be found in Sir G. Watt's *Dictionary of the Economic Products of India* (1893). *See* also W. W. Robbins, *Botany of Crop Plants* (Philadelphia, 1924).

SORIA, a province of Spain, formed in 1833 out of Old Castile. Pop. (1920) 151,595; area, 3,983 sq.m. Soria is a bleak and lofty region, bounded on three sides by mountains. A range of sierras culminating in the peaks of Urbion (7,389 ft.) and Cebollera (7,139 ft.) on the north, and the great Sierra del Moncayo (7,707 ft.) on the east, separate the valley of the Duero from the Ebro. Almost the whole of the province belongs to the region watered by the Duero and its affluents. There are extensive forests of pine, oak and beech and large tracts of pasture land. The climate is cold and dry, and the scenery grand, but austere. Between 1887 and 1900 the population decreased by nearly 7,000; it is now stationary.

SORIA, the capital of the Spanish province of Soria; on the river Duero (Douro). Pop. (1920) 7,619. The churches of Santo Domingo and San Nicolas, the collegiate church of San Pedro, the cloisters of the convent of San Juan, and several other ecclesiastical buildings are fine specimens of Romanesque work of the 12th and 13th centuries. Near the Duero are the ruins of the old citadel, and the 13th century walls may still be seen.

SORITES, in logic, means a series of connected syllogisms, in which the conclusion of one syllogism is used, as a premise in another. *See* Logic, and the bibliography given there.

SORMOVO, a town of Russia, in the Nizhegorod province, on the Volga. It was a village of about 6,000 inhabitants in 1897, but has grown since the provision of electric power to a population (1926) of 40,071. It manufactures machinery and refines crude Baku naphtha brought up the Volga river.

SOROCA, a frontier town of Bessarabia, Rumania, capital of the department of Soroca, situated on the right bank of the Dniester, 81 m. north-north-west of Kishinev. Pop. (1928) 27,000 including many Jews. Corn, wool, fruit, wine and cattle are exported. Soroca was the old Genoese colony of Olchiona, and still has the ruins of a 13th century Genoese castle. The Moldavians erected a fortress in the 15th century. Soroca changed hands many times between Poland, Russia and Turkey.

SOROLLA Y BASTIDA, JOAQUIN (1863–1923), Spanish painter, was born in Valencia, and received his art education first in his native town and under F. Pradilla, and then in Italy and Paris. His first striking success he achieved with "Another Margaret," which was awarded a gold medal in Madrid and was bought for the St. Louis Gallery. He soon became the acknowledged head of the modern Spanish school of painting.

His "Fishermen's Return" was acquired for the Luxembourg Museum. His exhibit at the Paris Universal Exposition of 1900 won him a medal of honour and his nomination as Knight of the Legion of Honour. Between 1910 and 1920 he contributed to the Hispanic Society of America, a series of portraits of Spanish writers and a "Panorama of the Forty-nine Provinces of Spain," consisting of 49 compositions with views and costumes. He died at Madrid on Aug. 10, 1923. He is represented at the Berlin National Gallery, at the Venice and Madrid Museums and in Buenos Aires.

See Hispanic Society of America, Eight Essays on *Joaquin Sorolla y Bastida* (1909); A. de Beruete y Moret, *Sorolla y Bastida,* 1920.

SORORATE. This term was introduced by Sir James Frazer to designate all marriages with a wife's sister, whether in the lifetime of the first wife or after her death. In his view it is complementary to the custom of the levirate and both "are offshoots from one common root, a system of group marriage in which all the husbands were brothers and all the wives were sisters to each other, though not to their husbands; and that system in its turn originated in a simple desire to get wives as easily and cheaply as possible." (*Folklore of the Old Testament*, vol. ii., p. 317.)

It is to be noted that in cases where fraternal polyandry is permitted, the wife of the eldest brother is the common wife while the wife of the youngest brother belongs to him alone, and that in societies where a definite relation as the cross-cousin, is prescribed for the eldest son, the youngest son is free to marry whom he will or can, within the more general rules of exogamy, so that the wives of the younger brothers in such cases do not or may not possess the status required for the wife of the eldest brother, while the younger sister of the late wife would possess that status. In the case of the matrilineal Garos, marriage with a prescribed relative, the cross-cousin, the son of the woman's mother's brother, is binding only on the youngest daughter. No rights are conferred by marriage with the elder daughters. It is further to be noted that as with the Ba-Ila (*The Ila speaking peoples*, vol. i., p. 391) a woman though married may be called to leave her husband and her children to become the wife of her late sister's husband under the sororate regulation. In India it is generally the wife's younger sister

who is taken as a second wife when the first wife is barren or suffers from an incurable disease In advanced communities marriage with the deceased wife's sister occurs for practical reasons when there are young children to be brought up. In primitive communities the relationship created by the first marriage between the two families is marked by a series of obligations of an economic, religious and social nature so that there is clearly an advantage in maintaining the existing mode of relationship over the creation of a new series of analogous obligations Thus in Ashanti "in the case of chiefs when a wife dies, the wife's family are expected to replace the deceased woman by giving her sister in marriage to the chief" (R. S. Rattray, *Ashanti*, p. 34, 1923). In the case of societies organized on the dual basis (*see* DUAL ORGANIZATION), each moiety acts as a reservoir of spouses for the other moiety and is obliged to find mates.

See Frazer, *Folklore of the Old Testament*, vol ii (1918); Westermarck, *History of Human Marriage*, vol iii. (1921).

SORORITIES, organizations of women distinctive to colleges and universities in the United States. Sororities are self-perpetuating, secret in nature chiefly as to initiation ritual, having each a characteristic badge, and various symbolic insignia—colours, flower, tree, flag, patron, motto and pledge pin. The first Greek letter sorority, Kappa Alpha Theta, was founded at De Pauw university in Jan 1870. In 1928, it contained 1,037 chapters and about 175,000 members.

Government and Activities.—The governments of all are similar—a council of three to nine members to carry out legislation enacted at national or district conventions. Many sororities have accumulated endowment funds Practically all sororities publish quarterly magazines, song books, catalogues and bulletins of various kinds. Because of inadequate living conditions in many institutions, each sorority has sanctioned the establishment of lodges by its chapters. Fifty per cent of the chapters are so equipped, this property being worth about $5,000,000 A large Panhellenic hotel has been built in New York city The National Panhellenic Congress was formed in Chicago in 1902. Sororities have made valuable surveys of collegiate conditions as they pertain to women and have done much to improve them. Extraneous philanthropic work has been undertaken, and many sororities assist their members with scholarships, loan funds, vocational and employment bureaux

See William Raimond Baird, *Manual of Fraternities* (1927); Ida S. Martin, *The Sorority Handbook* (10th ed., 1928). (R. L. F.)

SORREL (*Rumex acetosa*) (family Polygonaceae), a hardy perennial, native to Great Britain and found throughout the north temperate zone The leaves are used in soups, salads and sauces Sorrel grows freely in any good garden soil, and is increased by dividing the roots during the early part of spring. They should be planted in rows 15 to 18 in apart. The leaves, when fully grown, are gathered singly The common garden sorrel is much superior to the wild plant; French sorrel (*Rumex scutatus*) is a hardy perennial, distributed through Europe but not native in Great Britain

SORRENTO, a city of Campania, Italy (anc. *Surrentum*, *q.v*) Pop. (1921), 7,121 (town), 9,783 (commune). It stands on cliffs about 160 ft high, between the Bay of Naples and the Bay of Salerno. It is a summer and winter resort, its northerly aspect rendering it comparatively cool At Sorrento Bernardo Tasso wrote his *Amadigi;* and Torquato Tasso, to whom a marble statue has been erected in the Piazza, was born in the town in 1544.

SORSOGON, a municipality (with administration centre and 47 *barrios* or districts), capital and port of the province of Sorsogon, Luzon, Philippine Islands, on the Gulf of Sorsogon, 279 m. from Manila. Pop. (1918), 16,694. It lies in a rich agricultural region, abacá being its chief product; and is a busy commercial place. The language is Bikol.

SOSIGENES, Greek astronomer and mathematician, probably of Alexandria, flourished in the 1st century B C. According to Pliny (*Nat. Hist* xviii. 25), he was employed by Julius Caesar in the reform of the Roman calendar (46 B.C.), and wrote three treatises. From another passage of Pliny (ii. 8) it is inferred that Sosigenes maintained the doctrine of the motion of Mercury round the sun, which is referred to by Cicero, and was also held by the Egyptians. He was the tutor of Alexander of Aphrodisias, the most famous of the commentators on Aristotle. He wrote a work on *Revolving Spheres,* from which some important extracts are preserved in Simplicius's commentary on Aristotle's *De caelo*

SOSITHEUS (*c* 280 B C), Greek tragic poet, of Alexandria Troas, a member of the Alexandrian "pleiad" He must have resided at some time in Athens, since Diogenes Laërtius tells us (vii. 5, 4) that he attacked the Stoic Cleanthes on the stage, and was hissed off by the audience. Suidas calls him a Syracusan According to an epigram of Dioscorides in the Greek Anthology (*Anth. Pal.* vii. 707) he restored the satyric drama in its original form. Part of his pastoral play, *Daphnis* or *Lityerses* is extant

See O Crusius *s v.* Lityerses in Roscher's *Lexikon der griechischen und romischen Mythologie.* The fragment in Nauck's *Tragicorum graecorum fragmenta* apparently contains the beginning of the drama

SOSNOWIEC, a town of Poland, in the province of Kielce Pop. (1921) 86,700. It owes its rapid rise to its position in the centre of the Dambrowa coalfield, between Bendzin, Dambrowa and Katowice. The towns of this region are almost continuous, extending from Kielce into the provinces of Cracow and Silesia Sosnowiec is also a great railway junction Situated on the Warsaw-Vienna railway, it is a junction for the Kielce and Radom, Cracow and Lemberg, and Katowice and Breslau lines. Electric power stations have been established, sending a cable as far as Czenstochowa, while an electric tram system is being extended to the other towns in the basin. Iron foundries and some textile factories, as well as coal mines, employ large numbers of workmen Sosnowiec is, after Lodz, the largest Polish industrial town.

SOSTENUTO, musical term signifying that the passage so marked is to be played in a "sustained" manner.

SOTADES, Greek satirist, of Maronea in Thrace (or of Crete), chief representative of the writers of coarse satirical poems, called κίναιδοι, composed in the Ionic dialect and in a metre named after him "sotadic" He lived in Alexandria during the reign of Ptolemy II Philadelphus (285–247 B C.). Sotades was imprisoned for a satire on Ptolemy, escaped to Caunus, was captured, shut up in a leaden chest and thrown into the sea

Only a few genuine fragments of Sotades have been preserved (*see* J. G. Hermann, *Elementa doctrinae metricae*, 1816).

SOTER, pope from about 167 to 174 He wrote to the Church of Corinth and sent it aid. His letter is mentioned in the reply given by Dionysius, bishop of Corinth, and Harnack thinks it can be identified with the second so-called epistle of Clement.

SOTHERN, EDWARD ASKEW (1826–1881), English actor, was born in Liverpool on April 1, 1826, the son of a merchant. After acting in the English provinces, he went to the United States in 1852 There he made a great success in New York in 1858 as Lord Dundreary in Tom Taylor's *Our American Cousin.* He gradually worked up the humour of this part so that it became the heart of the play He created the title rôle in T. W Robertson's *David Garrick* (1864). Sothern also made a hit as Sam Slingsby in Oxenford's *Brother Sam* (1865). Sothern was a born comedian, and off the stage had a passion for practical joking He died in London Jan. 21, 1881

SOTHERN, EDWARD HUGH (1859–), American actor, was born at New Orleans on Dec. 6, 1859, the son of Edward Askew Sothern, noted English comedian. His first stage appearance was in a small part with his father's company at the Park theatre in New York city in 1879. He toured England in 1882–83, became leading comedian in McCullough's company in 1883, and under Daniel Frohman was leading man at the Lyceum theatre in New York city. He married Virginia Harned in 1896, and in 1899 formed his own company with her as his leading lady

In 1900 he appeared in the title rôle of *Hamlet*, in 1901 in that of *Richard Lovelace* and in 1902–03 as Villon in *If I Were King,* three of his greatest rôles In 1904 he entered into combination with Julia Marlowe, the two first appearing together in *Romeo and Juliet* at Chicago. Except for two years, 1907–09, they played together almost continuously until their retirement from the stage They were married in 1911. Besides *Romeo and Juliet* they have co-operated in *Much Ado About Nothing, Taming*

of the Shrew, Merchant of Venice, Twelfth Night, Macbeth, Jeanne D'Arc, John the Baptist, When Knighthood was in Flower and *The Sunken Bell.* Although noted chiefly as a Shakespearian actor, Sothern has a repertory of over 125 diverse parts.

See his autobiography, *The Melancholy Tale of Me* (1916); and W. M. Winter, "The Art of E. H. Sothern," *Century Magazine* (May, 1915).

SOTHIC PERIOD, in ancient Egyptian chronology, the period in which the year of 365 days circled in succession through all the seasons. The tropical year, determined as it was in Egypt by the heliacal rising of Sirius (Sothis), was almost exactly the Julian year of precisely 365¼ days (differing from the true solar year, which was 11 minutes less than this). The sothic period was thus 1,461 years. (*See* EGYPT: *Ancient.*)

SOTHO, a powerful nation of Bantu-speaking peoples, numbering some 500,000, which inhabits the Crown colony of Basutoland in South Africa. It is made up of a large number of different tribes, which were welded together early last century by the great chief Moshesh. Culturally they belong to the central division of southern Bantu (*see* SOUTH AFRICA: *Ethnology*).

See E. Casalis, *The Basutos* (1861); E. A. T. Dutton, *The Basuto of Basutoland* (1923).

SOTO, FERDINANDO [Fernando, or Hernando] **DE** (1496?–1542), Spanish captain and explorer, born at Jeréz de los Caballeros, in Estremadura. In 1519 he accompanied d'Avila on his second expedition to Darien. In 1528 he explored the coast of Guatemala and Yucatan, and in 1532 he led 300 volunteers to reinforce Pizarro in Peru. He played a prominent part in the conquest of the Inca kingdom (helping to seize and guard Atahualpa, discovering a pass through the mountains to Cuzco, etc.), and returned to Spain with a fortune of 180,000 ducats, which enabled him to marry the daughter of his old patron d'Avila. Excited by reports as to the wealth of Florida (a term then commonly used in a much wider extension than subsequently), he sold part of his property, gathered a force of 620 foot and 123 horse, armed four ships, and obtained from Charles V. a commission as "adelantado of the Lands of Florida" and governor of Cuba. Sailing from San Lucar in 1538, he first went to Havana, his advanced base of operations; starting thence on May 12, 1539 he landed in the same month in Espiritu Santo bay, on the west coast of the present State of Florida. For nearly four years he searched for gold. He probably passed north into Georgia as far as 35′ N., then south to the neighbourhood of Mobile, and finally north-west towards the Mississippi, which was reached in 1541; the following winter was spent on the Ouachita, in modern Arkansas and Louisiana, west of the Mississippi. As they were returning in 1542 along the Mississippi, De Soto died. De Soto's men, under Luís Moscoso de Alvarado, descended the Mississippi to the sea in 19 days from a point close to the junction of the Arkansas with the great river, and thence coasted along the Gulf of Mexico to Panuco.

Three narratives of this expedition are extant, of seemingly independent origin. (1) *Relacam* . . . (Evora 1557) professing to be the work of a Portuguese of Elvas, who had accompanied the expedition, was published in an English translation by Hakluyt in 1609 (reprinted from the 1611 edition by the Hakluyt Society [London, 1851]). (2) The famous history of Florida by Garcilasso de la Vega; it was completed in 1591, and first appeared at Lisbon in 1605 under the title of *La Florida del Ynca,* and has since passed through many editions in various languages. (3) A report presented to Charles V. of Spain in his Council of the Indies in 1544, by Luis Hernandez de Biedma; it is printed in Ternaux-Compans' "Recueil de pièces sur la Floride" in the *Historical Collections of Louisiana* (Philadelphia, 1850) and in W. B. Rye's reprint for the Hakluyt Society of Hakluyt's translation of the Portuguese narrative (*The Discovery and Conquest of Terra Florida,* London, 1851).

SOTTO VOCE (It.), lit. "under the voice," that is, an undertone. Term applied both to music and speech.

SOUBISE, BENJAMIN DE ROHAN, DUC DE (?1589–1642), Huguenot leader, younger brother of Henri de Rohan, inherited his title through his mother Catherine de Parthenay. He served his apprenticeship as a soldier under Prince Maurice of Orange-Nassau in the Low Countries. In the religious wars from 1621 onwards his elder brother chiefly commanded on land and in the south, Soubise in the west and along the sea-coast. Soubise's chief exploit was a singularly bold and well-conducted attack (in 1625) on the Royalist fleet in the river Blavet (which included the cutting of a boom in the face of superior numbers) and the occupation of Oléron. He commanded at Rochelle during the famous siege. When surrender became inevitable he fled to England, which he had previously visited in quest of succour. He died in 1642 in London.

SOUBISE, CHARLES DE ROHAN (1715–1787), peer and marshal of France, the grandson of the princesse de Soubise known to history as one of the mistresses of Louis XIV. He accompanied Louis XV. in the campaign of 1744–48. Soon after the beginning of the Seven Years' War, through the influence of Mme. de Pompadour, he was put in command of a corps of 24,000 men, and was defeated at Rossbach (1757). He continued in the service until the peace of 1763. He died in Paris on July 4, 1787.

SOUHAM, JOSEPH, COUNT (1760–1837), French soldier, was born at Lubersac on April 30, 1760, and became a general of division in 1793. He was disgraced with Moreau and Pichegru for alleged participation in the conspiracy of Cadoudal. He regained his rank in 1809, took a notable part in Gouvion St. Cyr's operations in Catalonia, and won the title of count. In 1812 Masséna, in declining the command of Marmont's army recommended Souham for the post. The latter was thus pitted against Wellington, and by his skilful manoeuvres regained the ground lost at Salamanca. At the fall of the First Empire he deserted the emperor, and was well received by Louis XVIII., who gave him high commands. He retired in 1832, and died on April 28, 1837.

SOULT, NICOLAS JEAN DE DIEU, Duke of Dalmatia (1769–1851), marshal of France, was born at Saint-Amans-la-Bastide (now in department of the Tarn) on March 29, 1769, the son of a notary. He was intended for the bar, but on his father's death in 1785 he enlisted as a private in the French infantry, and rose rapidly in the army. He laid the foundations of his military fame by his conduct in Masséna's great Swiss campaign (1799), and especially at the battle of Zürich. He acted as Masséna's principal lieutenant through the protracted siege of Genoa, and after many successful actions he was wounded and taken prisoner at Monte Cretto on April 13, 1800. The victory of Marengo restoring his freedom, he received the command of the southern part of the kingdom of Naples, and in 1802 he was appointed one of the four generals commanding the consular guard. Despising Napoleon, Soult affected devotion, being appointed in 1803 to the command at Boulogne and in 1804 to be one of the first marshals of France. He commanded a corps at Ulm, and at Austerlitz (*q.v.*) he led the decisive attack. After the peace of Tilsit he was created (1808) duke of Dalmatia. In the following year he was given a command in Spain after the battle of Gamonal and he pursued Sir John Moore to Corunna.

For the next four years Soult remained in Spain, and his military history is that of the Peninsular War (*q.v.*). In 1812 he was obliged, after Wellington's victory of Salamanca, to evacuate Andalusia, and was soon after recalled from Spain at the request of Joseph Bonaparte, with whom he had always disagreed. In March 1813 he assumed the command of the IV. corps of the *Grande Armée,* but he was soon sent to the south of France to repair the damage done by the defeat of Vittoria. His campaign there is the finest proof of his genius as a general, although he was repeatedly defeated by Wellington, for his soldiers were raw conscripts, facing Wellington's veterans.

Marshal Soult's political career was less creditable, and it has been said of him that he had character only in front of the enemy. After the first abdication of Napoleon he declared himself a Royalist, received the order of St. Louis, and acted as minister for war (Dec. 3, 1814–March 11, 1815). When Napoleon returned from Elba Soult declared himself a Bonapartist, was

made a peer of France and acted as major-general (chief of staff) to the emperor in the Waterloo campaign.

At the Second Restoration he was exiled, but was recalled in 1819 and in 1820 again made a marshal of France and in 1827 a peer. After the revolution of 1830 he made out that he was a partisan of Louis Philippe, who revived for him the title of marshal-general. He was minister for war, 1830–34 and 1840–44, and ambassador extraordinary to London for the coronation of Queen Victoria in 1838. In 1848, when Louis Philippe was overthrown, Soult again declared himself a republican He died at his castle of Soultberg, near his birthplace, on Nov 26, 1851. Soult published a memoir justifying his adhesion to Napoleon during the Hundred Days, and his notes and journals were arranged by his son Napoleon Hector (1801–1857), who published the first part (*Mémoires du maréchal-général Soult*) in 1854 Le Noble's *Mémoires sur les opérations des Français en Galicie* are supposed to have been written from Soult papers

See A Sallé, *Vie politique du maréchal Soult* (1834), A de Grozelier, *Le Maréchal Soult* (Castres, 1851); A. Combes, *Histoire anecdotique du maréchal Soult* (Castres, 1869).

SOUND. The definition of the word sound depends upon the point of view adopted. Subjectively it may be regarded as the sense impression of the organ of hearing; objectively, the vibratory motion which produces the sensation. The physiological and psychical aspects of sound are treated in the article on HEARING. In what follows we shall deal mainly with the physical aspects of sound, that is, with the phenomena which occur outside the ear. Just as it is customary to regard "light" as including invisible radiations in the ultra-violet and infra-red, so we shall regard sound as including mechanical vibrations of all frequencies audible or otherwise. It may, in fact, be regarded as a branch of mechanics which deals with alternating or vibratory motion. As we shall see, the study of alternating mechanical motions is closely analogous to that of alternating electrical currents, the mathematical theory of one is often of much assistance in the consideration of the other. Alternating currents provide also a convenient means of exciting the corresponding mechanical vibrations, of whatever frequency. Recent developments in the production of alternating currents of very high frequency have their counterpart in the production of corresponding mechanical vibrations.

Sound Due to Vibratory Motion.—It is common observation that all sounding bodies are in a state of vibration. In the more obvious cases (*e.g.*, a vibrating stretched string) the vibrations can be seen directly as a blurred outline, or optical magnification may be necessary to reveal their existence. The vibrations of a body which is emitting sound can sometimes be felt if the finger touches the surface lightly; any appreciable pressure by the finger is often sufficient to stop the sound and the vibration instantly. The simple experiment with a lightly suspended pithball brought into contact with the surface of the body emitting sound, proves in a convincing manner that the body is in vibration—a resonant glass or metal vessel, or a tuning fork, serve excellently as a source of sound for this experiment.

Medium Necessary for Sound Transmission.—When a body, *e.g.*, a tuning fork, vibrates in an elastic medium such as air, the latter is compressed and rarefied by the "to and fro" motions of the vibrating body. These compressions and rarefactions are passed on from one layer of the medium to the next and in this manner the vibrations of the body are transmitted through the medium to a distant point. The necessity for an elastic medium to transmit the sound from the source is best illustrated by an experiment first performed effectively by Boyle and later by Hawksbee (1705). In this experiment a bell is suspended by a silk thread inside a glass globe connected to a vacuum pump. When the globe is full of air and the bell is excited, the sound can be heard clearly. As the air is withdrawn by the pump, however, the sound weakens and ultimately, when the vacuum is very good, the bell becomes inaudible. The experiment is more effective when an electric bell is set ringing continuously in an atmosphere of hydrogen reduced to an extremely low pressure by an efficient quick-acting vacuum pump.

We are naturally inclined to regard the atmosphere as the universal medium for the transmission of sound. Speech, music, and all the familiar noises of every day life are conveyed to the ear through the surrounding air. Solids and liquids are, however, excellent media for sound transmission as may be observed in numerous ways. The water-pipes in the house often carry the "singing" and "hammer" sounds which travel along the pipes from one room to another. The "string-telephone" exemplifies the passage of sound through a long wire tightly stretched. Certain "deaf cases" have been made to hear via the bones of the head, by holding one end of a stiff rod between the teeth, the other end being pressed into contact with the vibrating source, *e g*, a clock or a piano. Listening near the hull in a ship's cabin below the water line, the sound of the propeller of a neighbouring ship can be heard clearly—exemplifying the transmission of sound through the sea. If further proof is desired submersion of the observer's head in the water will be even more convincing.

Velocity of Sound.—The sound of thunder is not heard until some time after the lightning flash; the flash of a gun is seen before the report is heard; the puff of "white" steam from the whistle of a distant engine is observed before the sound arrives These, and many other examples might be quoted as evidence that sound takes time to travel and that its velocity is small compared with the velocity of light (186,000 miles per second). In air, sound takes nearly five seconds to travel a mile, in water about one second, and in iron or steel about a third of a second, *i e.*, it travels about fifteen times as fast in iron as in air. The experiment is easily tried on a long stretch of iron railing or piping—an observer at one end, listening to the sound of a blow on the other end, hears two blows, the first through the iron, the second through the air.

All kinds of sounds, high and low, loud and weak (with certain limited exceptions) travel with the same velocity in the same medium,—otherwise the music of a distant band would become confused on arrival at the listener's ears. Just as ripples spread outwards in two dimensions from a stone thrown into a pond, so waves of sound spread, in three dimensions, from a simple vibrating body through the surrounding medium. The movement of any particle of the medium, is, however, purely local, each particle making small to and fro excursions in a manner similar to that of the vibrating body itself. The local motion of the particles must be clearly distinguished from the motion of the disturbance which travels forward from layer to layer of the medium with an ever-increasing radius. It is the state of the minute to and fro motion which advances, the medium as a whole, after the disturbance has passed, being practically in its initial position. In this respect the motion is well exemplified by the ripples on a water surface. The sound waves, however, differ from the ripples in one important respect, viz. the vibratory motion takes place in the same line as the direction of advance of the wave, whereas in the case of the ripples the to-and-fro motion is *at right angles* to the direction of propagation of the wave. The former type of motion, as in the sound wave, is termed *longitudinal;* the latter, *transverse.* The general character of longitudinal wave motion may be demonstrated by means of a long helical spring (*e.g.*, 6 ft. long 4 inches dia. of wire ·06 in. thick) supported horizontally at frequent intervals by strong threads. If one end be moved to and fro longitudinally a corresponding motion will travel, like a wave, to the other end. Various effects of reflection, etc., with which we are not immediately concerned may also be demonstrated with this simple apparatus. It is a commonplace observation that any number of sound waves may cross the same airspace at the same time. No confusion arises due to this overlapping of the waves.

Receivers of Sound.—To complete the natural sequence of events a suitable receiver is required to collect the sound energy after transmission through the intervening elastic medium. When the sound travels through the atmosphere the ear forms a natural, though not always the most convenient, receiver. When liquids or solids transmit the sound other forms of receiver are generally to be preferred.

Order of Treatment.—From what has already been said it will appear that the physical basis of the theory of sound involves three fundamental considerations. First a vibrating body is essential to the production of sound; second, an elastic medium in contact with the vibrating body is required to transmit the vibrations to a distant point; and third, some form of receiver is necessary to absorb the energy from the medium and to reconvert it into a form of vibratory motion convenient for observation. We shall follow this order of treatment as far as practicable.

SOURCES OF SOUND

Vibrating Systems.—A fundamental advance in the theory of sound was made in 1843 when Ohm proved that the simplest and most fundamental type of sound sensation is that which corresponds to a simple harmonic motion, *i.e.*, to the simplest mathematical form of periodic function. (*See* HARMONIC MOTION.) Such motions may vary in period and amplitude but in no other manner; they are consequently ideal for the production of "simple" or "pure" tones. Another important feature of this form of motion is the possibility of transmission from one medium to another without change of form. Again, it has been proved by Fourier that the most complex form of periodic motion can be analysed (or synthesised) into a series of simple harmonic motions having frequencies which are multiples of that of the complex motion. The vibrations of a tuning fork may approximate closely to a simple harmonic motion, the resulting sensation being described as a "pure tone."

Simple Harmonic Motion (*see* WAVE MOTION) is typified by the oscillations of a particle attracted towards a fixed point O with a force varying as the distance x from O. If s be the force at unit distance from O, then at x it will be $-sx$, the sign of the force being always opposite to that of the displacement. Thus if m is the mass of the particle

$$m\partial^2x/\partial t^2 = -sx \quad \text{or, writing } n^2=s/m, \quad \partial^2x/\partial t^2+n^2x=0 \qquad (1)$$

of which the solution is

$$x=a\cos(nt+\epsilon) \qquad (2)$$

the constants a and ϵ are arbitrary. The motion is therefore periodic, the values of the displacement x, and the velocity $\partial x/\partial t$ of the particle recurring whenever nt increases by 2π. The *periodic time* of the oscillation is therefore

$$T = 2\pi/n = 2\pi\sqrt{(m/s)} \qquad (3)$$

a quantity independent of a. The type of vibration indicated by equation (2) is of fundamental importance. The equation shows that the particle oscillates between two points at a distance a on opposite sides of O. This distance a is called the *Amplitude* of the vibration. The quantity ϵ represents the initial *Phase* of the vibration when $t=0$. By simple differentiation of equation (2) we obtain the *velocity of the particle* $\partial x/\partial t=-an\sin(nt+\epsilon)$ and *the acceleration* $\partial^2x/\partial t^2=-n^2x$ as postulated in equation (1). The meaning of equation (2) for S.H.M. is often expressed graphically as the projection on a diameter of the motion of a point moving uniformly, with constant angular velocity n on a circular path of radius a, the periodic time (for one revolution) being $T=2\pi/n$. The reciprocal of the *Period* T, viz., $n/2\pi$, is termed the *Frequency*. The quantity n is sometimes called the *pulsatance*.

Practical demonstration of the relation between a simple harmonic motion and the corresponding circular motion, may be seen in any type of reciprocating engine; the motion of the piston in the cylinder is approximately simple harmonic whilst that of the flywheel is circular with uniform velocity. A simple pendulum, a weight suspended on a spring, a rapidly vibrating wire, tuning fork, or diaphragm all illustrate, approximately, simple harmonic motion; any differences in their motion arising from differences in frequency and amplitude only.

The relationship (3) for the periodic time of vibration is of very wide application in the theory of sound. It indicates the general principle that the period T increases with the "inertia" or mass factor m and decreases with the "stiffness" or "elastic factor" s (s being the force required to produce unit displacement). Thus in the case of a simple pendulum of length l, $s=mg/l$, whence the periodic time of an oscillation is $T=2\pi\sqrt{(l/g)}$. The period of vibration of a mass m on a helical spring of strength s is expressed directly by (3), viz. $T=2\pi\sqrt{(m/s)}$. We also obtain from (2), for the energy of the vibrating particle

$$\begin{aligned}\text{Mean kinetic energy}=\text{Mean potential energy}&=ma^2n^2/4\\ \text{Maximum energy}&=ma^2n^2/2.\end{aligned} \qquad (4)$$

The energy is a maximum at the mid-point and at the two turning points of the vibration. In the former case it is all kinetic and in the latter all potential energy.

When a single particle is acted on by a number of distinct forces, each of which would cause it to perform S.H.M., the question arises as to the resultant motion. A number of important cases require consideration:—I. *Vibrations of the Same Frequency and in the same straight line.* It may be shown that such a system of vibrations is reduced to a single resultant by means of a vector polygon, the angles representing relative phases, in exactly the same manner as a system of forces acting at a point. II. *Two Vibrations of nearly the same frequency and acting in the same straight line: beats.* This case has very important applications in sound and is of frequent occurrence. If two vibrations of the same amplitude and *nearly* equal frequency act together the resultant amplitude will at first be *double* the single amplitude. As the higher frequency vibration gains on the lower, however, thereby changing the relative phase, a point will be reached when they are in opposition and will neutralize each other (amplitude zero). This cyclic process goes on so long as both vibrations are maintained. If the two frequencies are N and $N+\partial N$, the resultant amplitude will vary between $2a$ and 0, the time interval between two successive maxima being $2\pi/\partial N$, *i.e.*, the *frequency, of the beats* will be ∂N, the difference between the two, nearly equal, frequencies. The phenomenon of beats is observed when two notes *nearly* in tune are heard together—a periodic rise and fall of intensity being noticed. As the beats between two notes increase in frequency a sensation of roughness or discord (*dissonance*) sets in, and ultimately two independent notes of the diatonic scale are recognised. The *beat effect* has direct application in the comparison of one sound frequency (*e.g.*, that of a vibrating string) with a standard of frequency such as a tuning fork. The well-known *heterodyne* of radio-telegraphy or telephony is a beat effect between two sets of radio-frequency (*e.g.*, 10^6 cycles per second) oscillations, slightly mistuned. The *beat-note* is adjusted to have any frequency, say 500 periods per second, which falls within the audible range. III. *Vibrations at right-angles.* In this case we are dealing with the motion of a particle on a plane surface. When the imposed vibrations have the same frequency, it is readily shown that the particle traces an elliptical path, which may vary from a straight line, when the phases differ by 180°, to a circle when the phases differ by 90° and the amplitudes are equal. (a). *Frequencies nearly equal.* In this case the particle follows a path which slowly changes through the various forms, straight line, ellipse, circle, etc., due to the slowly changing phase difference. The frequency of performance of a complete cycle of figures will, of course, be ∂N, the difference between the two nearly equal frequencies. (b). *Frequencies Commensurate.* 2:1, 3:1, 4:1, etc. Here again the particle traces out a curve having a certain number of loops—this number being equal to the ratio of frequencies. For *nearly* commensurate frequencies the curve slowly changes as the phase difference varies. Numerous mechanical devices have been designed for drawing automatically the various "harmonic" curves obtained by compounding two or more harmonic vibrations. These generally consist of two compound pendulums controlling a common writing point, and each capable of performing simple harmonic motion in one or possibly two directions simultaneously. Beautiful and fascinating designs may be traced in this way.

An optical method of exhibiting a small difference of frequency between two tuning forks was devised by J. A. Lissajous (1822–

·880). A small mirror is attached to one prong of each fork, one of which vibrates in a vertical plane and the other horizontally. A narrow pencil of light is reflected successively from the two mirrors and falls on a screen. When the forks vibrate together the spot of light on the screen traces out the "resultant" curve of the two vibrations. If the two forks have the same frequency the figure is a stationary ellipse; if they differ slightly in frequency, the ellipse assumes successively the various forms including a straight line and a circle. These figures are known as *Lissajous figures*. The same principle may, of course, be applied to any two systems vibrating at right angles with approximately equal, or commensurate, frequencies. Recently Dye has employed the cathode-ray oscillograph for the harmonic comparison of very high electrical frequencies (of the order 10^6 p.p.s.).

Fourier's Theorem.—*Summation of any number of simple harmonic-vibrations of commensurate frequencies. Synthesis and analysis of complex wave-forms of vibration.* This very important theorem due to J. B. J. Fourier (*Theorie de la Chaleur*. Paris, 1822) asserts that *any single-valued periodic function whatever can be expressed as a summation of simple harmonic terms having frequencies which are multiples of that of the given function.* (*See* HARMONIC ANALYSIS.) The theorem not only deals with the synthesis of a complex form of vibration, but also indicates a method of analysis of such a vibration into its component simple vibrations or harmonics. Thus if x is the resultant displacement at a time t, in a complex vibration of frequency $n/2\pi$,

$$\begin{aligned} x=f(nt)=A_0+A_1\cos nt+A_2\cos 2nt+\ \ldots\ +A_r\cos(rnt) \\ +B_1\sin nt+B_2\sin 2nt+\ \ldots\ +B_r\sin(rnt). \end{aligned} \tag{6}$$

By suitable choice of the amplitude-values A_0, A_1, etc., B_1, B_2, etc., it is possible to analyse or synthesise any form of *single-valued periodic vibration.* Thus the displacement curve represented by fig. 1 (a), may be obtained by adding a sufficient number of odd terms of a sine series. In fig. 1 (b) the first, third and fifth terms are added, in fig. 1 (c) the first fifteen odd sine terms are added. It will be seen that (c) approximates closely to (a), the more terms taken the more nearly does the synthesised curve approach the ideal. The mathematical analysis or synthesis of complex wave-forms may become very laborious. In order to simplify the process various mechanical "*harmonic analysers*" have been constructed (*see* Millar's "Science of Musical Sounds") which perform the necessary mathematical integrations, by a direct mechanical process. Fourier's theorem and harmonic analysis have a wide field of application not only in the study of sound-vibrations, but in astronomy, meteorology, tide prediction, mechanical and electrical engineering.

Loudness, Pitch and Quality. Intensity, Frequency and Wave-form.—Sounds differ from one another in three respects.

(i) *Loudness and Intensity.*—These two terms refer to the subjective and physical aspects respectively. The intensity of a sound refers to a definite physical quantity which determines the rate of supply of vibrational energy (proportional to [amplitude]). Loudness corresponds to the degree of sensation, being

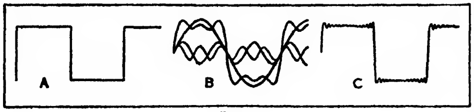

FIG. 1

dependent both on the intensity of the sound and the sensitiveness of the ear under the particular conditions. Near the limits of audibility *loudness* may be very feeble although the intensity be very great. The sensation of loudness varies over a relatively small range for enormous variations of intensity. An ear which can detect a feeble watch tick remains undamaged by a neighbouring explosion—although the range of intensity involved in these examples may be greater than 10^{12} to 1. The relation between sensation (loudness) and stimulus (intensity or amplitude) is generally expressed by Weber's law—"The increase of stimulus necessary to produce a just perceptible increase of sensation is proportional to the pre-existing stimulus." This law indicates a rapid diminution of sensitiveness of the ear with increase of total intensity of the sound.

(ii) *Pitch and Frequency.*—The frequency of a regular or periodic vibration is the number of vibrations performed per second. Musical sounds arrange themselves in a natural order according to *pitch*. The latter depends solely on the *predominant frequency* of the vibrations—the greater this frequency the higher the pitch—and on the number of these vibrations reaching the ear per second. The latter stipulation is made to include sounds received from sources of sound in motion. This relation between pitch and frequency is simply verified by means of a revolving toothed wheel striking the edge of a card which produces a sound whose predominant frequency is proportional to the product of speed (revolutions per second) and the number of teeth on the wheel. For a given note the predominant frequency is the same whatever the source of the note, and the ratio of the frequencies of two notes forming a given musical interval is the same in whatever part of the musical range the two notes are situated. The more important consonant *intervals* with their frequency ratios are Unison 1:1, Major Third 5:4, Fifth 3:2, Major Sixth 5:3, Minor Third 6·5, Fourth 4:3, Minor Sixth 8:5, Octave 2:1. Notes whose frequencies are multiples of that of a given one, the *fundamental*, are called *harmonics*. The frequency ratios defining each note of the *diatonic musical scale* are

C	D	E	F	G	A	B	C
1	9/8	5/4	4/3	3/2	5/3	15/8	2

The same series of ratios applies to any octave which may be chosen.

(iii) *Quality and Wave-Form.*—Sounds of the same pitch and loudness, but produced by different means, are distinguished by their quality. Thus the same note produced by a voice, a piano, or a violin, would have distinct characteristics which are at once recognisable by the ear. Very few sounds can be regarded as "pure," that is, free from overtones. The presence or absence of these overtones decides the *quality* of the sound. A tuning fork emits almost a pure tone whereas a violin note is rich in overtones characteristic of the instrument. Quality depends therefore on wave-form. Fourier's analysis of the wave-form of the sound emitted by a particular instrument tells us which harmonics are present and their relative importance.

Forced Vibrations, Damping, Resonance.—On account of the dissipation of energy by forces of a frictional nature, a vibrating body if left to itself, is gradually brought to rest. Its vibrations may be maintained, however, by the application of a suitable periodic force, which supplies the energy dissipated by friction and sound radiation. It is important to consider the relation between the frequency of such a force and the frequency of the free or natural vibration of the body. It is generally assumed that for small oscillations the frictional forces are proportional to the velocity of the particle. Consequently the equation of forces becomes

$$m\frac{\partial^2 x}{\partial t^2}+r\frac{\partial x}{\partial t}+sx=F\cos pt \tag{7}$$

where $F\cos pt$ represents the external periodic force of maximum value F and frequency $p/2\pi$, r is the resistance per unit velocity and s the restoring force per unit displacement. Writing $s/m=n^2$, $F/m=f$ and $r/2m=k$ it can be shown that the displacement x is given by

$$x=\frac{f\sin\epsilon}{2kp}\cos(pt-\epsilon)\quad\text{where}\quad\tan\epsilon=\frac{2kp}{(n^2-p^2)} \tag{8}$$

representing the *forced vibration* of period $p/2\pi$ and amplitude $f\sin\epsilon/2kp$. In the case where there is no friction, the *damping constant* $k=0$, $\sin\epsilon=\tan\epsilon=0$, $\epsilon=0$ or π, and

$$x=\frac{f}{(n^2-p^2)}\cdot\cos pt \tag{9}$$

Amplitude of Forced Vibrations.—In the steady state of maintained oscillations, equations (8) and (9) represent the resultant *forced* motion. The amplitude A of the motion, is given by

$$A=\frac{f\sin\epsilon}{2kp}=\frac{f}{\{(n^2-p^2)^2+4k^2p^2\}^{\frac{1}{2}}}\left(\text{Since }\sin\epsilon=\frac{2kp}{\{(n^2-p^2)^2+4k^2p^2\}^{\frac{1}{2}}}\right). \tag{10}$$

This expression is of fundamental importance. The amplitude A is a maximum when the denominator of the expression is a minimum, *i.e.*, when $p^2=n^2-2k^2$ (provided $n^2>2k^2$); the maximum value being then

$$A_{\text{max.}}=f/2kn. \tag{11}$$

In the case where there is *no damping* ($k=0$), and the free frequency n is the same as the forced frequency p, it will be seen that the amplitude A becomes *infinite*. Such a case of course never occurs in practice, for the damping k is never zero. For *moderate values of damping* ($n^2>2k^2$), the forced amplitude $A_{\text{max.}}$ (equation [11]) is greatest when the forced frequency coincides with that of the free vibration, and may become very large when k is small. This condition is known as *resonance*. When dealing with sources of sound, we shall have occasion to refer frequently to resonant vibrations.

Phase of Forced Vibrations.—The force and the resultant forced vibrations are not necessarily in phase. From equation (8) we see that $\tan\epsilon$ is always positive when p is less than n, that is ϵ lies between 0 and $\pi/2$ when the forced frequency is less than the free frequency, and $\tan\epsilon$ is always negative when p is greater than n, that is, ϵ lies between $\pi/2$ and π when the forced frequency is greater than the free frequency. *At resonance*, when $n=p$, $\tan\epsilon=\infty$ and $\epsilon=\pi/2$, *i.e.*, the force and the displacement are "in quadrature" whilst the force and velocity are "in phase." *Away from resonance, if the damping is small*, the phase difference ϵ will, in general, be nearly equal to 0 or to π, that is, *the displacement will be in phase or out of phase with the force according as the frequency of the force is less or greater than the frequency of the free vibrations.* These phase effects are beautifully demonstrated by means of a frequency meter of the vibrating reed type, viewed intermittently at, or very near, the frequency of excitation. The graduated series of reeds appear as in fig. 2 (a) when viewed in the ordinary way, but as in fig. 2 (b) when viewed intermittently. In accordance with the theory, the reeds on opposite sides of the resonant one are seen to be in opposite phase, with the resonant reed intermediate.

Power Dissipation.—In order to maintain vibrations against damping forces, a certain rate of energy supply is necessary. This is measured by the product of the force $f\cos pt$ and the

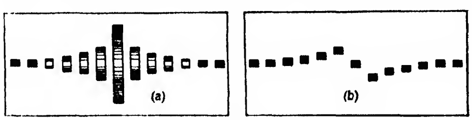

FIG. 2

particle velocity $\partial x/\partial t$ (obtained by differentiating equation [2] with respect to t). The mean power required to maintain vibrations is thus found to be

$$W=\frac{f^2}{4k}\cdot\sin^2\epsilon \tag{12}$$

This reduces to zero when $\epsilon=0$ or π *i.e.* when $k=0$ (*see* equation [10]). In the case of *damped vibrations at resonance the power dissipation is a maximum for*

$$\epsilon=\pi/2, \quad \text{whence} \quad W_{\text{max.}}=f^2/4k \tag{13}$$

Sharpness of Resonance.—The effect of damping becomes relatively more and more important as resonance is approached. At resonance the amplitude and power dissipation reach a maximum. The ratio of power dissipation W under specified conditions to that at resonance is given by

$$\frac{W}{W_{\text{max.}}}=\sin^2\epsilon=\frac{4k^2}{\left(\frac{n^2-p^2}{p}\right)^2+4k^2} \quad [\text{from } (4)]$$

a relation indicating how the power required to maintain vibrations against frictional and radiation losses varies near resonance. It will be seen from (14) that *the energy dissipated* at a frequency $p/2\pi$, near resonance, *is half the resonance value when*

$$\left(\frac{n^2-p^2}{p}\right)^2=4k^2,$$

that is when

$$(n-p)=\pm k \text{ (approx.)} \quad \text{or} \quad \frac{p}{n}=1\pm\frac{k}{n}, \tag{15}$$

i.e., when the frequency of the force differs from that of the resonator by the fraction k/n. This ratio k/n therefore constitutes a measure of the *sharpness of resonance*. The reciprocal of the ratio, *i.e.*, n/k is sometimes referred to as the "persistence" of the vibrations. The smaller the damping k and the higher the natural frequency n, the sharper will be the tuning, and the greater the persistence of the vibrations. This principle has many striking and important applications. Thus in frequency standardisation, *e.g.*, of tuning forks or quartz resonators, very great accuracy of tuning is essential, and the damping must be extremely small. In other cases, *e.g.*, the faithful reception or reproduction of sound vibrations over a range of frequencies, resonance is distinctly undesirable, and the system must have a natural frequency ($n/2\pi$) removed as far as convenient from any possible values of the forced frequency ($p/2\pi$), or, alternatively, the system must be heavily damped (k large).

The damping constant k of a vibrating system is determined by direct measurement of the rate of decay of its free oscillations (from $A_2=A_1e^{-k\tau}$, or $\log A_1/A_2=k\tau$ where A_1 and A_2 are successive amplitudes on the same side and τ is the periodic time $-k\tau$ is known as the *logarithmic decrement* of the oscillations). The damping coefficient k may be determined alternatively from observations of the sharpness of resonance.

Electrical Oscillations.—Alternating electrical and magnetic effects provide a very convenient means of exciting the corresponding mechanical vibrations. The advent of the thermionic three-electrode valve, as a simple means of producing electrical oscillations over a wide range of frequency and power, has greatly assisted in the rapid development in the design of electrical sound sources, and in electrical methods of receiving and recording sound waves. There is a close analogy between electrical and mechanical oscillations. If we replace inertia (mass) m in the mechanical system by inductance L in the electrical system, mechanical resistance r by electrical resistance R, spring factor (or stiffness) s by 1/capacity ($1/C$), displacement x by quantity Q, velocity $\partial x/\partial t$ by current $i=\partial Q/\partial t$, acceleration $\partial^2x/\partial t^2$ by rate of change of current $\partial^2Q/\partial t^2$—the electrical equations become identical with the corresponding mechanical equations. Thus the electrical equation for the forced oscillations of a circuit containing inductance L, capacity C, and resistance R, is

$$L\frac{\partial^2Q}{\partial t^2}+R\frac{\partial Q}{\partial t}+\frac{Q}{C}=E\cos pt \tag{16}$$

which is analogous to equation (7) for a mechanical system. With the substitutions mentioned above (with $k=L/2R$ and $f=E/L$) the solution of this equation is similar to equation (8) and the subsequent remarks relative to resonance and damping apply also to the electrical system. The frequency of free vibration of a mechanical system is $N=\frac{1}{2\pi}\sqrt{(m/s)}$ (*see* equation [3]), and the corresponding frequency of electrical oscillations is $N=\frac{1}{2\pi}\sqrt{LC}$. This is also the frequency at resonance in the case of forced vibrations provided the damping k and resistance

R are not exc e.

For the various methods of generating alternating currents, *e.g.*, by valve oscillators, interrupters, alternators, etc) the reader should consult the article on WIRELESS TELEGRAPHY.

Motional Impedance.—On account of the extensive use of electrical forms of sound generators and receivers it is very important in design to have a knowledge of their characteristics In any form of machine which converts electrical energy into motion the moving mechanism reacts on the electrical circuit Thus the revolving armature of an ordinary electric motor generates what is called a "back e m f." in opposition to the applied voltage. This back e m f may alternatively be regarded as an increased resistance to current flow in the armature, the efficiency of the motor being measured by the ratio of this resistance R relative to the total resistance $(R+r)$ in the circuit, the net power used in the motor being a maximum when $R=r$, in which case the efficiency is 50 per cent In a similar manner the mechanical vibrating element of an electrical sound generator or receiver reacts on the electrical circuit, the back e.m f. due to the vibration appearing as a change of impedance of the circuit. The change of impedance due to this cause is termed *motional impedance* and, relative to the total impedance, is a measure of the efficiency of the sound generator.

Transverse Vibrations of Strings.—When any point of a thin flexible wire stretched between two fixed clamps or bridges is displaced transversely and released, the wire commences to vibrate. This vibration results from transverse motions travelling in opposite directions along the string and successive reflections of these motions from the fixed ends. In order to visualise such reflection of a transverse motion it is well to make a few simple experiments on waves travelling along a stretched rope, one end of which is held in the hand whilst the other end is fixed It will be observed that the movement of each particle of the rope when forming part of the reflected wave is in the opposite direction to its motion in the original wave. The rope assumes the form of a sine wave if the end is moved up and down harmonically. Before we can deduce the modes of vibration of a stretched string it is necessary to know the velocity with which a wave of displacement travels along the string and also the manner in which the direct and reflected waves affect each other to produce what are called stationary waves.

Velocity of a Transverse Wave Along a String.—The following method is due to Tait. The string is supposed to be drawn through an imaginary smooth tube with velocity c. The tube is straight except for an isolated curved portion which represents the wave on the string. If R is the radius of curvature at any point of the tube, the force acting in the direction of the normal to an element δs is $T\delta s/R$ where T is the tension in the string Now the centrifugal force of the element δs, of mass m per unit length, and velocity c will be $m\delta s\, c^2/R$, and this must balance the force $T\delta s/R$ if there is to be no reaction on the tube. Thus if $T\delta s/R=m\delta s\cdot c^2/R$, then $c=\sqrt{(T/m)}$ and there is no reaction on the tube, *i.e.*, the tube may be regarded as absent and *the wave travelling along the string with the velocity* $c=\sqrt{(T/m)}$.

Reflection. Formation of Stationary Waves. (See WAVE MOTION.)—If both ends of the string of length l are fixed, the wave is reflected successively from end to end, and the resultant motion is determined by the superposition of the direct, or *incident wave*, and the *reflected wave*. The resultant displacement y at the instant t of a point distant x from one end will be $y=f(ct-x)-f(ct+x)$ where f indicates "a function of" Since $y=0$ when $x=l$ we have also $f(ct-l)=f(ct+l)$, or $f(z)=f(z+2l)$ where $z=(ct-l)$, which indicates that z is a periodic function repeating at intervals of $2l$ Consequently the displacement at any point of the string is periodic, the period $T=2l/c$ being the time taken for a wave to travel along the full length of the string and back again. The frequency of this form of vibration is consequently $N=c/2l$ where $c=\sqrt{(T/m)}$, *i.e.*,

$$N=\frac{1}{2l}\sqrt{\frac{T}{m}} \tag{17}$$

If the displacement y varies sinusoidally with a frequency $n/2\pi$, we have $y=a\cos n(t-x/c)-a\cos n(t+x/c)$ which reduces to

$$y=2a\sin nt\ \sin(nx/c) \tag{18}$$

At any point x on the string the amplitude is therefore $2a\sin nt$, varying sinusoidally with time between zero and $2a$ The amplitude of successive particles is also varying with x according

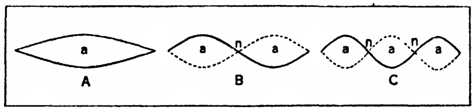

FIG 3

to a sine law. The result is a series of loops on the string of amplitude 0 to $2a$. The condition for the formation of loops on a string of finite length l is clearly that in which *l is a whole multiple of the length of a loop*, *i e*, provided the number of loops is 1, 2, 3, · · · etc. The *fundamental* frequency n of the string is given by (17), the various possible overtones are simple multiples of n, *i e*, they form a harmonic series The modes of vibration of a string vibrating with 1, 2, 3 loops is shown in fig 3 The points marked n which are permanently at rest during the vibrations, are called *nodes*, whilst the points marked a where the amplitude is a maximum are called *anti-nodes* or *loops* It will be evident that the string could be clamped at the nodes n without affecting the motion of the remainder of the string Denoting the *wave-length* of the vibration by λ we must have $N'\lambda=c=\sqrt{(T/m)}$ whence the frequency

$$N'=\frac{s}{2l}\sqrt{\frac{T}{m}} \tag{19}$$

s being the number of loops, *i e*, half wave-lengths, into which the string of length l is divided

The string may vibrate with any of the frequencies given by equation (19) at the same time, *i e*, a note may be produced which is made up of the fundamental and a number of harmonics. The laws of a vibrating string indicated by equation (19) may easily be verified by means of a *monochord* or *sonometer*, which consists essentially of a thin metallic wire (*e g*, steel piano wire) stretched over two bridges by means of a weight hanging over a pulley, or by a spring tensioning device A movable bridge provides a convenient means of varying the vibrating length of the wire The monochord is a very *useful means of comparing frequencies*—the frequency of the string being inversely proportional to the vibrating length. Exact tuning is indicated by the "beats" between the monochord note and the note compared with it. The various overtones of a string may also be very simply demonstrated by means of the monochord, the string being lightly damped at any point corresponding to a node and plucked or bowed at a point corresponding to an antinode of the overtone required to be excited The positions of the antinodes are easily determined by means of little paper riders.

Stiffness of Strings and Yielding of Supports.—When the thickness of the string becomes appreciable in relation to the length of a loop, the stiffness may have a perceptible effect on the frequency of vibration—this effect becoming more and more important the higher the overtone excited (*i e*, the greater the number of loops). Where great accuracy is required a modification of equation (19) is necessary, viz

$$N=\frac{s}{2l}\sqrt{\frac{T}{m}}\left\{1+\frac{\pi^3 s^2 r^4 E}{8l^2 T}\right\}$$

where r is the radius of the circular section of the wire and E Young's modulus of elasticity for the material Yielding of the "bridges" supporting the wire may have the effect of increasing or decreasing the frequency according as the supports have (a) very large mass M but small spring factor or (b) very large spring factor μ and negligible mass The effects of (a) and (b) are equivalent to a change of length of the string in the ratios $1:(1-2Tl/Ma^2s^2\pi^2)$ and $1:(1+2T/\mu l)$ respectively.

Methods of Producing Vibration in Strings. Quality.—A stretched string may be set in vibration by numerous methods. Plucking, bowing and striking are the more familiar; exemplified in the harp, the violin, and the piano, respectively. A string may also be set in vibration by forced oscillation of a point of support, *e.g.*, if one end is attached to the prong of a vibrating tuning fork (Melde's experiment). Electromagnetic methods may also be used to excite a metallic string. In one of these methods a light metal wire is attached at right angles to the vibrating wire and arranged to dip in a small cup of mercury at each downward movement. A current passing through this intermittent contact actuates a small electromagnet which maintains the wire in vibration in the same manner as an electric bell is operated. In another method the vibrating wire itself carries an alternating electric current and lies in a permanent magnetic field. When the frequency of the current and position of the magnet are suitably chosen one of the numerous possible overtones of the wire will be readily excited. It will be appreciated that the method of excitation has a very important influence on the form of the wave which travels along the string. The quality of the note is of course dependent on this wave form, *i.e.*, on the relative amplitudes of the various overtones present in the vibration. It is just this addition of overtones to the fundamental which makes it possible for the ear to distinguish between the sounds of a piano, a violin, and a harp, emitting the same fundamental note.

Strings as a Source of Sound: The Sounding Board.—A vibrating wire *rigidly* supported would radiate extremely little sound energy to the surrounding air on account of the local reciprocating flow of air between opposite sides of the vibrating wire. It is necessary in an efficient stringed sound source that the bridges should yield and communicate the vibrations to a surface of large area, *i.e.*, to a sound board, in contact with the medium. This sound board is therefore a vital part of all stringed musical instruments—it is important, however, in a good instrument, that the sounding board should have no predominant resonance frequencies of its own, otherwise these would reinforce disproportionately the corresponding frequencies of the strings.

Transverse Vibrations of Elastic Rods.—The vibrations of a stretched wire are controlled by the tension whilst the stiffness of the wire may generally be disregarded. In the case of a relatively thick wire or rod the stiffness may become all-important and tension may ultimately be disregarded. Even when simplified as far as possible the theory of transverse vibrations of elastic rods is very complex in comparison with the theory of strings. In the case of strings, harmonic waves travel with a velocity independent of wave-length but in the case of rods or bars this is not so. It is shown in textbooks of sound (*see* Bibliography) that the velocity of a transverse elastic wave in a rod is proportional to $t\cdot\sqrt{(E/\rho)}\cdot/\lambda$ where t is the thickness in the direction of displacement, E elasticity, ρ density, and λ the wave-length. The velocity is thus dependent on the wavelength, a fact which makes the theory much more complex. It may be shown that the possible frequencies of transverse vibration of a bar are given by

$$N = C\frac{k}{l^2}\sqrt{\frac{E}{\rho}} \qquad (20)$$

where k is the radius of gyration of the section of the bar about the neutral plane, and l is the length of the bar ($k^2 = t^2/12$ for a rectangular bar of thickness t). The value of the constant C depends on the method of supporting or clamping the bar and on the overtone to be excited. *The frequency is therefore proportional to the velocity of longitudinal waves* [$\sqrt{(E/\rho)}$] *in the material of the bar. It also varies as the thickness (or radius) and inversely as the square of the length of the bar.* As in the case of strings, stationary waves are set up in rods by the combined effects of the direct and reflected waves. The possible forms of these stationary waves depend on the method of supporting the rod. Some of the modes of vibration of a *free-free rod*, *i.e.*, entirely free or supported at two nodes, are shown in fig. 4a; whilst fig. 4b illustrates those for a *clamped-free bar*, *i.e.*, a bar fixed in direction at one end and free at the other.

In the case of the *free-free bar* the constant C in equation (20) for the frequency is equal to $\frac{\pi}{8}(4s \pm 1)^2$ where s may be 1, 2, 3, etc. *i.e.*, the possible frequencies are proportional to the squares of the successive odd numbers commencing at 3. *For a clamped-free bar* the constant C in equation (20) is approximately equal to $\frac{\pi}{8}(4s \pm 1)^2$ where s may be 0, 1, 2, 3, etc. More accurate values for $(4s \pm 1)$ in the case of the fundamental ($s=0$) and the first overtone ($s=1$) are 1·1937 and 2·9884 respectively. The

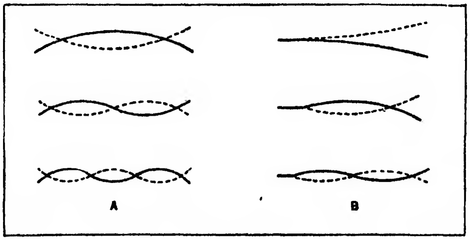

FIG. 4

frequencies of the first three tones relative to the fundamental are consequently 1, 6·25 and 17·6 approximately. The relation $N \propto k\cdot\sqrt{(E/\rho)}/l^2$ has been experimentally verified by a number of physicists, both in the case of the free-free and the clamped-free bar.

Applications and Methods of Excitation.—As in the case of strings the transverse vibrations of a bar may be excited by striking, plucking, bowing, or by electromagnetic means, the partials present, and consequently the quality of the note being dependent on the method of excitation. The only method of supporting a bar which yields "harmonic partials" is the free-free method, which has application in a musical instrument known as the "harmonicon" or "dulcimer" in which freely supported bars of graded lengths are struck by a hammer, thus producing an agreeable succession of musical tones. Thin rods or reeds, clamped at one end and excited by plucking, are used in the "musical box" so well known. Used in combination with suitable air cavity resonators, clamped-free reeds are fitted in various musical instruments, notably the clarinet group. The combined action of an air blast and a vibrating reed is illustrated in the concertina and the harmonium, whilst in the reed pipes of an organ the reed is combined with a resonant air column. The reed of the telephone earpiece designed by S. G. Brown is operated electromagnetically. It is used in an almost unstable condition, the pull of a permanent magnet being nearly sufficient to overcome the stiffness of the reed. This results in a large increase of sensitiveness to the superposed alternating magnetic field.

Frequency Meters form a good example of the electro-magnetic or direct mechanical excitation of reeds. The frequency meter consists essentially of a graded series of clamped steel reeds actuated by a common electro-magnet supplied with alternating current of which the frequency is required. Such instruments have been made covering various ranges from 1 or 2 to 1,500 cycles per second. The frequency of a clamped-free bar may be lowered either by loading the free end or by reducing the cross section near the clamped end. The frequency may be raised either by shortening the bar or reducing the cross section near the free end.

Tuning Forks.—On account of its great purity of tone and constancy of frequency the tuning fork is generally regarded as a standard of frequency and pitch. During recent years it has increased enormously in importance as a frequency standard for controlling electrical circuits, in such a manner as to form an electrical standard of great accuracy and of extensive range.

The tuning fork may be regarded either as a development from a free-free bar bent into the form of a U, or as consisting of a pair of symmetrical clamped-free bars attached to a common block of metal. Numerous patterns are in existence approximating to one or other of these two forms. It will be sufficient here to regard each prong as a clamped-free bar. In consequence of the oscillation of the centre of gravity of the two bars as they vibrate there will be communication of vibration to the block to which they are clamped. To reduce the amplitude of this vibration, which is in the direction of the prongs, the block must be firm and massive. The frequency of a fork of this construction with prongs of rectangular section of thickness t will therefore be

$$N=(1\cdot 1937)^2\cdot\frac{\pi}{8}\cdot\frac{t}{\sqrt{12}\cdot l^2}\sqrt{\frac{E}{\rho}} \qquad (21)$$

that is, $N=8\cdot 24\times 10^4 t/l^2$ if the prongs are of steel in which $\sqrt{(E/\rho)}=51\times 10^4$ cms./sec. *The frequency of a fork will therefore vary directly as the thickness of the prongs and as the velocity of sound in the material, and inversely as the square of the length of the prongs.* The first and second overtones of a fork will have frequencies $6\cdot 25N$ and $17\cdot 6N$ respectively. These overtones may easily be excited in a large fork by bowing at suitable points

The fundamental tone of a tuning fork may be selectively reinforced by attaching the stem to a *resonance box* of the same frequency—the overtones of the fork and the air cavity are widely different and do not reinforce each other. Two forks of nearly the same pitch may be compared by the method of beats, which gives in a very simple and direct manner the difference in frequencies. This method is also useful in studying the effect of temperature on the frequency of a fork—the one fork is kept under standard conditions whilst the temperature of another is varied. The temperature coefficient of frequency for a steel fork determined in this way is approximately -10^{-4} per degree C rise of temperature. The temperature coefficient of a fork made of elinvar steel is about one tenth of this.

Electrically Maintained Forks.—The vibrations of a low-frequency fork may readily be maintained by means of electrical contacts controlled by the prongs and an electro-magnet situated between them. The mode of operation is similar to that of an electric bell. Forks of higher frequency (of the order of 1,000 p.p.s) are maintained by means of electromagnets arranged in a special form of 3-electrode valve circuit devised by Eccles. Electrically maintained forks may be used to drive what are known as *phonic motors* (*see* Rayleigh's Sound, Vol. I., p. 67), the vibratory motion of the fork being thereby converted into a rotary motion of combined accuracy and constant speed. Electrically maintained forks and phonic motors, with their applications in standard frequency determinations, are described in A. B. Wood's *Textbook of Sound.* Forks are now in common use as sub-standards of time. The period of a fork is a very constant quantity and serves as a convenient sub-division of a second when time intervals have to be measured with accuracy. As a consequence of the increased application of the tuning fork for this purpose, methods have been devised for increasing the accuracy and perfection of electrically maintained forks. Low-frequency forks of this character giving an accuracy greater than 1 in 10,000 are in common use. If particular care is taken with the choice of material, design, and control of the fork, an accuracy of 1 in 10^6 or even 1 in a million is possible.

Electrically maintained forks of this nature are used to control electrical "multi-vibrator" circuits which serve as frequency standards for all frequencies which are multiples of that of the fork, *e.g.*, in steps of 1,000 cycles, up to $1\cdot 5$ million cycles per second. The tuning fork thus functions as a standard of radio-frequencies. It is possible to maintain an electrically driven fork by means of the "seconds" contacts of a standard pendulum clock. Such *clock controlled forks* are not subject to temperature variations, etc., and remain accurately in step with the standard clock over relatively long periods of time.

Longitudinal Vibrations of Rods.—When a rod is set into longitudinal vibration its axis remains undisplaced whilst cross-sections vibrate to and fro in the direction of the axis of the rod. The quantities involved are the density of the material and its elastic properties. Consider a rod of cross section A and an elementary slice of it bounded by two planes at x and $x+\delta x$ at right angles to the axis x of the rod. If the plane at x is displaced at the time t to $x+\xi$ the plane at $x+\delta x$ will be displaced to $x+\delta x+\xi+d\xi/dx\cdot\delta x$, that is, the actual elongation of the slice is $d\xi/dx\cdot\delta x$ and its fractional elongation $d\xi/dx$. This change in thickness of the slice implies a difference in the forces acting on its faces. The total force acting on the face at x will be $EA d\xi/dx$ where E is Young's Modulus of elasticity. Similarly at the opposite face of the slice the force will be in the opposite sense and equal to $EA(d\xi/dx+\delta x\cdot d^2\xi/dx^2)$. Consequently the resultant force acting on the slice will be $EA\ \delta x\cdot d^2\xi/dx^2$. Now the mass of the slice is equal to $\rho A\delta x$, where ρ is the density of the material, and the acceleration is $d^2\xi/dt^2$. We have therefore

$$\rho A\delta x\cdot\frac{d^2\xi}{dt^2}=EA\frac{d^2\xi}{dx^2}\cdot\delta x \quad\text{or}\quad \frac{d^2\xi}{dt^2}=\frac{E}{\rho}\cdot\frac{d^2\xi}{dx^2} \qquad (22)$$

an equation of the same form as that obtained for the transverse motion of a string, indicating a *wave travelling along the rod with velocity* $c=\sqrt{(E/\rho)}$ The above treatment is approximate only, since it ignores lateral bulging or contracting of the sides of the rod. The result is, however, sufficiently true provided the wave length λ is great compared with the width or thickness of the rod. As in the case of vibrating strings the direct and end-reflected waves in a rod of finite length form stationary waves with nodes and antinodes in accordance with the relation $c=N\lambda=\sqrt{(E/\rho)}$ or $N=\frac{1}{\lambda}\cdot\sqrt{(E/\rho)}$ In the fundamental mode of vibration of a free bar $\lambda=2l$ and the various partials require $s\lambda=2l$. Consequently the expression for the frequencies of the partial tones is

$$N=\frac{s}{2l}\sqrt{\frac{E}{\rho}}, \qquad (23)$$

which is similar to equation (19) for strings, the tension T being now replaced by the elasticity E *When the bar is clamped at the mid point,* an important practical case, *all partials requiring an antinode at that point are suppressed,* consequently only the odd partials are present It will be seen that *the partials* given by (23), *form a harmonic series*—provided $\lambda/2$ is always large compared with the diameter or thickness of the rod and that lateral bulging and shrinking may be neglected

The frequency of longitudinal vibrations in bars is usually very high compared with that of the transverse modes, the ratio increasing rapidly as the diameter or thickness diminishes relative to the length. The nodes of a bar vibrating longitudinally are points of maximum stress, whereas the antinodes are points of zero stress. Biot and Tyndall demonstrated this fact to a large audience by means of passing polarised light through the node of a vibrating strip of plate glass. The analyser was set at extinction before the rod was set in vibration so that no light was seen on the screen. On stroking the rod with a resined cloth vigorous vibrations were set up and intermittent light was passed on to the screen No such effects were observable at the antinodes where there is no stress.

Methods of Excitation.—Rods of metal, wood, or glass, clamped at the midpoint or at one end, are readily set in vibration by the steady frictional drag of a resined cloth drawn, with a moderate pressure, along the rod towards an antinode. Another method, more suitable for relatively short stiff rods, is to strike the end a sharp blow with a hammer. This method usually results in a complex sound due to both transverse and longitudinal vibrations—the one or the other may be rapidly damped out by clamping at a suitable point.

Electrical Methods of Excitation.—Powerful longitudinal vibrations may be set up in bars of magnetic material by acting on them with alternating magnetic fields of the resonating frequency. Using a small alternating current magnet (with iron wire core) mounted close to the end of a steel bar, the funda-

mental and harmonics can readily be excited as almost pure tones. The resonance is extremely sharp (indicating very small internal damping) and careful tuning is required. Vibrations have been obtained in non-magnetic rods by electrostatic methods (J. H. Vincent, *Nature*. Dec. 31, 1927) the end of the vibrating rod forming one plate of a condenser supplied with high frequency alternating current from a valve oscillator[1]. (*See* THERMIONIC VALVE.)

Longitudinal Vibrations of High Frequency in Piezo-Electric Crystals.—Certain crystals, notably quartz and rochelle salt, have the property of changing their linear dimensions when subjected to electrostatic stress, and conversely they develop electrical charges on their faces when mechanically strained. The phenomenon is known as piezo-electricity (discovered by P. Curie, 1880). The best effects are obtained when slices or rods of the crystal are cut in certain specified directions relative to the optic axis. Voltage applied to the faces at the ends of the electric axis produces a change of thickness and length of the crystal. If alternating voltage is applied, the thickness and length fluctuate accordingly, the maximum effects being produced when the frequency of the electrical alternations coincides with the natural frequency of longitudinal elastic vibration. W. G. Cady (*Phys. Rev.*, *19*, p. 1, 1922) has made use of this property of a quartz crystal in the construction of *standards of high frequency*, with particular application to radio-frequency standardisation. A special electrical circuit which we need not consider here was employed to detect the resonance in the quartz. Thus Cady found that a *quartz resonator* 30x4x1·4 m.ms. vibrating longitudinally in the direction of its length had a fundamental frequency of 89,870 cycles per second. The tuning was so sharp that a change of frequency of 1 cycle per second was measurable. The overtones were also excited and found to approximate to harmonics of the fundamental. G. W. Pierce (*Proc. Amer. Acad.*, Vol. 59, Oct. 1923 and Vol. 60, Oct. 1925) has succeeded in controlling the frequency of an oscillating valve by means of such a crystal. In this manner a *quartz oscillator* may be used as a *frequency stabiliser* for radio purposes.

Quartz plates vibrating longitudinally in the direction of their *thickness* (the electric axis) have been employed by Langevin, Boyle, and others as a *source of super-sonic vibrations*, more particularly for use under water. The same apparatus is used in the converse process of reception, for the alternating pressure of the arriving sound waves produces corresponding electrical effects which, when suitably amplified and heterodyned, can be heard in telephones. Langevin and Boyle have employed this apparatus for the detection by an echo method of submerged objects (wrecks, icebergs, etc.), the sound emitted from a large disc of quartz being sharply directional and therefore suitable for such purposes. (*See* numerous papers by R. W. Boyle in *Proc. Roy. Soc. of Canada* 1922–28.) R. W. Wood and A. L. Loomis, using a piezo-electric quartz crystal vibrating at frequencies of the order 5×10^5 cycles per second have obtained striking effects of a physical and biological nature (*Phil. Mag.*, Sept. 1927). With the crystal vibrating under oil, they estimated the pressure of the sound radiation to be equal to 150 grams weight—the free surface of the oil being raised into a mound 7 cm. high!

The uses of *Rochelle salt* as a sound generator and receiver have been demonstrated by Nicholson (*Amer. Inst. Elect. Eng. Proc.*, Nov. 1919) who in one application used the crystal to replace a gramophone sound-box, the amplified e.m.f.s produced in the crystal being sufficient to operate loud-speakers or telephones. The elasticity of Rochelle salt is very small, $E=3\times10^8$ as compared with 8×10^{11} for quartz and 2×10^{12} for steel. (An excellent bibliography on piezo-electricity and its applications is given by W. G. Cady in the *Proc. Inst. Radio Engineers*, April 1928.)

Torsional Vibrations of Rods.—A solid rod or tube of circular section may be twisted in such a way that each transverse section remains in its own plane. If the section is not circular, a warping is liable to take place and the analysis is very complex. Consider a tube of radius r and thickness δr and let θ be the angular displacement of any section distant x from the origin. The "shear" of the material of the tube is $r\cdot\partial\theta/\partial x$. The opposing elastic force per unit area is $\mu r\partial\theta/\partial x$ where μ is the coefficient of rigidity of the material ($\mu=E/2(\sigma+1)$ in which E is Young's modulus and σ is Poisson's ratio). Since the area of section of the tube is $2\pi r\delta r$ the moment of this force round the axis is $2\mu\cdot\pi r^3\cdot\delta r\cdot\partial\theta/\partial x$ and the restoring force acting on the slice of thickness δx has the moment $2\mu\pi r^3\delta r\cdot\delta x\cdot\partial^2\theta/\partial x^2$. Now the moment of inertia of the slice is $2\pi r\delta r\cdot\delta x\cdot\rho r^2$ (ρ is the density of the material) whence the equation of motion is

$$\rho\frac{\partial^2\theta}{\partial t^2}=\mu\frac{\partial^2\theta}{\partial x^2} \quad\text{or}\quad \frac{\partial^2\theta}{\partial t^2}=c^2\frac{\partial^2\theta}{\partial x^2} \quad\text{where}\quad c=\sqrt{\frac{\mu}{\rho}} \tag{24}$$

which is independent of r, and therefore equally applicable to tubes of all radii and to a solid rod. *The velocity of torsional wave transmission is* $c=\sqrt{(\mu/\rho)}$. The ratio of this velocity to the corresponding longitudinal velocity is $\sqrt{(\mu/E)}=1:\sqrt{[2(\sigma+1)]}$. Taking $\sigma=0\cdot25$ for a steel rod the ratio of velocities becomes 1·58. The possible frequencies of torsional vibration of a rod will be

$$N=\frac{s}{2l}\sqrt{\frac{\mu}{\rho}} \tag{25}$$

analogous to the harmonic series for the longitudinal vibrations. Torsional vibrations are readily set up by applying tangential forces of a frictional character, *e.g.*, by means of a resined cloth, to the free end of a rod clamped at a suitable point.

Vibrations of Membranes.—The transverse vibrations of stretched membranes are related to those of diaphragms and plates in a manner analogous to the transverse vibrations of stretched strings and elastic bars. In the former case the vibrations are conditioned by the applied tension and are independent of elastic forces, whereas in the latter the elastic forces are all-important and tension almost negligible.

By analogy with the case of wave motion in one dimension (a stretched string) it may be shown that the equation

$$m\frac{\partial^2\xi}{\partial t^2}=T\left(\frac{\partial^2\xi}{\partial x^2}+\frac{\partial^2\xi}{\partial y^2}\right) \tag{26}$$

represents the motion of a stretched, two-dimensional-membrane where T is the tension m the mass per unit area ($\rho\times$thickness) and ξ the transverse displacement at a point xy. The velocity of wave motion is $c=\sqrt{(T/m)}$ as in the case of strings. The complete mathematical analysis for stretched membranes of various shapes is given in Rayleigh and Lamb's treatises on Sound. In the case of a circular membrane of radius a the fundamental frequency is shown to be

$$N=\frac{0\cdot765}{2a}\sqrt{\frac{T}{m}}. \tag{26a}$$

In the higher partials the diaphragm becomes divided into nodal rings and diameters.

Membranes approximating to the ideal type have been made from soap films, or films of thin collodion, stretched on a metal ring, the vibrations of such thin films being examined by optical methods. Sheets of parchment or of thin metal (steel) are more suitable when it is required to examine the effects of tension. Wente's condenser microphone (*see* fig. 16a) (*see* MICROPHONE) has a highly tensioned steel membrane of fundamental frequency about 10,000 cycles per second. The various modes of vibration of a steel membrane are conveniently studied by means of a small electro-magnet (the magnet system of any ordinary telephone receiver will serve the purpose) and a valve oscillator with a suitable range of frequency-control. As a rule, the agreement between theory and observation is only approximate, for the theory generally given takes no account of the serious damping and loading of the diaphragm due to the medium (air) in contact with it. The stiffness of the membrane is not always negligible as assumed in the theory. Examples of membranes as sources of sound are to be found in various forms of drums, tamborines, etc.

[1]A. W. Pierce and J. H. Vincent have excited rods of nickel (and alloys of nickel-iron) into resonant vibration by magnetostriction.

In the drum, the vibrations of the membrane are reinforced by the vibrations of an air cavity in resonance with it.

Vibration of Diaphragms.—When elastic restoring forces are called into play and tension is of secondary importance we come to the case of the diaphragm. Rayleigh has calculated the periods and motions in vacuo, of a thin circular elastic plate rigidly clamped at the edge. By means of a complex analysis he found that the fundamental frequency of vibration is given by

$$N=\frac{2\cdot 96}{2\pi}\cdot\frac{h}{a^2}\sqrt{\frac{E}{\rho(1-\sigma^2)}} \qquad (27)$$

where h is the thickness and a the radius of the diaphragm, E Young's modulus, ρ the density and σ Poisson's ratio for the material. More recently, Lamb (*Roy. Soc. Proc.* A., Vol 98, 1920) has calculated the frequency and damping of circular diaphragms in air and in water, the value of the frequency in air agreeing closely with Rayleigh's estimate. Thus for a steel diaphragm $E=2\times 10^{12}$, $\rho=7\ 8$, $\sigma=0{\cdot}28$, whence $c=\sqrt{[E/\rho(1-\sigma^2)]}=5\ 27\times 10^5$ cms /sec , and $N=2{\cdot}5\times 10^5\cdot h/a^2$ cycles per second. If $h=0\ 1$ cm and $a=5$ cms., N will be 1,000 cycles per second in air. The *addition of a load m* to the centre of a diaphragm of mass M has the effect of lowering the frequency given by (27) in the ratio $1/\sqrt{(1+5m/M)}$.

Diaphragm Vibrating in Contact with Water or Other Medium.—The presence of an extensive medium, say water, in contact with the diaphragm has two effects, (1) the frequency is lowered on account of the loading due to the added mass of water vibrating with the diaphragm, and (2) the vibrations are damped owing to the energy radiated as sound waves into the water. Lamb has shown in the case of a diaphragm with one side only in water, that the inertia of the diaphragm is increased in the ratio $(1+\beta)$ where $\beta=0\ 6689\rho_1a/\rho h$ (ρ_1 being the density of the water, ρ the density of the material of the diaphragm, a the radius and h the thickness). The frequency given by (27) must therefore be divided by $\sqrt{(1+\beta)}$ in this case. When both sides of the diaphragm are immersed the value of β must be doubled The *persistence of the vibrations* is given by $N/k=0{\cdot}385(1+\beta)^{3/2}\rho c_1/\rho_1 c$, where c_1 is the velocity of sound in the medium and c in the material of the diaphragm Thus, in the above example where the frequency, as modified by the water, is about 550, the range over which the energy will exceed half the maximum (indicating sharpness of resonance, *see* page 8) lies between 530 and 570 p.p.s. The persistence is increased, and the resonance is sharpened, the thinner the diaphragm and the greater the load.

Diaphragms form one of the most convenient means of producing and receiving sounds in air or in water. Numerous forms of diaphragm telephone receivers and microphone transmitters are in daily use. Large diaphragms are used as sources of sound-power for signalling over large distances in air or under water. A diaphragm operated at resonance by electro-magnetic methods may become an efficient generator of sound. By suitably choosing its dimensions the frequency of the sound may have any value up to the limits of audibility. A thick diaphragm of small diameter excited by an electro-magnet provides a very convenient source of high frequency sound as an alternative to a bird call, etc , in experimental work.

Directional property of Membranes and Diaphragms.—If a membrane or a diaphragm be mounted on an annular ring it will possess definite directional properties used either as a transmitter or receiver of sound. Regarding it as a transmitter, the sound emitted from opposite sides will be of the same intensity but in exactly opposite phase. Consequently an observer "edge-on" to the diaphragm will hear nothing at all, for the sounds proceeding from opposite sides of the disc will exactly neutralize each other. In the "broadside-on" position, however, the sound from the back of the diaphragm will be partially screened by the annular ring and by the diaphragm itself, whereas the sound from the front will reach the observer unobstructed. As the transmitter is rotated through 360° therefore, the observer will hear two distinct maxima, 180° apart, separated by two corresponding minima or zero positions. The maxima will, of course, be of smaller intensity than that observed with one side of the diaphragm completely screened (in which case it is non-directional). The directional properties of an unscreened diaphragm may be simply demonstrated as a *receiver* of sound by means of a "button" granular microphone attached at the centre. The microphone gives maximum and zero response in the "broadside-on" and "edge-on" positions respectively, relative to a fixed source of sound.

Vibration of Plates.—We have already referred to the case of a quartz plate vibrating with equal amplitude and phase over its whole surface, this being treated as a special example of longitudinal vibration. We have also dealt with a circular plate clamped at the edge (*i.e.*, a circular diaphragm), the frequency of the fundamental being $0{\cdot}47hc/a^2$, and the overtones $1\ 006hc/a^2$ and $1{\cdot}827hc/a^2$ for one nodal diameter and one nodal circle respectively. When the plate is free at the edge the mathematical treatment becomes very complex. Near the edge, a peculiar state of strain exists sometimes resulting in abnormally large shearing forces on sections perpendicular to the edge. The *experimental* study of the vibrations of such plates, free at the edge and clamped at the centre of symmetry, begins with Chladni (1787). The method of producing *Chladni's figures* by bowing and touching certain points on the edge of the plate covered with fine sand, is well known. The nodal figures are very striking in their appearance and wonderful variety—nothing further is needed to testify to the complexity of the problem. Chladni preferred to use glass plates, as their transparency permits of the fingers being used to damp points underneath which are shown to be nodal by the sand above. Simple figures correspond to low frequency tones, and the more complicated figures to the higher tones. Chladni obtained 52 different figures with a square plate and 43 with a circular plate. Metal plates of moderate thickness when struck with a hammer are sometimes used as gongs The Submarine Signalling Company have used such a gong under the sea, describing it as a "disc-bell" for lifeboats.

Curved Plates, Cylinders and Bells.—The complex problem of the flat plate is still further complicated when the plate is curved—for it becomes increasingly difficult to separate the various possible modes of vibration. Rayleigh has calculated the fundamental frequency N of vibration of a thin cylindrical shell, obtaining $N\propto\frac{h}{a^2}\sqrt{\frac{e}{\rho}}$ where e is an elastic modulus involving bulk modulus and rigidity, h the thickness, a the radius, and ρ the density of the cylinder.

A bell may be regarded as a progressive development of a curved plate or, in certain forms, it may be treated as a cylindrical shell with one end closed. The possible variety of forms is far too numerous even to mention here In practically all cases the bell is supported at the centre of symmetry and is excited by striking near the free edge Rayleigh made a particular study of the vibrations of church bells, and distinguished five characteristic tones: *Lowest tone* (4 nodal meridians, no nodal circle), *second tone* (4 nodal meridians, one nodal circle), *third tone* (6 nodal meridians, sound best produced when the clapper strikes the bell on the lower thick part termed the "sound bow"), *fourth tone* (6 nodal meridians, best elicited by striking half way up), *fifth and highest tone* (8 nodal meridians). Bell founders in England recognise five chief tones in a church bell, reckoning from the *highest* they are termed the "nominal," "fifth," "tierce," "fundamental," and "hum-note." By suitable distribution of metal in the bell the founder *aims* at making the hum-note, fundamental and nominal successive octaves—but seldom succeeds. Massive bronze bells are used in charted positions, *e.g.*, lightships and buoys, under the sea as a means of signalling to ships suitably fitted with hydrophones (underwater microphones) to receive the sound. Sound travels for long distances under water and these bells can be heard many miles away, if the conditions are favourable.

Vibrations of Air Cavities.—*Columns of Air: Organ pipes* The simplest case of a vibrating mass of air in a solid enclosure

is that of a parallel cylindrical pipe the ends of which may be closed or open. The vibrations of such a column are analogous to the longitudinal vibrations of a solid rod. Provided the diameter of the pipe is not too small, so that viscous drag at the boundary is unimportant, and not too great compared with the length of the pipe and the wave-length of the sound, we can assume at any instant, the motion of particles in any particular cross section to be the same. That is, we are dealing with *plane* waves of sound in the pipe. As in the case of transverse vibrations of strings and longitudinal vibrations of rods, stationary waves are produced in the air column due to the combined effects of the direct and end-reflected waves. Thus the equation of wave motion in the pipe is $\partial^2\xi/\partial t^2 = E/\rho \cdot \partial^2\xi/\partial x^2$, indicating a wave travelling with a velocity $\sqrt{(E/\rho)}$ where E and ρ are the appropriate values of adiabatic elasticity and density of the gas contained in the pipe. Assuming a simple harmonic wave $\xi = a \cos nt$ the solution becomes $\xi = [A \cos(nx/c) + B \sin(nx/c)] \cos nt$. With the appropriate end conditions $\xi = 0$ at a node (a solid end) and $\partial\xi/\partial x = 0$ at an antinode (an open end) the various modes of vibration are readily determined.

Remembering that a pulse of compression is reflected as a rarefaction at an open end and as a compression at a closed end, it will be evident that a wave must travel twice the length of a pipe open at both ends, and four times the length of a pipe closed at one end, before the wave repeats itself, *i.e.*, in one period. If λ is the wave length and N the frequency in the stationary wave then $N = c/\lambda$. For a *pipe open at both ends* each open end must be an antinode and the length of the pipe a multiple of $\lambda/2$, that is, $l = s\lambda/2$ where $s = 1, 2, 3$, etc. We have in this case therefore a *complete* harmonic series of partials whose frequencies are given by $N = \frac{s}{2l}\sqrt{\frac{E}{\rho}}$, the corresponding wave-lengths being proportional to 1, 1/2, 1/3, 1/4, etc.

For a *pipe closed at one end* the closed end must be a node and the length of the pipe an *odd multiple of* $\lambda/4$, that is $l = s\lambda/4$ where $s = 1, 3, 5$, etc. The partials therefore form an *odd* harmonic series the frequencies being $N = \frac{s}{4l}\sqrt{\frac{E}{\rho}}$ where s is an odd integer. The corresponding wave-lengths are proportional to 1, 1/3, 1/5, etc. A closed pipe resonates to the same fundamental frequency as an open pipe of twice the length.

The position of the nodes n and antinodes a for a few of the partials of "open" and "closed" pipes are indicated in fig. 5.

Correction at Open End.—The approximate theory indicated above (due to Bernouilli) assumes an antinode at the open end.

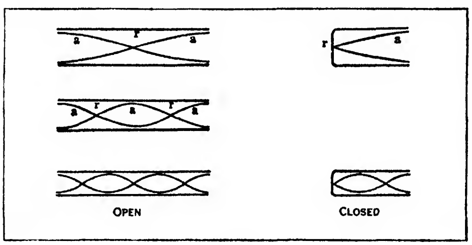

FIG. 5

A *true* antinode is a point of zero pressure-variation and maximum displacement-amplitude. At the open end of a tube the *stationary plane waves inside* are changing to *spherical progressive waves outside*. In other words, the tube radiates sound energy in all directions from the end of the tube. On account of this radiation, the intensity of the reflected waves from the open end is somewhat less than that of the incident waves, which explains the rapid damping of the vibrations when the forcing ceases. The body of air at the open end has the effect of adding inertia to the air in the tube. Consequently there is a virtual increase in the length of the air column with a corresponding lowering of pitch. Rayleigh has shown that this effective increase of length approximates to 0·6 times the radius r of the tube if the latter is unflanged. This correction applies at each open end, and is therefore $1{\cdot}2r$ for an open tube, and $0{\cdot}6r$ for a closed one. It should be observed also, as in the case of rods, that the simple theory only applies when the diameter of the tube is small relative to the length of a loop $\lambda/2$.

Resonating Liquids in Metal Tubes.—Columns of liquid enclosed in metal tubes may also be set into resonant vibration. On account of the yielding of the walls of the tube, however, the velocity $\sqrt{(E/\rho)}$ of the wave is slightly modified since the coefficient of elasticity involved is dependent on the extent of such yielding. The subject has been examined theoretically by Lamb (Sound, p. 174) and by Green (*Phil. Mag.*, 45, May 1923) who has also determined experimentally the change of velocity produced in various liquids by this yielding.

Organ Pipes.—One of the most important applications of the vibration of air columns is found in the organ pipe. This usually takes the form of a cylindrical metal tube or a wooden pipe of square section. One end of the tube is specially constructed so that a suitable blast of air will set up resonant vibrations in the column of air. In the *open "flue" organ pipe* the blast of air impinges on a thin lip which forms the upper edge of a narrow slit opening into the tube. When the blast is correctly adjusted the pipe "speaks" and the air column resonates. The fundamental tone is sounded when the blast is moderate, and by increasing the power of the blast the harmonics can successively be produced.

In another form, known as the *"reed" pipe*, the blast of air impinges on a reed which controls the amount of air entering the pipe. The reed is set in vibration and puffs of air are admitted to the pipe which resonates under the correct conditions. The reed cannot be regarded as a freely vibrating spring for it is affected by the air blast and the resonance in the pipe. "Organ" pipes have been made covering a range of frequencies 8 to 16,000 cycles per second, corresponding to lengths of 64 feet to ¼ inch respectively. Fifes, flutes, oboes, etc. are other examples of musical instruments employing resonant air columns.

Small Air Cavities: Helmholtz Resonators.—The vibrations of air cavities almost completely enclosed were first studied by Helmholtz and have considerable practical importance. A volume of enclosed air having only a small "neck" connecting with the external air radiates very little energy when set into resonant vibration. The damping is therefore very small and the tuning is very exact. The device is therefore very sensitive to a narrow range of frequencies. The motion of the air in the cavity is almost negligible compared with that in the narrow neck. Consequently we may regard the air in the neck as a piston having mass $m = \rho l S$ (ρ density, l length, and S area of neck), whilst the air in the cavity functions as a spring of "strength" $f = ES^2/v$ where E is the elasticity ($=\gamma p$) of the gas and v the volume of the cavity. The frequency N of such a mass and spring is $\sqrt{f/m}/2\pi$ *i.e.*, $N = \frac{1}{2\pi}\sqrt{\frac{ES^2}{v \cdot \rho l S}}$ or $\frac{c}{2\pi}\sqrt{\frac{S}{lv}}$ since $c = \sqrt{E/\rho}$. The ratio S/l is called the "conductivity" of the neck. For a circular aperture in a thin wall, Rayleigh shows that this quantity is equal to the diameter $(2a)$ whence $2\pi N = c\sqrt{(2a/v)}$. The frequency is independent of the shape of the cavity provided its linear dimensions are not comparable with a wave length of the sound to which it resonates. A "spherical" Helmholtz resonator is shown in fig. 6. A series of resonators of graduated frequencies (*i.e.*, of varying volume or area of mouth) may be used in the frequency analysis of complex sounds. Resonance may be detected by the ear or by means of a sensitive manometric capsule applied to the small pipe at the base of the resonator, or by means of a Tucker hot-wire microphone (*see* p. 31) placed in the mouth. Resonators of large volume, and correspondingly low frequency, fitted with hot-wire microphones were employed in the detection and location of guns during the war. (*See* SOUND RANGING.) Large resonant microphones are also used in the detection of aircraft.

Recently, E. G. Richardson (*Proc. Phys. Soc.*, May 1928) by using acoustic impedance methods, has developed a theory of vibration of air cavities which covers the extreme cases of pipes and resonant cavities, and avoids the necessity for a special open-end correction. He obtains the formula $\tan kL = \kappa/kA$ where $k = 2\pi N/c$, κ is the conductivity of the neck and A is the area of section of the cavity, assumed cylindrical. This formula leads to the recognised values of N for pipes and resonators.

Double Resonators.—In certain circumstances, where an increased sensitivity is desired, double resonators, consisting, for example, of a resonator of the closed pipe variety combined with one of the Helmholtz type, are usually employed.

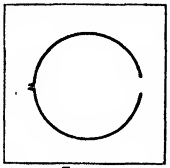

FIG. 6

By this method, which was first suggested by Boys, a large increase in amplitude may, as a rule, be obtained. The theory of such compound resonators was given by Rayleigh, and has been considerably extended recently by E. T. Paris, who uses them in conjunction with the hot-wire microphone.

Helmholtz Resonator Combined with Tuned Reed.—E. E. Fournier d'Albe has employed a sharply tuned reed (clamped free) with a small mirror attached, to indicate resonance in an air cavity. The resonant vibrations in the air cavity agitate the tuned reed, which lies across the mouth, and cause a spot of light, reflected from the mirror, to oscillate. The combination of reed and air cavity responds to one frequency only, for the overtones of the cavity do not correspond to those of the reed.

The Voice and Speech.—The *human voice* is an excellent example of a combination of vibrating reeds (the vocal cords) and resonant air cavities (the front and back parts of the mouth, separated by the tongue, and the upper or nasal cavity). The analysis and synthesis of speech sounds was commenced by Helmholtz. More recently Paget has shown that "every series of sung or spoken vowels is in fact a trio performed by three instruments, a reed and two resonators—soprano and alto—of which the soprano is in close harmonic relation with the reed." In a series of important papers (*Proc. Roy. Soc.*, 1923, 1924, 1927) Paget has analysed and synthesised the vowel and consonant sounds. Observations on breathed vowel sounds indicated that in *every* case the oral cavity as a whole, from larynx to lips, actually gives *two* simultaneous resonances for each vowel sound. In certain cases, more frequent in American "accent" a third resonance due to the upper or nasal cavity may be introduced. By means of plasticine models Paget successfully reproduced the various vowel and more important consonant sounds, as well as combinations of these in well recognised words. Crandall and Mackenzie (*Phys. Rev.*, March 1922) have determined experimentally the energy distribution in speech as a function of frequency (*See* curve fig. 7.) The maximum energy of the male voice occurs at a frequency near 120 p.p.s., the female voice having a maximum about an octave higher. In spite of the fact that the energy of the voice is mostly of low pitch it is the high pitched sounds which are essential to intelligibility of speech. The clearness of speech is unimpaired if all sounds up to 500 frequency are "filtered" out (60% of the sound energy being thereby removed). We shall see later that the *ear* is most sensitive in the region 1,000 to 4,000 frequency. The rate of emission of sound energy in conversational speech has been estimated by Sabine (*Phys. Rev.*, 21, 1923) as 125 ergs/sec and for public speech about 2,500 ergs/sec.

FIG. 7

Absorption of Sound by Resonators: Sound Filters.—A well tuned resonator absorbs energy of corresponding frequency from the sound-field in which it is placed. This absorption may extend over an area of the order λ^2/π where λ is the wave length of the incident sound ($\lambda = c/N$). Quincke (1866) employed resonators to stop tones of definite pitch from reaching the ear (*see* Rayleigh, *Sound*, vol. ii., p. 210)—the arrangement acting as a sound-filter. A complex sound passing through a pipe could have any particular tone removed, by fitting a suitable side tube to the pipe. This side tube of length l was closed by a sliding piston which served to "tune" the tube ($4l = c/N$) to any frequency N it was desired to absorb from the main pipe. Using a succession of such tuned side tubes a corresponding number of tones could be filtered out of the direct sound. G. W. Stewart (*Phys. Rev.*, 1923–26) has greatly extended the possibilities of sound filters by introducing the analogy of electrical filter circuits and the conception of acoustic impedance. On such a basis it is possible to design "acoustic circuits" functioning as "low-pass," "high-pass" and "band-filters" as in the corresponding electrical cases. The "low-pass" filter transmits only those frequencies below a certain limit, the "high-pass" above a certain limit, and the "band-pass" only within a certain range or ranges. Filters of this nature are used in the laboratory for purifying sounds, *e.g.*, removing harmonics from a complex wave-form to obtain a pure tone, and in connection with speaking devices.

Measurements of Sound Intensity; Using Air Resonators.—The amplitudes at various points in a vibrating air column or cavity may be examined qualitatively by means of small manometric capsules (fitted with tube to a sensitive flame) or by sensitive membranes carrying fine particles or small mirrors. Quantitative results have been obtained by means of a *Rayleigh disc* which, when inclined at 45° to the axis of a neck of a double resonator, forms a very sensitive detector—the disc tending to set itself at right angles to the vibrating air current in the neck of the resonator (*see* p. 14.) Alternatively *the hot-wire "microphone"* (*see* p. 31) may be used.

Kundt's Dust Figures.—To exhibit the nodes and antinodes in a resonating air column contained in a glass tube, Kundt devised the method of spreading fine powder (lycopodium seed or fine dry cork dust) along the inside of the tube. The dust is immediately thrown into a pattern indicating the positions of nodes and loops along the tube. The experiment is capable of a number of variations yielding valuable data relative to the velocity of sound in gases and solid rods. The wave length λ_g in the gas contained in the tube is at once obtained from twice the nodal separation—the wave length λ_r in the rod which excites the vibrations in the air column being, for the fundamental longitudinal vibration, equal to twice the length of the rod. These values give at once the relative velocities in the gas and the rod (*See* p. 21.)

Sirens.—The sources of sound to which we have hitherto referred are dependent on the principle of resonance for their efficient action. We shall now deal briefly with an entirely different type of sound generator. In the earliest form of siren a revolving disc perforated with a ring of equally spaced holes interrupted a jet of air from the nozzle of a tube mounted opposite the ring of holes. The fundamental frequency of the note produced by the successive puffs of air emerging beyond the disc is clearly equal to the product of the number of holes and the revolutions per second of the disc. This primitive form is known as *Seebeck's Siren* (1805–1849). In later forms of siren (C. de la Tour's form) the holes were drilled obliquely to the surface of the disc so that the blast of air also produced the necessary rotation of the disc. In this form the intensity of the note increased with frequency—the sound amplitude being roughly proportional to the pressure of the air supply. In recent laboratory forms the siren is motor driven, means being provided for indicating the speed of the revolving disc and consequently the frequency of the sound. A motor driven siren forms a very

convenient means of determining, by a direct method, the pitch of a note. With a circular nozzle and equal circular holes the siren note is generally impure—containing a plentiful supply of harmonics in addition to the fundamental. Milne and Fowler (*Roy. Soc.*, *98*, 414, 1921) describe a special form of siren which gives comparatively pure tones. The holes in the rotating disc are specially shaped so that the uncovered area of the nozzle varies sinusoidally.

Dove and Helmholtz produced sirens having several rings of holes provided with corresponding nozzles, so that one or more tones could be produced simultaneously. Sirens driven by compressed air or steam are in common use as sources of sound. Similar devices modified to suit the special conditions have been used for signalling under water—the air supply of the ordinary siren being replaced in this case by a jet of water which causes rotation of the disc and gives the necessary vibratory impulses to the surrounding water.

The Diaphone, a powerful long range signalling device for use in air, is essentially a siren of the same group as those of Seebeck and La Tour since it differs from them only in the fact that the opening and closing of the ports is effected by a reciprocating instead of a rotary motion—this reciprocation being produced directly by means of the compressed air supply.

The Centrifugal Siren.—This device consists of a radially-vaned cylindrical rotor revolving in a stationary casing in which ports are cut. The vanes are connected in pairs at their outer edges by cylindrical segments, so that rotation causes opening and closing of the fixed ports. Air is drawn through an axial aperture where the vanes are cut away. The sound is produced by the expulsion of air through the ports by the centrifugal action of the rotor which may be driven by an electric motor or internal combustion engine. Sirens of this type constitute very powerful and efficient sources of sound for long distance transmission in air, *e.g.*, for use on light-vessels or shore stations as a means of signalling to ships at night or in foggy weather.

Sounds Produced by Rotating Propellers.—The hum of an electric fan which increases in pitch with increase of speed can be heard only at a short distance. The noise produced by the propeller (airscrew) of an aeroplane may, under favourable conditions, be heard several miles away. The sound emitted in both these cases arises, in the absence of excessive vibration, from the rotation of the "source and sink system" associated with the pressure differences on the rotating blades. A. Fage (*Roy. Soc. Proc.*, *107*, 1925) has analysed the sounds emitted from various types of airscrews by means of a resonator, of continuously variable tuning, fitted with a Tucker hot wire microphone. He found that the sound of rotation consists of a large number of harmonics having as fundamental a note of frequency equal to the product of the number of blades and the rotational speed. In addition to these sounds, "tearing sounds" associated with the shedding of eddies from the blades were also observed but the frequencies were not determined. Sounds arising from the flexural vibrations of the airscrew blades and the shaft were found to have frequencies in agreement with calculation.

Propellers Under Water.—Most of the under-water noise from a moving ship comes from the screw propeller. As it revolves, "cavitations" are formed just behind the blades. When these cavitations collapse either on themselves or on the blades, a noise is produced. This noise has no predominant frequency, although it is to some extent characterised by the beat of the engines or the rush of the turbines which drive the propeller. If the latter revolves slowly the cavitations are not formed and there is very little noise. With suitable receivers (hydrophones) the noise of a ship proceeding at a moderate speed, say 10 or 15 knots, can be heard several miles away. (*See* Bragg, *World of Sound.*)

Explosive Sounds.—The ejection of a shell from a gun and the subsequent explosion of the shell are both accompanied by a pressure-wave of large amplitude which can be detected at long ranges. This pressure-wave has, however, a different character in the two cases—the explosion at the gun is due to the ignition of cordite which burns relatively slowly when compared with the rate of detonation of the T.N.T. in the shell. Consequently the gun-wave has a wave-front which is much less abrupt than that of the shell detonation. This appears to the ear as the difference between a "boom" and a "crack." An observer of such pressure waves at a distant point receives what appears to be a continuous train of waves, *i.e.*, a reverberation effect, due to the numerous reflected pulses from objects along the track of the primary pulse. Such reverberations may last several seconds. Similar effects are observed under water on the explosion of a mine or a depth charge. The explosion of a few ounces of guncotton under water can be detected and recorded 30 or 40 miles away. A rapid succession of explosions at equal intervals of time may result in a noise of a more or less musical character. This is exemplified in high speed gas or petrol engines, particularly those with several cylinders operating in succession. The note is harsh and the fundamental is accompanied by a long train of harmonics. The musical noise of a high frequency Wehnelt electrolytic interrupter (used in X-ray work) is also due to a regular succession of explosive impulses, arising from the sudden generation of gas under the liquid. The wave-form of such a series of impulses recorded on a cathode-ray oscillograph indicates the extremely abrupt nature of detonations. A single impulse is often sufficient to set a resonator into vibration, thereby producing, indirectly, a musical note.

A single impulse of an explosive nature, produced by a powerful electric spark has been employed in the study of the progress of a sound-wave under controlled conditions—particularly in connection with the complex reflections of sound-waves in auditoriums. (*See* ACOUSTICS OF BUILDINGS.)

Sounds Maintained by Heat.—Most bodies on being heated will expand and in so doing perform a certain amount of mechanical work. If the phases of the forces thus called into play are favourable, a vibration may be set up and maintained.

Trevelyan's rocker is a good example of such a maintained vibration. It consists of a prism of brass or copper almost triangular in section with one edge grooved to form two adjacent parallel ridges. The prism rests with its groove downwards on a block of lead with a rounded top, the end of the prism terminating in a ball which rests on a smooth surface. When the prism is heated and placed on the lead block it begins to vibrate, the weight being carried alternately on one or the other of the two ridges. The cause of these vibrations was ascribed by Leslie to the expansion of the cold block at the point of contact with the hot metal. The effect can be obtained also by a local heating of the points of contact by means of an electric current.

Singing Flames.—Under certain circumstances a small gas flame inserted into a resonant chamber of air or other gas, will emit a musical sound. If heat be given to the air in a vibrating column at the instant of greatest condensation the vibration will be encouraged. If the phase of the heat supply be reversed the vibration will be discouraged. An essential feature of the maintenance of the vibration is the presence of stationary waves in the gas supply tube as well as in the singing tube. The jet must be a node to correspond with a node in the singing tube where the maximum pressure-amplitude occurs. For most satisfactory operation therefore it is necessary (a) that the gas jet should be at or near a node in the singing tube and (b) that the length of the gas supply tube should be an odd multiple of $\lambda/4$ (where λ is the wave-length, *in the gas*, of the note sounded). The tube will not sing at all if the length of the supply tube lies between $\lambda/4$ and $\lambda/2$, $3\lambda/4$ and λ, and so on. Spherical resonators, large globes, may also be employed, and bulbous chimneys as used for paraffin lamps give satisfactory results. The intermittent character of a singing flame is easily demonstrated by means of a revolving mirror, from which it appears that at one phase the flame may withdraw itself entirely within the gas supply tube. The vibrations sometimes reach sufficient intensity to extinguish the flame completely. For a complete discussion of the phenomena of singing flames Rayleigh's *Sound*, vol. ii., p. 224, should be consulted.

Gauze Tones.—Rijke in 1859 made the discovery that a sound of considerable power may be produced by a heated piece of fine metal gauze stretched across the lower part of a vertical open tube containing air. In the earlier experiments the gauze was heated by a gas flame and the sound was observed immediately *after* the removal of the flame. Keeping the gauze hot by means of an electric current the sound may be maintained indefinitely. The maintenance depends on the variable transfer of heat due to the motion of air through the gauze, this motion being a uniform upward convection current with a superposed alternating motion due to the resonant vibration of the air in the tube. In the lower half of the tube the alternating flow assists the direct flow a quarter period *before* the phase of greatest condensation and opposes it a quarter period *after* this phase. Bosscha and Reiss (1859) demonstrated the complementary phenomenon. If a current of *hot* air fall on a *cold* gauze, sound is produced—in this case the phase relationship requires the gauze to be in the *upper* half of the tube, preferably about a quarter the length of the tube from the top.

The Thermophone. Fine Wires or Strips Heated by Alternating Currents.—When an alternating current $i\sin nt$ is passed through a fine wire of resistance R the heat developed is proportional to $Ri^2\sin^2 nt=\frac{1}{2}Ri^2(1-\cos 2nt)$. Consequently the heat developed will vary between 0 and $\frac{1}{2}Ri^2$ at a frequency $2n/2\pi$, that is, at twice the frequency of the current. If a sufficiently large initial direct current i_0 be passed through the wire the double frequency term in $R(i_0+i\sin nt)^2$ or $\{R(i_0^2+\frac{1}{2}i^2)+2Ri_0i\sin nt-\frac{1}{2}Ri^2\cos 2nt\}$ may be made negligible—the fluctuations of heating effect then vary with the frequency $n/2\pi$ of the current.

Using very fine platinum wires (10^{-4}cm. thick), P. de Lange (*Roy. Soc. Proc.*, 91, Ap. 1, 1915) demonstrated that the decrease and increase of heat took place synchronously with the A.C. supply. The air surrounding the wire was thereby rapidly heated and cooled, the corresponding expansions and contractions appearing as sound. Ordinary telephonic currents, of speech frequency, were shown to be sufficient to produce easily audible sounds in a small earpiece containing the fine wire heater and a small volume of air. This device is known as a *Thermophone.* The reproduction is of good quality, but somewhat feeble relative to the response of electro-magnet telephone receivers. Provided the frequency is not too high, the thermophone has a possible application as a metrical source of sound.

Directional Sources of Sound.—It is evident that a greater range of transmission will result if a given amount of sound energy is confined to a cone with a small angle of divergence instead of spreading uniformly in all directions. Other advantages of a directional transmitter will be equally apparent. Certain sources of sound exhibit inherent "directional" properties, due to the fact that their dimensions are considerably greater than a wave length of the sound they emit. Other sources may show no inherent directional property but may be made directional by the use of some attachment such as a trumpet or a mirror. A line or an area of equally spaced non-directional sources vibrating in phase may act as a directional compound source

Sources of Large Area The linear dimensions not small compared with a wave-length. Rayleigh (vol. ii., p. 138) refers to the directional properties of a speaking trumpet when used to transmit high pitched sounds, such as a whisper or a hiss. An instructive example of this nature is the case of radiation of high frequency sound waves from one face of a quartz piezo-electric "piston" oscillating with uniform amplitude and phase at all points of its surface (*see* R. W. Boyle, *Proc. Roy. Soc.* Canada, III, 1925, p. 167). The sound-distribution round such a source is analogous to that of plane waves of monochromatic light falling on an aperture and forming a diffraction pattern beyond. Consider the case of a circular piston source of radius a radiating waves of length λ ($\lambda=c/N$ where c is the velocity of sound in the medium and N the frequency of vibration). As in the optical case, the sound is a maximum along the axis of the piston where all the elementary disturbances from the various points of the piston arrive in the same phase. In directions inclined to the axis the intensity is less, diminishing steadily to a minimum when the difference in distance to the nearest and the furthest points of the piston is rather more than half a wave-length. In this case, the effect of the further portion of the disc is just neutralised by the effect of the nearer portion. In directions still more inclined, the sound increases again to an intensity equal to 0·017 of that along the axis. This is succeeded by another minimum value and further maxima of small intensity—corresponding to the various diffraction rings in the optical analogue. The angle α at which the first silence occurs is $\sin^{-1}(0{\cdot}610\lambda/R)$. Thus *the central "beam" of sound will be confined to a cone of small angle when the radius R of the piston is many times the wave-length.* The polar distribution of amplitude is somewhat similar to that shown in figure 8 for a line of small nondirectional sources. When the radius R does not exceed $\lambda/4$ the elementary disturbances from the piston combine without much opposition in phase, and the intensity is nearly the same in all directions—the case of a non-directional source of sound.

Rayleigh obtained general verification of this theory by means of a speaking trumpet and high pitched sounds—a considerable concentration of sound on the axis being obtained. Boyle, using a Langevin type of piezo-electric quartz disc (*see* p. 12) showed that the sound distribution (the polar diagram) in water was in good agreement with theory. In one example $R=7{\cdot}65$ cm., $N=135{,}000$ p p sec, $c=1{\cdot}5\times10^5$ cm/sec. for water, $\lambda=1{\cdot}11$ cms. whence $\alpha=5^\circ$ approximately. This angle was verified experimentally. The application of such a high frequency directional sound beam has already been mentioned.

Double Sources.—The "piston" radiator to which we have referred is a *single source of sound*—it radiates from one face only, the anterior face being suitably screened. A vibrating diaphragm mounted on a ring radiates from *both* faces, the radiation from one face being at any instant in opposite phase to that from the other face. Such a vibrator is described as a *double source.* As we have seen (*see* p. 13) a double source, such as a diaphragm on a ring, situated in an open space, air or water, is inaudible from any point in its equatorial plane, maximum sound being received at right angles to this plane

Nondirectional Source Used with Mirrors, Trumpets, Zone Plates, etc.—As in the case of piston sources of large area, a "directed" source, employing for example a mirror or a trumpet, can exhibit good directional properties only if the dimensions of the mirror, etc, are not small compared with the wave-length of the sound. This condition involves bulky apparatus if the wave-length is appreciable, the alternative being the use of high frequency sounds of short wave-length. If the beam is to be narrow, it is also desirable that the area of the source at the focus of a mirror for example should not be large. This involves a further difficulty when a large sound-output is required, for the source must then have a very large amplitude, a condition which leads to inefficient transmission both in air and in water. In air, serious degradation of energy may take place at large amplitudes (*see* Hart, *Roy. Soc. Proc*, A. 105, 1924, p. 80) and in water "cavitation" troubles arise (*see* Boyle, *Roy Soc. Proc.*, Canada, III, 1922, p. 157). The use of mirrors, trumpets, zone plates, etc, are consequently more suited to the directional *reception* of high frequency sounds—where such troubles do not arise. Concave mirrors of say 1 to 2 feet diameter and 6 to 12 inches focal length are fairly efficient reflectors of high pitched sounds like a watch tick or the notes from a Galton's whistle.

Multiple Sources.—As in the case of a large piston vibrator, a line of small "point," sources, suitably arranged, will have definite directional properties. Suppose we have "m" equidistant sources in a straight line vibrating with the same phase, amplitude, and frequency. We require to know the polar distribution of amplitude in any plane passing through the line of m sources. (*See* fig. 8a.) It is readily proved that the resultant amplitude r at a distant point P is given by

$$r=\frac{\sin(m\pi d/\lambda\cdot\cos\alpha)}{m\sin(\pi d/\lambda\cdot\cos\alpha)}$$

if d is the spacing-distance of the sources each of amplitude $1/m$, and α is the orientation of the point P with respect to the line source. An important case arises when $d=\lambda/2$, *i.e.*, when the sources are spaced half a wave-length apart. Then

$$r=\sin(\pi/2\cdot m\cos\alpha)/m\sin\left(\frac{\pi}{2}\cdot\cos\alpha\right).$$

This is zero whenever $\sin(\pi/2\cdot m\cos\alpha)$ is zero, *i.e.*, whenever $\cos\alpha\cdot m/2$ is an integer. Suppose, for example there are 6 sources spaced $\lambda/2$ apart, then $m\cdot\cos\alpha\cdot/2$ may be 1, 2, or 3, whence $\alpha=70°\ 48'$, $48°\ 42'$ and $0°$ giving the directions OP of zero amplitude. The primary maximum occurs when $\alpha=90°$ and secondary maxima at $\alpha=60°$ and $30°$ approx. The polar distribution from 0 to π is shown in fig. 8b the value of r being plotted radially from O in the direction α. This distribution is the same in all planes which include the line of sources. When d has other values, the polar distribution includes secondary maxima which may approach the primary in magnitude (*see* paper by H. Stenzel, *Eleektrische Nachrichten Technik*, Band 4, Heft 6, 1927, pp. 239–253). It will be seen that a vertical line of sources spaced $\lambda/2$ apart will give a definite concentration of energy in a horizontal plane at right angles to the line of sources. Such a concentration is, for example, of considerable importance in a fog signalling device, where a maximum energy concentration is required in a horizontal plane surrounding a light-vessel. It may similarly be shown that a number of equidistant sources arranged on a circle and vibrating in phase will give a primary maximum of intensity on the axis, with a number of zero and secondary maxima positions as in the case of a disc.

Aeolian Tones.—The "singing" of telegraph wires and the "whistling" of the wind through tall grass and trees are very familiar sounds. The "thrumming" of a tightly stretched wire in a stream of water is evidently due to a similar cause. Aeolian tones are produced when wind rushes past a stretched wire, their excitation depending on the formation of unstable vortex sheets. When wind of sufficient velocity passes a wire, a double series of vortices are set up immediately behind it, one set revolving in the opposite direction to the other and the flow of air past the wire wavers from side to side. In this manner vibrations are set up in the surrounding air which, under the right conditions, will be audible. Strouhal investigated the effect by revolving a vertical stretched wire about a parallel axis. He found that the frequency was expressed by $N=0{\cdot}185\ v/d$ where v is the velocity and d the diameter of the wire. When the speed is such that N corresponds with one of the natural frequencies of the wire the sound is greatly increased. Rayleigh showed that the vibrations of the wire are transverse to the direction of the wind. This is readily explained on the vortex theory; the oscillations of air flow behind the wire reacting on the wire itself. The Aeolian harp consists of a number of wires, all of the same low pitch but of different thicknesses stretched on a sounding-board and exposed to the wind. The varying thicknesses of the strings results in a series of different notes.

Noises in General.—In addition to the various sources of sound to which we have referred there are innumerable others. Almost every material object in motion is a source of sound vibration. In all parts of the world there has been a steady increase in traffic noise during recent years, the problem of the reduction of such noise becoming increasingly acute. Relative motion and intermittent contact between solid bodies, such as a vehicle on a road, results in a shock excitation of the numerous resonant vibrations which are possible in a complex structure. A heavy vehicle fitted with solid tyres and having many loose parts is an irritating example of this when it runs over a somewhat irregular road surface. The complex noise issuing from such a vehicle may be analysed into the simpler forms which we have considered above. The prevention of such noises involves many considerations, but obvious improvements may be obtained by (1) use of pneumatic tyres, (2) tightening of all loose "rattling" contacts, (3) balancing of all parts of machinery in rapid motion, (4) use of oil to reduce frictional noises, (5) use of pressure reducers or "silencers" for exhaust gases, etc.

The noise of breaking waves or rushing water may be ascribed to the resonant vibrations of air cavities enclosed momentarily by the water.

TRANSMISSION OF SOUND

It is important now to consider what takes place in an extended elastic medium (solid, liquid or gas) containing a source of sound. *Sound waves* are the inevitable result when vibratory stresses are set up by any means at any point of an elastic medium. Such sound waves consist of alternations of condensation and rarefaction, corresponding to the successive forward and backward movements of the source. The state of compression is passed on from layer to layer of the medium, with the velocity of sound; this being followed in turn by a rarefaction, another compression, and so on, as long as the source continues to vibrate. The phenomena of propagation of such waves of condensation and rarefaction may be demonstrated very simply by means of a long helical spring supported at suitable intervals by thin threads. Simple harmonic longitudinal displacement of one end of such a spring results in the generation of waves which travel along the spring at a definite speed. In such waves, *as in sound-waves, the displacements of individual particles are in the direction of propagation of the wave*—the motion is consequently termed *longitudinal*, as distinct from transverse wave motion in which the displacements are at right angles to the direction in which the wave travels (*e.g.*, ripples on water, or waves travelling along a stretched string). If the condensational wave travels with a uniform velocity c cms./sec and the source of sound has a frequency of N periods per second, it will be clear, without formal proof, that there are N condensation and N rarefactions in the distance c covered by the wave in one second. Now the distance, by which one condensation is ahead of the next, is called the *wave-length* λ *of the sound* in the medium; consequently we have $N\lambda=c$. When a simple harmonic vibration is transmitted through the medium the linear density of the particles, or their state of compression or expansion, is at any instant represented by a simple harmonic curve which repeats itself at regular intervals of a wave-length.

Plane Waves.—The problem in its simplest form is that of transmission of a plane (or non-spreading) simple harmonic wave *in a positive direction* along the axis of x. The particle displacement ξ at any time t of a point whose mean position is x will be given by

$$\xi=a\sin 2\pi(t/\tau-x/\lambda) \qquad (1)$$

or

$$\xi=a\sin 2\pi(Nt-x/\lambda) \qquad (2)$$

where a is the amplitude, τ and N the period and frequency and λ the wave-length of the vibration. Writing $c=N\lambda=\lambda/\tau$ we obtain other forms of these equations, viz.,

$$\xi=a\sin[2\pi/\lambda\cdot(ct-x)] \qquad (3)$$

and

$$\xi=a\sin n(t-x/c) \qquad (4)$$

where n has the usual significance and is equal to $2\pi N$. These four alternative expressions for the particle displacement ξ in a progressive plane wave are convenient for most purposes. Comparison of these relations shows that the phases, in the case of progressive waves, may be expressed in terms of fractions of a wave length λ which corresponds to a phase-angle of 2π. Thus the difference of phase between the vibrations of two particles at x_1 and x_2 respectively from the origin will be $2\pi\ (x_2-x_1)/\lambda$. It will be evident that a system of *waves travelling in the negative direction* of x will be represented by the introduction of a positive instead of a negative sign inside the brackets in the above expressions for ξ. A system of simple harmonic progressive waves may, of course, be represented graphically with the displacement ξ plotted as ordinates and the time t as abscissae.

Velocity and Acceleration of Particles in the Wave.—Differentiating ξ with respect to t we obtain the particle velocity, thus

$$\partial\xi/\partial t=na\cos n(t-x/c) \quad\text{or}\quad \partial\xi/\partial t=-c\partial\xi/\partial x. \qquad (5)$$

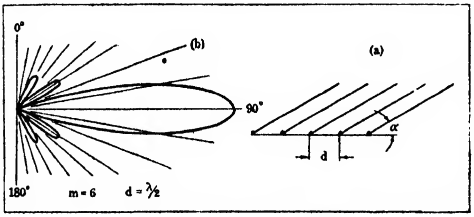
Differentiating again, we obtain the acceleration

$$\partial^2\xi/\partial t^2=-n^2a\sin n(t-x/c) \quad\text{or}\quad \partial^2\xi/\partial t^2=c^2\partial^2\xi/\partial x^2. \qquad (6)$$

Relations (5) and (6) give the particle velocity and acceleration in terms of wave velocity c and the slope and curvature of the displacement curve. Equation (6) is the differential equation which characterises wave motion Its complete solution is

$$\xi = f(ct-x) + F(ct+x) \qquad (6a)$$

which represents two independent systems of waves travelling in opposite directions with the same velocity c. *This velocity is*, within



FROM STENZEL IN "ELECKTRISCHE NACHRICHTEN TECHNIK" (WEIDMANN)

FIG. 8

certain limits entirely independent of the form of the wave, being *independent of wave-length* λ *and amplitude* a Within these limits, *the velocity is determined solely by the physical properties of the medium.* As we shall see, these properties are density and elasticity, corresponding to the factors mass and stiffness in the case of the vibrations of a particle As the wave travels through the medium the volume and density fluctuate locally, these fluctuations being controlled by the properties of the medium and the applied forces The following definitions are important:—

Dilatation Δ is the ratio of the increment of volume δv to the original volume v_o, thus

$$\Delta = \partial v / v_o \quad \text{and} \quad v = v_o(1+\Delta). \qquad (7)$$

Condensation s is the ratio of increment of the density $\partial\rho$ to the original density ρ_o thus

$$s = \partial\rho/\rho_o \quad \text{and} \quad \rho = \rho_o(1+s) \qquad (8)$$

since $\quad \rho v = \rho_o v_o \quad \text{and} \quad (1+s)(1+\Delta) = 1 \qquad (8a)$

and $s = -\Delta$ neglecting $s\Delta$ as a small second order quantity

Volume or Cubic Elasticity κ sometimes known as "bulk modulus" of elasticity.

$$\kappa = \delta p/\delta v/v_o = -v_o\delta p/\delta v = \delta p/s \qquad (9)$$

where δp is the stress and δv the strain, whence we have, for small variations of s,

$$p = p_o + \kappa s \qquad (10)$$

Compressibility C is the reciprocal of κ. Thus

$$C = -1/v_o \cdot \delta v/\delta p = 1/\kappa \qquad (11)$$

In the case of plane-waves travelling along the axis of x, the displacements of planes normally at x and $x+\delta x$ will, at a time t, be ξ and $\xi+\delta x\cdot\partial\xi/\partial x$ respectively. The thickness of the layer bounded by the two planes is therefore changed from δx to $(1+\partial\xi/\partial x)\delta x$. Consequently the dilatation $\Delta = \partial\xi/\partial x = -s$. The mass of unit area of the layer is $\rho_o\delta x$. If the excess pressure on the $(x+\delta x)$ face is δp we may equate this force to the product of the acceleration and the mass of the layer, thus $\rho_o\delta x\cdot\partial^2\xi/\partial t^2 = -\delta p$ or $\partial^2\xi/\partial t^2 = -\delta p/\rho_o\delta x$ Now $\delta p = \kappa s$ from (10), and $s = -\partial\xi/\partial x$,

therefore $\quad \partial^2\xi/\partial t^2 = \kappa/\rho_o\cdot\partial^2\xi/\partial x^2 \qquad (12)$

or writing $\quad c = \sqrt{(\kappa/\rho_o)} \qquad (13)$

$$\frac{\partial^2\xi}{\partial t^2} = c^2\frac{\partial^2\xi}{\partial x^2} \qquad (14)$$

which is equation (6) above, the complete solution being given in (6a). *The velocity of plane-waves in the medium is therefore equal to* $\sqrt{(\kappa/\rho)}$. The above method of treatment applies to all cases of transmission of small amplitude plane-waves in solid, liquid, or gas, provided the appropriate modulus of elasticity is used. The bulk modulus κ is applicable only to large masses of fluid, where change of volume but not change of shape can take place For a solid in bulk κ must be replaced by $(\kappa+\frac{4}{3}\mu)$ where μ is the rigidity whilst for a solid rod Young's modulus E is the appropriate elastic constant

Kinetic Energy in Plane-Waves. Intensity —The rate of transfer of energy per unit area of cross section of the wave may be regarded as a physical measure of the intensity of the sound transmitted The kinetic energy of a layer of unit area and thickness δx is $\delta E = \frac{1}{2}\rho_o\,\delta x(\partial\xi/\partial t)^2$ The maximum value of $\partial\xi/\partial t$ is na (from eqn [5]). Consequently the maximum kinetic energy per unit area and unit length (*i e* unit volume) of the wave $= \frac{1}{2}\rho_o n^2a^2$— (15) Since the sum of kinetic and potential energies is a constant, $\frac{1}{2}\rho_o n^2a^2$ *must also be the total energy of the wave motion per unit volume.* This quantity may be described as the *energy density* in the wave Now the wave travels a distance c per second, therefore the *transmission of energy per second per unit area of wave-front* $= \frac{1}{2}\cdot\rho n^2a^2c$ (16). This may be regarded as a measure of *the intensity of the sound-wave.* The intensity is therefore equal to the product of energy density $(\frac{1}{2}\cdot\rho n^2a^2)$ and wave velocity c. The *maximum particle velocity* $\partial\xi/\partial t$ is from (5) equal to na and the *maximum condensation*

$$s = -\partial\xi/\partial x_{\text{max.}} = na/c,$$

that is, equal to the maximum particle velocity divided by the wave velocity The expression for the intensity may therefore be written $= \frac{1}{2}\,\rho c^3 s^2_{\text{max.}}$ Now

$$c^2 = \kappa/\rho \quad \text{and} \quad \delta p_{\text{max.}} = \kappa s_{\text{max.}}$$

therefore the *intensity or energy flow/sec.* $= (\delta p_{\text{max}})^2/2\rho c \quad (17)$ a useful expression giving the intensity of the sound-wave in terms of maximum pressure variation in the path of the wave

Power of Sound Source. Radiation Impedance.—The energy thus present in the sound-wave must be derived from the vibrating source The rate at which the source does work, that is the power of the source, in producing sound-waves, is equal to the product of pressure variation and particle velocity, *i e.*, to $\delta p\times\partial\xi/\partial t$ per unit area of wave-front. Now

$$\delta p = \kappa s = \kappa/c\;\partial\xi/\partial t, \quad \text{and} \quad c = \sqrt{\kappa/\rho}$$

whence $\quad \delta p = \sqrt{\kappa\rho}\;\partial\xi/\partial t. \qquad (18)$

Therefore the power expended by the source per unit area of wave-front $= \sqrt{(\kappa\rho)}\cdot(\partial\xi/\partial t)^2$ (19). The relations expressed in (18) and (19) are closely analogous to the relations between e m f, current, and resistance in electrical circuits If we regard δp, $\sqrt{\kappa\rho}$, and $\partial\xi/\partial t$ as corresponding to e m f E, resistance (or impedance) R, and current i respectively we see that eqn (18) is the mechanical analogue of Ohm's law in electricity, and that (19) is analogous to power dissipation Ri^2 in an electrical circuit. The quantity $\sqrt{\kappa\rho}$ or ρc is consequently designated the *radiation impedance* per unit area of the medium transmitting the sound-wave This quantity is important in the consideration of the transmission of sound waves through a succession of different media (*see* p. 18).

Spherical-Waves.—The results derived above for the energy in plane-waves hold equally well for spherical-waves at a sufficient distance from the source. Elementary considerations at once indicate that the energy density in the wave will vary inversely as the square of the distance from a point source of spherical-waves, whence it may be inferred that the amplitude (of displacement, pressure or condensation) will vary inversely as the distance. This assumes, of course, that the amplitudes are small at all parts of the wave, and that there is no loss of energy due to viscosity, heat conduction and similar causes.

As in the case of plane-waves, it may be shown that the *intensity* at a point in the wave is given by $(\delta p_{\text{max.}})^2/2\rho c$.

Single and Double Sources. Energy Emission from Solid Vibrators.—A simple point source is a theoretical abstraction, but in practical cases where the source is a vibrating surface of appreciable area, each *element* of this area may be regarded as a

simple source of spherical-waves, and the effect of the source as a whole obtained by integrating the effects of the elementary areas. Again, many vibrating bodies are not *simple sources.* For example a diaphragm radiating sound to air on *both* sides is, at any particular instant, sending out a compression pulse on one side and a rarefaction pulse on the other—thus behaving like two sources near together and in opposite phase; in other words acting like a *double source.* The prongs of a tuning fork each act as double sources in a similar way. Lamb (*Dynamical Theory of Sound*) shows that *the rate of energy emission, or power, of a simple source is equal to* $\rho n^2A^2/8\pi c$, where ρ and c are the density and velocity of sound in the surrounding medium, $n/2\pi$ is the frequency, and A is the "strength" of the source (*i.e.*, the maximum rate of emission of fluid at the source); *the power of a double source is equal to* $\rho n^4B^2/24\pi c^3$, B being the "strength" of the double source. In both cases it will be seen that the rate of energy emission increases rapidly with increasing frequency. For the same strength and frequency, the energy emitted in different media will vary directly as the density and inversely as the wave-velocity (or the cube in the case of a double source). In gaseous media, where the velocity varies inversely as $\sqrt{\rho}$, the energy emission at constant frequency will vary inversely as (wave-velocity)^3 and (wave-velocity)^5 respectively in the two cases. These deductions account for the apparent feebleness of a bell or a tuning fork when vibrating in hydrogen as compared with air. The wave-velocity in hydrogen is 3·9 times that in air, therefore the energy emission from the same strength of source will be $(3{\cdot}9)^5$ or 900 times as great in air as in hydrogen. Another example:—the relative densities and wave-velocities for air and water are $1/770$ and $1/4{\cdot}4$ respectively—the energy emission, on these grounds, being, for sources of the same strength and frequency, about 3,400 times as great in water as in air. The loading effect of the water and the limitations of output of sound generators must also be considered in dealing with actual cases. The quantities A and B in the above relations, denoting "strength" of source involve the area and form of the vibrating surface, amplitude and frequency. There is consequently for the same amplitude and frequency an increased rate of energy emission with increase of area in contact with the medium—exemplified by the increase of sound emitted when a tuning fork is brought into contact with a sounding board like the top of a table. The sounding board of a piano or a violin radiates practically all the vibrational energy of the strings, the damping of the latter being increased accordingly.

In designing "sound generators" it is important to observe that the sound energy radiated bears a definite relation to the total energy available at the source. The conditions governing efficiency in this connection are similar to the analogous case of an electrical generator supplying power to an external circuit.

"*Local Flow.*"—When the vibrations of a solid body immersed in a fluid medium are very slow, the fluid behaves as if it were incompressible and simply flows locally from one surface of the "double source" to the other surface in opposite phase. In that case no sensible vibration is transmitted through the medium. As the vibrations increase in frequency the local flow is reduced, whilst true alternating pressure-waves, *i.e.*, sound-waves, are set up in the medium. Again, at constant frequency, the higher the velocity of sound in the medium, the more nearly does the medium approach incompressibility, consequently the local flow is greater and less energy is radiated as sound.

On all grounds it is clearly preferable to use the *simple source* rather than the double source type of sound generator, for the local flow is reduced and there is no neutralising effect due to "out of phase vibrations" from a neighbouring surface. The increase of sound radiated from a tuning fork when "local flow" is reduced, may easily be demonstrated (*see* fig. 9). A piece of cardboard is held with one edge parallel and close to a prong of the vibrating fork. In positions A and B no effect is produced, whereas at C the sound is considerably increased in intensity.

The Principle of Superposition.—Huyghens first drew attention to the fact that the passage of one beam of light through an aperture is in no way affected by the passage of another beam through the same aperture. It is a commonplace observation that any number of sound-waves may cross the same air space at the same time without the slightest evidence of confusion due to overlapping. This independence of the separate waves is explained by the principle of superposition, according to which the resultant effect of a number of displacements may be obtained by vector addition. The validity of this important principle is dependent on the assumption that the elastic properties of the medium are such that the stresses are linear functions of the strains—a condition which is fulfilled in the case of small-amplitude sound-waves.

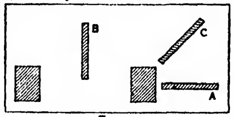


FIG. 9

Huyghens' Secondary Waves.—Another important principle due to Huyghens is the following:—The wave-front of a disturbance may at any instant be obtained as the envelope of the secondary waves proceeding from all points of the wave-front at some preceding instant. Thus the disturbance diverging from a point source may at any time t be regarded as represented by a thin spherical shell of radius ct, each point of which now serves as the origin of further spherical disturbances, the envelope of which becomes the new wave-front.

VELOCITY OF SOUND

It has already been shown that the velocity of sound-waves of small amplitude in an unlimited fluid medium is given by $\sqrt{(\kappa/\rho)}$ where κ is the bulk modulus of elasticity and ρ the density of the medium. In the case of a solid in bulk, κ must be replaced by $(\kappa+\frac{4}{3}\mu)$ where μ is the rigidity of the solid. In special cases where the volume of material is limited, *e.g.*, in solid bars or columns of liquid in tubes, it is important that the appropriate elastic constant be chosen.

In Gases.—When a gas is compressed it is heated, and when rarefied it is cooled. If the heating or cooling effects are not neutralised by removal or supply of heat, *e.g.*, by convection, then the temperature of the gas will rise or fall accordingly. In ordinary sound-waves the alternate condensations and rarefactions take place so rapidly that there is no time for a transfer of heat between adjacent layers of gas. Consequently the temperature rises and falls with the same frequency as the waves of pressure. Such conditions are described thermodynamically as adiabatic. In an adiabatic compression, the relation between pressure p and density ρ of the gas is $p/\rho^\gamma=$constant, that is $p/p_o=(\rho/\rho_o)^\gamma$ where $p_o\,\rho_o$ and $p\,\rho$ refer to initial and final states of pressure and density, and γ is the ratio of specific heats of the gas. Thus $(1+\delta p/p_o)=(1+\delta\rho/\rho_o)^\gamma=(1+\gamma s)$ for small values of the condensation $s(=\delta\rho/\rho)$. Now $\kappa=\delta p/s$ (see equation 9). Therefore $\kappa=\gamma p_0$. Consequently *the velocity of sound is given by*

$$C=\sqrt{(k/\rho)}=\sqrt{(\gamma p_0/\rho_0)}. \tag{20}$$

Now Boyle's law indicates that p/ρ is a constant at constant temperature, consequently *the velocity is independent of the pressure* of the gas, for the density ρ changes in proportion to the pressure p.

Taking $p_o=10^6$ dynes/cm.^{2} and $\rho_o=0.00129$, and assuming $\gamma=1.41$ for air, we obtain a value for the velocity

$$c=3.31\times10^4 \text{ cms./sec. at } 0^\circ\text{ C.}$$

This is in good agreement with observation.

Change of Velocity with Temperature.—Since $\rho\theta=\rho_o/(1+\alpha\theta)$ where α is the temperature coefficient of volume expansion at constant pressure, and θ is the temperature in degrees centigrade, we have $c_\theta=\sqrt{[\gamma p_o(1+\alpha\theta)/\rho_o]}=c_o\sqrt{(1+\alpha\theta)}$. Now for any gas $\alpha=1/273$ per degree centigrade nearly, therefore

$$c_\theta/c_o=\sqrt{T/T_o} \tag{21}$$

where T and T_o are the absolute temperatures. That is, *the velocity* varies *directly as the square root of the absolute temperature. The velocity* given by (20) *is independent of frequency,* but is dependent on the nature of the gas. The velocity varies inversely

as the square root of the density, provided γ is the same—thus the velocity is four times as great in hydrogen as in oxygen.

Experimental Determinations of Velocity of Sound in Free Air.—The velocity of sound as measured in free air is affected by the wind, being greater with the wind than against it; in the first case the sum, and in the second the difference, of the velocities of the sound and the wind It is also affected by humidity The wind-velocity may be eliminated from the result by the method of reciprocal observation—the sound being produced first at one end and then at the other of a measured base line with a receiver also at each end. Alternatively the wind-velocity may be measured directly and a correction applied to the observed velocity of the sound. The latter method has been employed by Esclangon (*Comptes Rendus*, Jan 20, 1919). The sound-waves from guns of various calibres were received by sensitive electrical sound-detectors at 1400 m. and 14000 m. along the same line. The time intervals were measured to $\pm 0{\cdot}002$ second, the observations being made under various conditions of wind and humidity. The final result for the speed of sound in dry air at 15° C. was 339·9 metres per second which compares well with Regnault's value 339·7 metres/sec. (1863). Measurements of the velocity of sound at different levels (on mountain heights and plains) confirm the theory that there is no change of velocity with pressure Observations at low temperatures in the Arctic give a value $c_\theta = (333 + 0\ 6\theta)$ metres/sec at θ°C Other methods of measuring the velocity in free air are.—(1) *Echo methods*—the time t between the transmission of a sound and arrival of its echo from a reflector at a distance d being measured whence velocity $= 2d/t$, (2) *Coincidence Method*—The sound is transmitted at regular, accurately known, time intervals simultaneously from two points at a known variable distance apart When close together, the sounds are heard together but when one is moved further away the sounds are separated by an interval, at first increasing and then decreasing, till coincidence is again established The difference in distance between two such positions of coincidence, combined with a knowledge of the time intervals, gives a value of the velocity.

Probably the most accurate determinations were made during the war in connection with gun sound-ranging. Two sensitive resonant hot-wire microphones, at a known distance apart, received the gun-sounds which were automatically recorded by means of an Einthoven string galvanometer, the time intervals being measured to 0·001 second A large number of such observations, under different atmospheric conditions (wind, temperature and humidity), gave a value *337·16 m/sec at 10°C in dry air*, and *337·6 m/sec at 10°C. in air of average humidity*, the effect of humidity, producing a slight change of density, being therefore very slight.

Velocity in Tubes or Small Volumes of Gas Kundt's Dust Tube Method When a gas is only obtainable in small quantities the method of velocity measurement is entirely changed The best method available in these circumstances is one which is due to the work of Kundt. The gas is confined to a cylindrical tube containing a sprinkling of fine dry powder (lycopodium seed or cork dust) and is set into resonant vibration by any convenient means, *e g.*, by the longitudinal vibrations of a rod one end of which is inserted in the tube, or by the vibrations of the glass tube which contains the gas. The dust is heaped up in a repeated pattern indicating the nodes and loops in the vibrating gas column Rayleigh and Ramsey used this method to determine the ratio of specific heats γ of the rare gases argon and helium. The velocity c in a gas is given by $\sqrt{(\gamma p/\rho)}$ where p is the pressure and ρ the density. The value of γ found for the rare monotonic gases was 1·66. Kundt finally used a double-tube apparatus, in which stationary waves were produced simultaneously in two different gases by means of the same vibrating rod. The ratio of velocities in gas (1), rod, and gas (2), being equal to the ratio $\lambda_1 : \lambda_r : \lambda_2$, the values of λ_1 and λ_2 are obtained from twice the nodal separation (indicated by the dust heaps), and the value of λ_r is equal to twice the length l of the rod when sounding its fundamental longitudinal vibration. When the frequency N is determined (by monochord and tuning fork, or by a siren) the velocities c in the gas and the rod are known in absolute measure, for $c_{gas} = N\lambda_{gas}$ and $c_{rod} = N\lambda_{rod} = 2Nl$ Alternatively the vibrations may be communicated to the gas by means of a steel diaphragm (a telephone earpiece) one end closed and excited electromagnetically, the frequency being varied until resonance is set up in the gas contained in the tube This method has obvious advantages over the original "rod" excitation Using a short steel bar and exciting the vibrations by striking one end, Lang (*Proc Roy. Soc*, Canada, 1922) has observed the nodes and antinodes in a Kundt's tube up to a frequency of 50,000 cycles/sec The mean velocity of sound in the air contained in the tube (1 4 cms dia) was found to be 339·3 metres/sec. at 22·8° C., and in the steel bar 5120 m/sec approximately Kundt's tube method of measuring sound-velocities, and indirectly, the ratio of specific heats of gases, has been applied by Dixon, Partington and others to vapours and gases at various temperatures, and as a means of measuring temperature coefficients of sound-velocity

In Liquids.—As in the case of gases the velocity of sound in liquids is given by $\sqrt{(\kappa/\rho)}$, which κ is the adiabatic bulk modulus of elasticity Taking the isothermal compressibility C of *fresh water* to be 49×10^{-12} per dyne/cm², at 15° C the bulk modulus $\kappa(=1/c) = 2\ 04\times10^{10}$, and the velocity

$$\sqrt{(\kappa/\rho)} = 1{,}427 \text{ metres/sec.}$$

The value found by Colladon and Sturm (1826) in Lake Geneva was 1435 m/sec at a temperature of 8° C

Velocity of Sound in the Sea—The velocity of sound, particularly explosion-waves, has been measured in the sea by a number of observers with considerable accuracy Marti (*Comptes Rendus*, Aug. 1919) used three under-water microphones (hydrophones) in a straight line in Cherbourg roadstead, the total base line being 1800 metres The positions were accurately determined by theodolites The passage of the sound-wave due to an explosion under water in line with the hydrophones, was registered by an electric chronograph with smoked paper and tuning fork time-trace At a temperature of 14 5° C the velocity was found to be 1503 5 metres/sec in sea water of density 1·0245 gram/cm³ More recently a careful series of observations has been made by Wood, Browne and Cochrane near Dover with four hydrophones covering a base-line of twelve miles in the sea (*Roy Soc. Proc*, May 1923). Accurate temperature and salinity observations were made at points along the base line, and a new method (*multiple charge method*) devised to obviate errors arising through firing the charge at a point not quite in line with the base of hydrophones The time intervals of passage of the explosion wave between pairs of hydrophones was recorded on four strings of a six stringed Einthoven galvanometer (photographic), the ticks of an accurate chronometer on the fifth, and a wireless signal sent from a destroyer at the instant of firing the charge was recorded on the sixth string Thus the record showed to an accuracy of $\pm$·001 second the various *time differences and the total time of travel* of the explosion-wave to each receiver. The results obtained in summer and winter were 1510 4 m/sec at 16·95°C. and 1477 3 m/sec. at 7°C respectively, the salinity being 35‰ in both cases. (The theoretical values calculated by D J Mathews [*see* Tables for Velocity of Sound in Fresh and Sea Water—Stationery Office Publication H D 282 1927] are 1510·4 m/sec and 1476 1 m/sec respectively) The experimental results are expressed by the relation,

$$\textit{velocity} = 4756 + 13{\cdot}8\ t - 0{\cdot}12\ t^2\ \textit{ft per sec.} \qquad (22)$$

at 35‰ salinity (or $= 4626 + 13\ 8\ t - 0{\cdot}12\ t^2 + 3{\cdot}73\ s$ where s is the salinity in ‰ at the temperature t° C). The ratio of specific heats (isothermal and adiabatic) for sea water, deduced from these measurements, is 1·0094 as compared with 1·0090 obtained from thermodynamic data. The adiabatic compressibility at 16·95° C and 35‰ salinity is $43{\cdot}145\times10^{-12}$ per dyne as compared with Ekmann's isothermal value $42{\cdot}744\times10^{-12}$ per dyne.

Liquids in Tubes.—As in the case of gas-filled tubes stationary waves may be set up in tubes filled with liquid. On account of the small compressibility of a liquid compared with that of gas, however, a correction is required due to the yielding of the walls of the containing tube. This yielding produces an apparent lowering of the wave velocity—the lowering being smaller the thicker the tube. If c_0 be the theoretical velocity of sound in the liquid, and c the actual velocity in the liquid in a tube of small thickness h then

$$c_0 = c\sqrt{(1+2\kappa a/hE)} \qquad (23)$$

where a is the internal radius, K the bulk modulus for the liquid, and E the value of Young's modulus for the material of the tube (*see* Lamb's *Sound*, p. 174). In the other extreme, when the walls are very thick

$$c_0/c = \sqrt{[(\kappa+\mu)/\mu]} \qquad (24)$$

where μ is the rigidity of the material of the tube. Kundt and Lehmann succeeded in obtaining "dust" (fine iron filings) figures in liquids, as in gases, and thus measured the velocity of sound in tubes of different diameters and thickness. Application of Lamb's formula to their experimental values gives a mean value 1436 m/sec. at 19° C for the velocity of sound in open water. At frequencies within the audible range, the resonance of a liquid column can be observed by ear. The vibration is readily excited for example, by means of a steel diaphragm electro-magnetically maintained by current of variable frequency from a valve oscillator.

When the wave-length of the sound in the liquid is sufficiently small compared with the diameter of the tube the "correction" disappears. *Hubbard and Loomis* (*Nature*, Aug. 6, 1927 and *Phil. Mag.*, June 1928) using a quartz oscillator 100 mm. diameter emitting plane-waves at frequencies between 200,000 and 400,000, have determined the velocity of sound in various liquids in a tube, with an accuracy of 1 in 3,000. The results for fresh and salt water at different temperatures agree well with the values obtained by other observers for these liquids in bulk.

In Solids.—The velocity of sound in a solid rod of length l is very simply determined by observing the frequency N of its longitudinal vibration, the rod being clamped at the midpoint. The velocity is equal to $N\lambda$ or $2Nl$. The rod may be excited mechanically by striking or rubbing, or electro-magnetically. The velocity in steel or glass, for example, is about 5×10^5 cms./sec. as compared with $0{\cdot}33\times10^5$ cm./sec. in air and $1{\cdot}5\times10^5$ cm./sec. in water. The values of the velocity determined experimentally in this way agree very closely with the calculated velocities $\sqrt{(E/\rho)}$ where E is Young's modulus of elasticity. The converse of the method is therefore convenient as a means of determining E approximately. Lang (*loc. cit.*) has determined the velocity in short steel rods (5 cms.) vibrating at a frequency of 50,000 using Kundt's tube as a means of estimating the frequency. The values of velocity at supersonic frequencies are found to be the same as at audible frequencies. Apart from seismic observations there is little or no experimental data relating to the velocity of sound-waves in solids in bulk.

Velocity of Waves of Large-Amplitude.—*Explosion-Waves.*—Hitherto it has been assumed that the displacement-amplitude and condensation s are always small, and that the wave travels through the medium with velocity $c=\sqrt{(\kappa/\rho)}$ without change of type. If, however, the condensation becomes large, as in an explosion-wave, the velocity may be considerably modified for the curve connecting pressure p and density ρ is not a straight line. The bulk modulus, $\kappa=-v_0\partial p/\partial v=\rho_0\partial p/\partial\rho$, increases as the density ρ is increased by compression, and diminishes as the density is reduced. Consequently the compression wave travels faster and the rarefaction slower than a "small-amplitude" sound-wave. The result is a change of wave-form as a large-amplitude wave travels through the medium. Lamb (*Sound*, p. 177) shows that *the velocity of propagation is* $c(1+s)$ relative to the undisturbed medium (or $c[1+s]^{\frac{1}{2}(\gamma+1)}$ in the adiabatic case) indicating increase of velocity with increase of condensation s. The parts of the wave of greater density therefore gain continuously on those where it is less—*i.e.*, the crests tend to overtake the troughs, as indicated graphically in figs. 10a and b. The wave becomes steeper in front and more gradual behind. A continuation of such a process would eventually lead to a discontinuity when the wave-front becomes vertical—a condition which is physically impossible. As Rayleigh has remarked, such a tendency is held in check by the divergence of the wave and the influence of viscosity tending to diminish amplitudes and therefore reduce the velocity to its "normal" value. As an illustration, change of type in a progressive wave may be observed when sea waves approach a shelving beach. Here the crests gain on the troughs and the wave "fronts" become steeper and steeper until they curve over and break. A large amplitude explosion wave has initially a velocity considerably greater than ordinary sound-waves, gradually approaching this latter value as the distance from the origin increases. Regnault found that explosion-sounds increased in velocity with increase in the intensity of the explosion. Foley (*Nat. Acad. Soc. Proc.*, June, 1920) showed that the velocity of sound from an intense electric spark varied from 660 m./sec. at a distance of 3·2 mm. from the spark to 380 m./sec. at a distance of 18 metres. The shadow of the high pressure region near the wave-front of the sound-pulse was photographed at known short time intervals after the instant of production of the spark, the velocities at various distances being deduced therefrom.

Shell-Waves. Onde de choc.—When a bullet or a shell, travelling with a velocity greater than that of sound, passes an observer it makes a sound like the crack of an explosion—described by the French as "onde de choc." The tips of the propeller of an aeroplane often exceed the velocity of sound and emit sounds of this nature as they revolve. In the case of a low speed bullet, the air at the nose is compressed, the compression being transmitted in all directions with the velocity of sound (approximately 330m/sec. in air). If however, the speed of the bullet is greater than the velocity of sound the condensation of the air at the nose can be transmitted laterally *but not forwards.* Photographs taken of bullets while in flight show this clearly and reveal the existence of two wave-fronts, one at the head and the other at the base of the projectile. The former can be simply explained on Huyghens' principle of secondary wavelets. If the velocity of sound at the nose of the bullet were normal, the wave-front would be a cone of semi-angle $\sin^{-1}c/V$ (c normal velocity of sound and V velocity of projectile). But the velocity of sound increases with increased amplitude of condensation, consequently *the wave-front is a blunted cone,* as actually recorded in the photograph. From observations of the changing direction of the "onde de choc" it is possible to trace the bullet or shell to its source. (*See* Mallock, *Proc. Roy. Soc.*, p. 115, 1908.) This method was used in the war to locate enemy guns.

Velocity of High Frequency Sounds.—Using a quartz piezo-electric oscillator (*see* p. 12) as a source of high frequency vibrations, G. W. Pierce (*Proc. Amer. Acad.*, vol. 60, Oct. 1925) determined with considerable accuracy the velocity of sound in

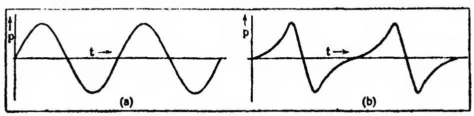

FIG. 10

air and carbon dioxide by the stationary-wave method. He found that the velocity of sound in air at 0°C has the values 331.94, 332.47 and 331.64 metres/sec. at frequencies 1,000, 50,000 and 1.5×10^6 p.p.s. respectively. The effect of humidity was negligible, at 80% humidity differing by less than 0·02% from the velocity in dry air. In CO_2 the velocity at 0° C was found to be 258·82 m/sec. at a frequency of 42,000 cycles/sec. increasing to 260·15 m/sec. at 200,000 cycles/sec. This gas becomes *opaque to sound-waves at still higher frequencies.* Boyle and Taylor (*Proc. Roy. Soc.*, Canada, 1925) observed a diminution of velocity

of high frequency sounds in water at 16° C from $1{\cdot}51 \times 10^5$ cms./sec. to $1{\cdot}42 \times 10^5$ cms./sec. at frequencies 43,000 and 398,000 cycles/sec. respectively. The measurements were made in a small tank. The velocity in a viscous oil was found to be the same at 570,000 cycles/sec. as at low frequencies. Lang (*Roy. Soc.*, Canada, 1922) found no change in the velocity of sound in steel bars at any frequency up to 50,000 cycles/sec. Reference has already been made (p. 22) to the piezo-electric measurements of Hubbard and Loomis on the velocity of sounds of frequency 3×10^5 in various liquids contained in tubes.

Change of Medium. Reflection and Transmission.—As in the case of light, when a wave of sound meets the surface of separation of two different media it is partially reflected, and a wave travels back (in the negative direction) through the "incident" medium, with the same velocity as it approached the bounding surface. The laws of reflection are the same as applied to light waves—angles of incidence and reflection being equal and in the same plane. With sound-waves however, we have often to deal with wave-lengths which are comparable with the dimensions of reflecting objects; the phenomena must then eventually be regarded primarily as diffraction. In the cases which we are now considering the wave-length may be regarded as small, or the reflector large, the ordinary optical laws being applicable.

Reflection of Plane-Waves at the Boundary of Two Extended Media.—It is shown in text-books of sound (Rayleigh, vol. ii, p. 81) that the relative amplitudes r and a of the reflected and incident waves are given by

$$\frac{r}{a} = \frac{\rho_2/\rho_1 - \cot^1\theta_2/\cot\cdot\theta_1}{\rho_2/\rho_1 + \cot\theta_2/\cot\cdot\theta_1} \qquad (25)$$

where ρ_1 and ρ_2 are the respective densities of the first (incident) and second (transmitting) media and θ_1 and θ_2 are the angles of incidence and refraction. The *law of sines* of optical refraction holds in this case also, and we have $\sin\theta_1/\sin\theta_2 = c_1/c_2$, where c_1 and c_2 are the velocities in the first and second media. Consequently (25) may be written

$$\frac{r}{a} = \frac{\dfrac{\rho_2}{\rho_1} - \dfrac{c_1\cos\theta_2}{c_2\cos\theta_1}}{\dfrac{\rho_2}{\rho_1} + \dfrac{c_1\cos\theta_2}{c_2\cos\theta_1}} \qquad (26)$$

which becomes

$$\frac{r}{a} = \frac{\rho_2 c_2 - \rho_1 c_1}{\rho_2 c_2 + \rho_1 c_1} \qquad (27)$$

at "*normal*" *incidence* (when $\theta_1 = \theta_2 = 0$). If the velocity in medium (2) be greater than in medium (1), the incident waves being in the *slower velocity* medium, there will be a *critical angle of incidence* ($\sin\theta_1 = c_1/c_2$) which, if exceeded, will result in *total reflection.*

As an example, let air and water be the media (1) and (2), sound waves being incident normally on the surface of the water. Equation (27) which *expresses the reflection-amplitude in terms of the radiation impedances* $\rho c (= \sqrt{\kappa\rho})$ *per unit area of the two media* (see above) gives $r = 0{\cdot}99943a$, since the values of ρc for water and air are 14×10^4 and 40 respectively. In such a case, *where the radiation impedances are widely different, there is almost complete reflection,* even at normal incidence. The transmission is a maximum and reflection zero when $\rho_1 c_1 = \rho_2 c_2$, that is, when the radiation impedances of the two media are equal.

Reflection of Plane Waves from a Plate of Finite Thickness.—This case is analogous to the optical example of reflection from a thick plate of glass—the reflected wave being the resultant of multiple reflections at the two bounding surfaces. The ratio of reflected and incident amplitudes for normal incidence now becomes

$$\frac{r}{a} = \left(\frac{\rho_1 c_1}{\rho_2 c_2} - \frac{\rho_2 c_2}{\rho_1 c_1}\right) \Big/ \left\{4\cot^2\frac{2\pi l}{\lambda_2} + \left(\frac{\rho_1 c_1}{\rho_2 c_2} + \frac{\rho_2 c_2}{\rho_1 c_1}\right)^2\right\}^{\frac{1}{2}} \qquad (28)$$

where l is the thickness of the plate and λ_2 the wave-length of the sound in it, $\rho_1 c_1$ and $\rho_2 c_2$ being the respective radiation resistances of the medium (1) and the plate (2). Boyle and Rawlinson (*Proc. Roy. Soc.*, Canada, 1928) have deduced a more general expression for any angle of incidence, and have determined the "critical angle" at which total reflection occurs. It will be seen that the reflected-amplitude r fluctuates between zero and a maximum as the thickness of the plate varies. In the case where $c_2 > c_1$ the reflected amplitude is *zero* when $l = 0$ or a multiple of $\lambda/2$, and reaches its maximum value when l is a multiple of $\lambda/4$. A *quarter wave-plate* consequently reflects a maximum and transmits a minimum of the incident sound-energy.

These relationships for the reflection of plane-waves from flat plates have been verified by Boyle and Taylor and Boyle and Lehmann in the case of high frequency sound-waves passing through water in which the plate was submerged. Equations (26) (27) and (28) indicate that solid media in air are practically perfect reflectors, whereas in water they are relatively good transmitters of sound. An air film in water or in a solid mass constitutes a perfect reflector, with a reversal of phase at reflection. The practical application of such deductions is dealt with by H. Brillié (*Le Génie Civil*, Aug. and Sept. 1919) in relation to the problem of sound-reception under water.

Stationary Waves.—*Reflection and Absorption Coefficients of Materials.* It has been shown in the case of strings that the resultant displacement y at a point in the stationary-wave formed by combining the direct and reflected-waves is given by

$$y = a\cos n(t - x/c) - a\cos n(t + x/c) = 2a\sin nt\sin(nx/c).$$

The same relation applies to longitudinal-waves of condensation reflected normally from a plane perfectly reflecting obstacle. If, however, the obstacle is not a perfect reflector some of the incident sound energy is absorbed or transmitted. Consequently the reflected-amplitude r is less than a. The expression for y now becomes

$$y = (a + r)\sin nt\sin(nx/c) + (a - r)\cos nt\cos(nx/c) \qquad (29)$$

in the case of perfect reflection ($r = a$) we obtain the ordinary expression for stationary-waves The general expression (29) is applicable to all cases, and is represented by fig. 11. The incident energy is proportional to a^2 and the reflected energy to r^2. The reflection coefficient of the obstacle is defined as the ratio r^2/a^2. Equation (29) represents two superimposed stationary-waves of maximum-amplitudes $(a+r)$ and $(a-r)$ respectively, and displaced $\pi/2$ in phase. Consequently the maximum and

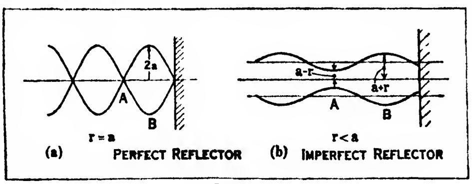

FIG 11

minimum-amplitudes of the *resultant* stationary-wave are proportional to $(a+r)$ and $(a-r)$ respectively. If we write

$$\alpha = (a + r) \text{ and } \beta = (a - r),$$

then the reflection coefficient

$$\frac{r^2}{a^2} = \left(\frac{\alpha - \beta}{\alpha + \beta}\right)^2 = \left(\frac{1 - \beta/\alpha}{1 + \beta/\alpha}\right)^2 \qquad (30)$$

This expression for the reflection coefficient, in terms of the ratio min./max. amplitude in the stationary-wave, serves as a basis for experimental methods of measuring the reflecting properties of materials and, of course, their absorption or transmission properties. The absorption coefficient (which is generally assumed to include transmission) is given by

$$(a^2 - r^2)/a^2 = 4/(2 + \alpha/\beta + \beta/\alpha).$$

This method of determining sound absorption coefficients of

materials was developed by Tuma (1902), Weisbach (1910) and Hawley Taylor (1913). More recently Paris (*Roy. Soc.*, 1927 and *Phys. Soc. Proc.*, 1927) has refined the experimental procedure by using the hot-wire microphone to obtain accurate values of the ratio β/α, and consequently of the reflection and absorption coefficients. The plane stationary-waves were produced in a tube closed at one end by the reflector under test. The absorption coefficient was found to increase with increasing thickness of the absorber (*e.g.*, felt) and with increase in the frequency of the sound. Such measurements have an important application in the acoustics of buildings *q.v.* Stationary waves may readily be demonstrated when a high pitched sound, from a bird call or Galton's whistle, is reflected normally from a plane solid obstacle. A sensitive flame flares at all points in the path of the wave except at the nodes.

Echoes.—The direct reflection of a sound of short duration from a surface of large area such as a wall or a cliff results in what is familiarly known as "echo". The time-interval t between the initiation of a sound-impulse and the reception of the echo at the same point of observation is given by $t=2d/c$ where d is the distance of the reflector and c is the velocity of sound in the intervening medium. Measurements of t will therefore lead to a value of the velocity c or the distance d according to which of these two quantities is previously known. The principle has important practical applications (*e.g.*, see *Echo Depth Sounding*, p. 35) in the measurement of distance.

Harmonic Echoes.—If the primary sound has a complex wave-form, containing high harmonics of a fundamental tone, the component tones will be scattered or diffusely reflected in unequal proportions. The amplitude of the secondary-waves varies inversely as the square of the wave-length (and intensity as $1/\lambda^4$), consequently the higher harmonics of the complex wave are scattered back in far greater proportion than the fundamental. To an observer near the source, therefore, the returning echo appears to be raised in pitch one or more octaves according to the nature of the primary sound.

Reflectors as Sound Screens.—To produce shadows comparable with optical shadows, it is essential that the reflector should be large compared with the wave-length of the sound employed. The high pitched tick of a watch may be effectively screened by a relatively small reflector but the sound of a man's voice or of a motor horn requires a much larger screen. The wave-lengths in the two cases vary from a few inches to several feet, and the linear dimensions of the reflector must consequently vary in the same proportion to produce the same degree of screening. Behind the reflector the sound is generally found to have changed in quality, the high frequency components being more perfectly screened than the lower frequencies—on this account the sound appears to be "purified."

Musical Echoes from Palings. Echelon Reflectors. (Gratings).—If a sharp sound is made near one end of a row of palings, or similar "stepped" structure, the echo takes the form of a musical note. The successive palings each reflect the impulse (or, selectively, its higher harmonics) and the observer receives a succession of reflections which, if sufficiently rapid, blend into a musical note. The time intervals δt are equal to $2\delta x/c$, where δx is the path difference to the successive reflectors, consequently the frequency N of the note will approximate to $C/2\delta x$ or some higher harmonic. If, for example, near a row of palings $\delta x=4$ inches, and $c=1100$ ft./sec., N will be a multiple of 1650 cycles/sec. *i.e.*, a high pitched note. An echelon structure of this kind serves as the equivalent of a "grating" by which complex high frequency sounds might be analysed (*see* p. 26).

Reflection at Curved Surfaces. *Spherical Mirrors.*—It is shown in books on Optics that a parallel beam (plane-waves) of light when incident on a spherical mirror will be brought to a focus at a distance from the pole of the mirror equal to half the radius of curvature, and conversely a parallel beam of light emerges from such a mirror when a small source is placed at the focus. Similar results are observed with sound-waves of high frequency and reflectors of moderate dimensions.

Whispering Gallery Effects.—The well known whispering gallery of St. Paul's Cathedral, London, owes its peculiar acoustical properties to the reflection of sound by the walls. The gallery takes the form of a circle around the base of the dome. The exact mode of action is still a moot point. Rayleigh (*Sound*, vol. ii., p. 126) pointed out that the sound tends to creep round the inside of a curved wall, being continuously reflected by the wall, without ever getting far from it. "A whisper seems to creep round the gallery horizontally, not necessarily along the shorter arc, but rather along that arc towards which the whisperer faces. This is a consequence of the very unequal audibility of a whisper in front of, and behind, the speaker. The abnormal loudness with which a whisper is heard is not confined to the position diametrically opposite to that occupied by the whisperer and therefore, it would appear, does not depend materially on the symmetry of the dome." It should be noted that whispers contain a higher proportion of high pitched sounds than ordinary speech, and whispering is heard more distinctly than ordinary conversation especially if the speaker looks along the gallery towards the listener. C. V. Raman (*Ind. Assoc. Sci. Proc.*, 1922) describes an investigation of 5 whispering galleries in India which confirm a view held by Sabine of the importance of the inward slope of the wall of the gallery for giving the best effects, and the concentration by a spherical dome of a maximum sound at the opposite end of a diameter. Multiple sounds which are observed are shown not to be echoes, but sound-waves travelling circumferentially round the gallery several times before they are appreciably diminished in intensity.

Rayleigh suggests that the propagation of earthquake disturbances is probably affected by the curvature of the surface of the earth acting like a whispering gallery. It is not improbable also that sounds travelling long distances in the sea are dependent on a similar action, and on repeated reflection at the surface and bottom. Taking the depth of a sea as uniformly 24 fathoms (144 ft.) the maximum possible distance of *direct propagation* of a sound-wave in it will be 29·3 miles approximately —whereas ranges 2 or 3 times this value have actually been observed in the North sea. The possibility of a curved path due to temperature gradients must also be considered in seeking an explanation of these long ranges in the sea.

Refraction of Sound-Waves.—The optical analogy which applies to reflection of sound may, as we have already seen, apply to refraction also. When plane-waves of sound cross the bounding surface between two different media having different wave-velocities c_1 and c_2 the direction of propagation is changed in accordance with the sine law, viz., $\sin\theta_1/\sin\theta_2=c_1/c_2$ where θ_1 and θ_2 are the angles of incidence and refraction respectively. Hence the sound "rays" in passing from one medium to another are bent towards or away from the normal according as the velocity of the wave in the first medium is greater or less than in the second medium. Thus, for example, sound is refracted towards the normal when passing from air into CO_2. The "critical angle", when the sound is totally reflected, and there is no refracted beam, is given by $\sin\theta_1=c_1/c_2$. The critical angle from air to water, $c_1=1,100$ ft./sec. and $c_2=4760$ ft./sec., is therefore $13\frac{1}{2}°$ approximately; above this angle no sound whatever can enter the water (we have already shown, p. 23, that even at normal incidence the reflected amplitude is 0·99943 of the incident amplitude). From air to solid materials (steel, glass, wood, etc.) $c_1/c_2=0{\cdot}065$ approx. whence the critical angle is $3\frac{1}{2}°$. Sondhauss (1852) demonstrated the refraction of sound through prisms containing various gases, and determined the refractive index μ relative to air, $\mu=\sin\theta_1/\sin\theta_2=c_1/c_2$. He was also successful in demonstrating the focusing action of a convex lens of carbon dioxide enclosed in a thin envelope of collodion.

Refraction by Wind and Temperature Gradients.—It is well known that sound travels better with the wind than against it. This effect is due to the increase of velocity of the wind from the earth's surface upwards. The effective velocity of sound is

equal to its normal velocity $\sqrt{(\gamma p/\rho)}$ plus or minus the velocity of the medium. In still air the wave-front of a sound-beam will travel over the earth's surface parallel to its initial direction, say at right angles to the ground. If, however, a wind is blowing in the same direction, the upper part of the wave where the wind velocity is greater, travels faster than that part near the ground, with the result that the wave-front tends to bend downwards towards the ground. An observer therefore hears by a direct ray which starts with a slightly upward inclination. Similarly a horizontal ray travelling against the wind is bent upwards and, at a moderate distance, passes over the head of an observer A similar effect may be noticed when there is a gradual change in the temperature of the air from the ground upwards The warmer the air, the greater the velocity of sound. If the temperature increases upwards, the wave-front will be bent downwards towards the ground; conversely, when the temperature diminishes upwards the sound-beam will be deflected upwards into the higher atmosphere and lost. The curvature of the ray is given by $1/R=-1/c\cdot\partial c/\partial y$ where $\partial c/\partial y$ is the velocity gradient with respect to height—this gradient may be positive or negative.

Audibility of Fog Signals Tyndall (*Phil. Trans.*, 1874) made extensive researches on the audibility of fog signals across the Channel from South Foreland, and came to the conclusion that "temperature refraction" and a "flocculent" condition of the atmosphere, arising from unequal heating or moisture, were responsible for large fluctuations in the observed ranges of audibility. Contrary to general opinion at the time Tyndall found that the presence of fog favoured the transmission of sound signals--the atmosphere being then in a more homogeneous condition, particularly in regard to temperature gradients The problem of long-distance transmission of signals has recently been studied by King, Tucker, Paris and others. Using a doubly-resonated hot-wire microphone, Tucker and Paris have made intensity measurements at varying distances and orientations with respect to diaphones and sirens mounted in light-houses at sea In a particular experiment it was found that the ratio of sound intensities at two miles from the source, *with* the wind and *against* it was 25 to 1. The effects of temperature refraction were also partly responsible for this high value of the ratio at such a short range. Certain fluctuations of intensity were ascribed to moving eddies in the atmosphere. Player, however, as a result of recent observations of a similar nature, reached the conclusion that humidity is the only factor in which the variations are at all comparable with the large and sudden variations in the range of audible transmission.

Zones of Silence. The sound of a large explosion is sometimes observed at very great distances, whilst at intermediate distances nothing at all is heard Thus the explosion of a large ammunition dump in Holland (Jan. 1923) was recorded at a distance of 850 km. whereas at 100 to 180 km. no sound could be detected. These intermediate zones of silence are not uncommon in such cases. They doubtless arise as a result of peculiar meteorological conditions at the time of the explosion. As we have seen, the action of temperature and wind gradients may cause upward or downward refraction of the sound. Esclangon (*Comptes Rendus*, 1924) has shown that these two factors are sufficient to account for one or a succession of zones of silence, with reinforcement of sound in particular directions. Zones of silence are in certain cases due to the interference between sound-waves reaching the observer by different paths. (See *Interference* above.)

Effect of Temperature Gradients on Sound Propagation Under Water.—The sea is a much more homogeneous medium for sound-transmission than the atmosphere. Sounds of moderate power may be heard at long ranges, 40 or 50 miles, without the corresponding fluctuations of intensity which are so troublesome in air. The effects of tidal currents (analogous to "wind"), say 10 ft./sec., are in most cases negligible, the velocity of sound in water being about 5,000 ft./sec. Seasonal variations in range of signals have been observed (*see* H. Lichte, *Phys. Zeits.*, Sept. 1919) these being ascribed to refraction produced by temperature gradients in horizontal layers of the sea. Such a temperature gradient may cause a sound "ray" to curve *upwards* to the surface where it is reflected down again, only to rise once more In this way it travels forward along a cycloidal or "festoon" type of track. A temperature gradient of opposite sign causes a bending *downwards* with analogous effects at the sea bed. Surface and bottom reflections play an important part in the long-range transmission of sound in the sea. With a particular sound-transmitter Lichte and Barkhausen (*Ann. d. Physik*, 62, July 1920) noted a change from 10 km. in summer to 20 km. in winter in the Baltic sea

Interference.—The passage of sound-waves through a medium is in no way affected by the passage of other sound-waves through the same part of the medium. This important principle involving the independence of separate trains of waves is known as the *Principle of Superposition* and was first propounded by Huyghens in dealing with light-waves. The resultant displacement of a particle of the medium is obtained by adding the separate displacements vectorically (*see* p. 20) Thus two periodic motions of the same frequency, of amplitudes a_1, and a_2, and phase difference ϵ combine to form a periodic motion having an amplitude whose square is $(a_1^2+a_2^2+2a_1a_2 \cos\epsilon)$. The principle of superposition applied to the *squares* of amplitudes (*i.e.*, energies) would account for the first two terms only and the results would be erroneous. It is found under certain conditions that two trains of sound-waves may, at certain points in the medium, neutralize each other's effects and produce silence where previously there was a definite sound due to either of the trains of waves Thus in the above case, if $\epsilon=180°$, *i e*; the two independent sets of vibrations of the particle are in opposite phase $\cos\epsilon=-1$, and the resultant amplitude is (a_1-a_2), which becomes zero when $a_1=a_2$; if $\epsilon=360°$ or $0°$, $\cos\epsilon=+1$ and the resultant-amplitude is (a_1+a_2) or $2a$, when $a_1=a_2$. When the observed sound-distribution due to two or more wave-trains of sound is not found to be equal to the sum of the separate wave-trains, the latter are said to have interfered with each other and the phenomenon is described as interference. Interference is a direct result of the principle of superposition. The phenomena of interference may be observed in any smooth water surface which is disturbed simultaneously at two different points. J. H. Vincent has obtained very beautiful photographs of such effects on the surface of mercury (see *Phil. Mag.*, 1897, 8 and 9). The crests and troughs of the two sets of ripples in certain places reinforce each other, whilst in others they neutralize; the result is a definite "interference pattern" superposed on the ordinary wave systems When sounds of the same frequency and amplitude reach the ear by different paths, or originate with different phases, interference effects may readily be observed. Thus the waves sent out from the prongs of an ordinary tuning fork interfere, producing approximate silence in certain directions and increased intensity in others—the rise and fall of intensity, four times per revolution, as a vibrating fork is rotated near the ear is easily demonstrated. Any "double-source" of sound, such as a vibrating diaphragm exposed on both sides, shows these effects. If sound is led from its source to a receiver by two tubes of equal diameter and length the two sets of waves will arrive together, *i e.*, in phase. If the length of one tube is gradually varied relatively to the other the path difference will be successively $\lambda/2$, λ, $3\lambda/2$, 2λ, and so on, the resultant effect at the receiver alternating between zero, and maximum. These phenomena can be demonstrated by means of a tuning fork and two tubes of adjustable length, with a common exit placed to the ear. *Stationary-waves* to which we have already referred (p. 23) form a good example of the interference between a primary and a reflected train of waves Interference between the waves from two sources of sound of *nearly* equal frequency appears as an increase and decrease of intensity *with time*—known as the phenomenon of *beats* (*see* p. 6) and exemplified by two tuning forks of nearly equal pitch In certain cases the *zones of silence* observed by Tyndall when listening on a ship to the sound of a fog siren on a neighbouring cliff, were ascribed to the interference between the *direct* sound

beam with that *reflected* from the surface of the sea—if these paths differ by any odd multiple of half a wave-length the two trains of waves neutralize each other and the siren is not heard. Wood and Young (*Proc. Roy. Soc.*, 100, 1921) observed interference zones *under* water due to a similar cause. Such effects are of considerable importance in the case of *long distance sound transmission in the sea.* The sound-wave is reflected *with reversal of phase* when it reaches the water-air surface. At a considerable distance from the source, the path difference between the direct and surface-reflected wave may become very small compared with the wave-length, resulting in almost complete neutralization. Fortunately, however, the surface of the sea is never smooth and the sea-bed reflects sound very efficiently. The bottom-reflected-wave may therefore, in certain cases, be solely responsible for the sound heard at long ranges.

Diffraction. *Sound-Shadows.*—The bending of sound-waves round the edges of obstacles is one of the most familiar of everyday observations. If it were not for this effect, short distance intercommunication by means of sound would be much more difficult. Fast motor traffic on our roads is vitally dependent upon such a possibility at turnings and crossings. This bending of sound "round the corner" may be regarded as evidence of its nature as a form of wave motion; the effect being similar to that of "diffraction" in the case of light-waves. The sound-shadow and the geometrical shadow of an obstacle are therefore not coincident. The study of diffraction effects is greatly assisted by the use of a principle which is due to Huyghens:—*The wave-front of a disturbance may at any instant be obtained as the envelope of the secondary-waves proceeding from all points of the wave-front at some preceding instant.* A disturbance diverging from a point source with velocity c may at any time t_1 be represented by a thin spherical shell. This shell may therefore be regarded as the disturbed region, and the disturbance at a subsequent time t_2 determined by drawing spheres of radii $c(t_2-t_1)$ round each point of the shell. The outer spherical envelope of these spheres will be the new wave-front at the instant t_2. By this construction it will be found that the direction of advance of the wave is normal to the wave-front. Huyghens' principle of secondary-waves is directly applicable to diffraction problems provided that due allowance is made for the contribution of each surface element of the wave-front to the *amplitude* at the point P under consideration. This estimation of amplitude involves the use of a device due to Fresnel—in which the initial wave-surface is divided into "half-wave zones" (*see* text-books on Optics). These zones are such that their resultant effects at some distant point P are alternately in opposite directions (being $\lambda/2$ different in path length measured from P). Two successive zones therefore neutralize each other's effects at P.

Plane-Waves of Sound Passing a Straight Edge.—Employing the Huyghens-Fresnel principle the distribution of sound beyond the edge of a totally reflecting wall may be determined. *Outside* the geometrical shadow there is a fluctuation of intensity which settles down, after a few oscillations, to the normal value in the absence of the wall. *Inside* the geometrical shadow the intensity steadily falls off from one quarter its normal value at the edge to zero at some distance inside the geometrical shadow. The relatively feeble diffracted sound behind the wall is easily observed by the ear if the incident sound-wave is of audible frequency and of moderate intensity. With high pitched sounds (*e.g.*, from a Galton's whistle or a high frequency diaphragm excited electro-magnetically) and a sensitive receiver the variations of intensity at a diffracting edge can be observed experimentally. A sensitive flame may be used as the indicator of sound intensity or alternatively, if the sound is in the audible range, a stethoscope tube with a small funnel opening may be used to listen directly. The gradual fading away of sound within the geometrical shadow is a common observation at all frequencies.

Circular Obstacle. Scattering of Sound-Waves.—Constructing Fresnel zones outside the edge of a circular obstacle, it will be found that the total effect at a point on the axis is equal to half the effect of the first zone, *i.e.*, the same as if no obstacle at all were interposed This is true whatever the size of the disc relative to the wave-length of the sound. Immediately surrounding the central spot there is a ring of almost complete silence and beyond that a further increase of intensity, and so on. These effects can be demonstrated in the manner suggested above for a straight edge. This case is analogous to that of the bright spot at the central point of the optical shadow of a circular disc—one of the "classical proofs" of the wave theory of light. It finds an important application in the directional reception of sound (*see* p. 28).

Scattering by Small Obstacles.—Rayleigh has shown that the intensity of the sound scattered in all directions by an obstacle is directly proportional to the volume of the obstacle and inversely proportional to the fourth power of the wave-length of the sound. This law also applies to the scattering of light and is used to explain the blue colour of the sky. We have already referred to an illustration in sound, viz., harmonic echoes, in which the higher constituents of a complex sound are scattered more readily than the fundamental, with the result that the scattered or diffusely reflected sound appears raised in pitch by one or more octaves.

Circular Aperture.—The transmission of sound through a circular opening in an extended wall has already been considered in the analogous case of sound radiation from a piston (such as a Langevin quartz oscillator), the sound distribution beyond the opening consisting of a primary beam and a number of secondaries separated by silent regions. An experiment showing the antagonism between the parts of a wave corresponding to the first and second Fresnel zones is described by Rayleigh (*Sound*, Vol. II., p. 141). Sound-waves from a high pitched source fall on a screen with a circular opening of variable diameter. A sensitive flame is situated on the axis on the opposite side of the screen. The flame is unaffected by the sound which gets through a large opening, comprising two opposed Fresnel zones but flares violently when the area is *reduced* to one zone.

Zone Plates.—Let circles be drawn, on a plane reflector, with radii, $r_1\, r_2\, r_3$, etc., given by $r_n^2 = n\lambda d$ where $n = 1, 2, 3$, etc., and d is the distance of the centre O from a point P on the axis normal to the reflector. The circles divide the surface of the reflector into Fresnel half-wave zones with respect to the point P. It will be seen that these annular zones are of equal area. If alternate zones are cut away, a plane sound-wave falling on the plate and passing through the annular openings *will arrive in phase at* P, resulting in a considerable increase of intensity at that point. A *zone plate* of this kind therefore acts like a convex lens of focal length $OP = f = r_n^2/n\lambda$, r_n being the radius of the nth zone and λ the wave-length of the sound. The focusing properties of such zone plates were demonstrated by Rayleigh by means of high pitched sounds and sensitive flames.

Diffraction Gratings. Reflection from Stepped or Corrugated Surfaces.—The diffraction grating, so familiar in optics, has its counterpart in sound. When sound-waves are reflected from a regular periodic structure, such as a row of palings or a corrugated surface, the reflected-waves may assist or neutralize each other in certain directions depending on the wave-length λ of the sound and the spacing d of the reflectors. The diffracted-waves have maxima in directions θ given by $\sin\theta = \pm n\lambda/d$ where $n = 1, 2, 3$, etc. When d is smaller than λ there are no diffracted waves and the incident beam is reflected in the ordinary way. Thus a row of palings or a rough wall reflects sounds of moderate pitch like a perfectly smooth surface, little or no sound being returned towards the source, except in the case of normal incidence. When the sound is high pitched, however, λ being less than d, it is thrown back in all directions reinforcing along certain lines and neutralizing in others. A regular row of palings may serve as a "reflection" or a "transmission" grating. W. Altberg (*Ann. d. Physik*, 23, 1907) demonstrated a diffraction grating of this nature by means of glass rods 1 cm. apart, using a concave reflector to produce plane-waves of sound incident on the grating. The sound was produced by means of a high

frequency electric spark emitting waves only a few millimetres in length. A second concave mirror received the diffracted sound and brought it to a focus at a sensitive detector. The sound spectrum was obtained by rotation of the grating with respect to the source and receiver. Wave-lengths of the order 0·2 mm., corresponding to a frequency 1·5 million per second, were measured in this way.

Experimental Study of Wave Transmission.—Many of the "optical" characteristics of sound which we have mentioned may be studied on a laboratory scale by the following methods: (a) *Spark Photography.* The progress of a sound pulse may be observed either by the "Schlieren Method" (due to Töpler 1867) or the "Shadow Method" (due to Dvořák 1880). In the latter case, the sound pulse is produced by an electric spark (the *sound* spark), followed by a second spark (the *light* spark, between magnesium electrodes) at a known short interval of time. The highly compressed region forming the envelope of the sound pulse casts a shadow, when illuminated by the light spark, on a screen or a photographic plate. A succession of photographs at varying time-intervals after production of the sound-spark indicates the progress of the sound-pulse. The various phenomena of reflection, refraction and diffraction have been demonstrated in this way (*see* for example, Foley and Souder, *Phys. Rev.*, 35. 373. 1912). Photographs of this nature are shown in Plate I, figs 1a to f. (b) *Ripple Photography.* Results of a similar character may be obtained more easily by means of the ripple tank. This method is based on the fact that impulsive ripples on the surface of a liquid, *e g*, water or mercury in a small tank, bear a striking resemblance to impulsive sound-waves. The ripples are reflected, refracted and diffracted from objects placed in the liquid for observation purposes. The method was first used by Vincent (*Phil. Mag.*, 43 17. 1897) to demonstrate interference phenomena, but more recently it has received a wider application in the study of complex reflections occurring in models of buildings (*see* Article on ACOUSTICS OF BUILDINGS; and Davis, *Proc. Phys. Soc.*, 38 234. 1926). (c) *Bullet photography.* The "bow" wave from a high speed bullet (*see* Plate I. fig 2) has been utilised to demonstrate the reflection and diffraction of a sound-pulse. Thus in C. V Boys photographs of a bullet in flight (*Nature*, 47 415. 440 1893) the pulse is seen to be reflected according to optical laws. Cranz (*Handbuch der Physik*, Vol. VIII, Geiger and Scheele) has photographed the track of a bullet passing between two parallel plates, and the multiple reflections of the bow-waves are beautifully shown. The method is not so convenient as the spark and ripple methods, but it possesses certain novel features.

Doppler's Principle.—*Moving Sources and Receivers.*—The pitch of a sound is liable to be modified when the source and receiver are in relative motion. Thus an observer approaching the source with velocity v will encounter more sound-waves per second than if he had remained at rest, the number of sound waves per second (the pitch of the note) being increased in the ratio $(c+v)/c$ where c is the normal velocity of sound in the medium. Similarly when the observer is at rest and the source moving, the change of pitch will be in the ratio $(c\pm v)/c$ according as the source is approaching or receding. The whistle of a locomotive is raised in pitch as it approaches, and falls in pitch as it recedes from an observer. The principle of change of pitch by relative motion is due to Doppler, who first enunciated it in connection with the change of colour of certain stars moving in the line of sight of an observer. If the medium is also in motion (*e.g.*, wind) with velocity w in the direction of the sound-wave, the observed pitch N^1 relative to the actual pitch N will be $N^1/N=(c\pm w\pm v)/(c\pm w)$. When $v=0$, $N^1=N$ irrespective of the velocity of the medium. The latter velocity w only affects the ratio N^1/N slightly when the source and observer are in relative motion also The Doppler effect can be produced in the laboratory by the simple expedient of rotating a maintained source of sound at the end of a bar or cord. Preferably the source should be maintained in vibration by virtue of the rotation. The observer in the plane of rotation hears a note which rises and falls in pitch once per revolution. The observed pitch of the sound from an aeroplane may vary by 20% according to the speed and direction of flight.

Attenuation of Sound-Waves. Viscosity and Heat Conduction.—We have hitherto considered plane or spherical waves travelling through various media without loss of energy. Apart from other considerations it will be evident that energy loss must take place wherever there is relative motion between the various particles comprising the medium, such loss being due to ordinary viscous forces which tend to degrade the sound energy into heat. In addition to this viscous loss there must be energy loss due to thermal conduction and radiation consequent on the compression and rarefaction of the medium. If the compressions and rarefactions succeed each other with sufficient rapidity the process will be strictly adiabatic, that is, there will be no transfer of heat between compressed and rarefied regions or to the parts of the medium unaffected by the sound-wave. Sound-waves of small amplitude in air are propagated under almost perfectly adiabatic conditions. Otherwise, as Stokes proved in 1851, the sound would be rapidly stifled, which is contrary to experience In the case of sounds of very large-amplitude however (an explosion impulse, or the sound-wave emerging from a very powerful source), it is conceivable that the large temperature fluctuations in each cycle of pressure may be such as to involve appreciable temperature losses due to conduction and radiation even in a very short time interval. This would result in a more rapid decrease of sound-energy with distance than the inverse square law requires, the effect becoming increasingly serious the lower the frequency and the greater the amplitude of the sound waves With regard to energy loss due to viscosity, Maxwell pointed out that the factor involved is the "kinematic viscosity coefficient" ν, which is equal to the ordinary "static" coefficient μ divided by the density ρ Thus for air $\nu=0\cdot132$ and for water $\nu=0\cdot013$ at 10° C. The amplitude ξ of the progressive wave therefore diminishes exponentially on account of energy loss on the way In the case of plane-waves we have

$$\xi=ae^{-x/l}\cos n(t-x/c)$$

where l is the distance travelled by the wave before the amplitude falls to $1/e$ of its initial value. In this expression $l=(3c/8\pi^2\nu)\lambda^2$, indicating a rapid increase of attenuation with diminishing wave-length λ (*i e.*, with increase of frequency). To include the losses due to heat conduction also Maxwell multiplied ν in the above expression by 2 5, the effect being therefore equivalent to a marked increase (to ν^1) of kinematic viscosity. On the above grounds there is clearly a physical upper limit to the frequency of vibration which can be transmitted an appreciable distance[1]. Rayleigh (Vol 11, p. 28) concludes that the effects of energy losses of the above nature are to be sought for in the damping of the vibration rather than in the altered velocity of propagation. It should be mentioned that changes of velocity with frequency have actually been observed by Pierce in air and CO_2 and by Boyle and Taylor in water, although no such change could be detected by Lang in the case of steel bars.

With regard to attenuation there is ample evidence confirming the above theory which indicates a rapid decrease of range with increasing frequency. For example in air, for sound-waves of frequency 1000, $\lambda=33$ cms., we find $l=40$ kilometres since $\nu^1=2\cdot5\nu=0\cdot33$ for air. The value of l at a frequency 100,000 is consequently 4 metres only. In sea water $\nu=0\cdot013$ that is $\nu^1=0.0325$, and $c=1.5\times10^5$ cms./sec., whence $l=3\cdot9\times10^4$ kilometres at a frequency of 1000 ($\lambda=150$ cms.), and $l=3\cdot9$ kilometres at a frequency of 100,000 ($\lambda=1.5$ cms.). It is thus evident *the attenuation of sound-waves in sea water due to viscosity and heat losses is almost negligible compared with the attenuation at corresponding frequencies in air.* This accounts to some extent for the relatively large ranges of transmission observed under the sea compared with those in air for the same amount of sound energy at the source. A small charge (9 oz.) of guncotton ex-

[1] G. W. Pierce has shown experimentally that CO_2 becomes opaque to sound-waves at a frequency of 2×10^6 p p s

ploded *under water* can be detected (and recorded by an Einthoven galvanometer) at 40 miles (*see* Wood and Browne, *Phys. Soc. Proc.*, 1923). It is extremely improbable that such a range could be obtained in air. This comparison is of course only of a rough nature, for the wave form and the initial "amplitudes" would not be the same in the two cases. There is ample evidence to show, however, that the attenuation of bell sounds and other noises under water is less than in air. On account of other factors (nature of sound sources, homogeneity of medium, etc.) a strict comparison is somewhat difficult. *Attenuation by scattering in a heterogeneous medium* may be a serious factor in regard to loss of range in signalling by sound-waves. Tyndall found that a homogeneous atmosphere, clear or uniformly foggy, transmitted a sound signal to far greater distances than a "patchy" atmosphere containing masses of air at different temperatures, wind eddies, etc. Similarly when sound travels through water it may be seriously interrupted if it meets with a mass of bubbles. The sound of a ship's propeller does not pass very well through the bubbly water in the wake. Air bubbles in the sea may therefore be a serious cause of attenuation, the effects of viscosity and heat conduction being relatively small.

Sound Absorption in Narrow Tubes and Cavities. Porous Bodies.—When sound-waves fall on certain bodies which may be regarded as a mixture of solid and gas, *e.g.*, cork or felt, it is found that a large proportion of the incident energy is absorbed due to viscosity and heat conduction. The influence of these factors is enormously increased on account of the large surface of solid matter in contact with the vibrating gas particles. Viscous forces are increased at the surface of the solid, and the latter serves also as an effective means of reducing the temperature fluctuations in the compressed gas, *i.e.*, the compressions and rarefactions are no longer adiabatic. Rayleigh has shown theoretically (*Sound*, Vol. II, p. 331) that the attenuation of sound-waves in a narrow tube of circular section is proportional to the square root of kinematic viscosity ν^1, and the frequency N, and inversely proportional to the radius of the tube. Porous materials like felt, wool, cork, etc., are effective sound absorbers, and are used to reduce reverberations in auditoriums.

RECEPTION OF SOUND

The manner in which sound-energy is abstracted from the medium carrying the sound-waves is dependent on a wide variety of circumstances and each case must be treated accordingly. In the first place the choice of a receiver must depend on the medium of transmission—a receiver suitable for air being generally quite unsuitable under water or in a solid medium. Again the selection of a receiver will depend on the frequency and wave form of the vibration—sounds of frequencies 500 or 50,000, or a single explosion impulse, requiring entirely different treatment. If the sound-wave is employed in long-range signalling it is important that the receiver should be efficiently designed and tuned to the incoming sound, in order to obtain maximum response to weak signals. Distortion of wave-form in this case may be of secondary importance. On the other hand, if it is required to obtain a faithful record or reproduction of the sound-wave, energy considerations are relatively unimportant whereas an accurate reproduction of the wave-form is vital. In this connection we have to distinguish between resonant and non-resonant receivers. As a general rule a resonant receiver is employed where maximum sensitivity and efficiency are required, whilst a non-resonant receiver is used for faithful recording or reproduction of the sound.

All forms of sound-receivers involve the introduction of some obstacle into the path of the sound-waves, this obstacle either partaking of, or otherwise influencing, the motion of the particles of the medium, or responding in some way to the pressure variations on its surface. Energy may be lost due to reflection and reradiation from this obstacle, but in a good receiver a moderate amount of sound-energy is transferred from the medium and converted into a form convenient for observation. It is often desirable to transform the mechanical vibrations of the medium into another type of vibration or into some other form of energy. For example, longitudinal sound-waves passing through the air from the mouth of a speaker fall on the diaphragm of a telephone transmitter which is set into transverse vibration. This transverse vibration controls electrical energy which is transmitted to a distant diaphragm receiver and reconverted into mechanical energy in a form suitable for transmission to the ear. Many well known forms of sound-recording apparatus (*e.g.*, Webster's *Phonometer*, Millar's *Phonedeik*, and the Hilger *Audiometer*) employ a diaphragm receiver with some optical means of indicating and recording the transverse vibrations. Other forms, exemplified by magnetophones, microphones, piezo-electric receivers, condenser microphones, etc., involve the conversion of mechanical into electrical energy. Sound-vibrations may also be observed by means of such devices as optical interferometry and sound shadow photography or by means of manometric and sensitive flames. Metrical forms of receiver such as the Rayleigh disc and the sound-radiometer (measuring radiation pressure of sound-waves) form another class, which might also include the various "phonometers," the hot-wire microphone, and piezo-electric receivers. The amplification of received sounds by mechanical devices, "mechanical transformers," mirrors, trumpets and resonators, or by electrical means, microphone and valve amplifiers, must also be considered. In certain cases special devices are required, as in sound-reception under water (hydrophones) or in the detection of sounds travelling through the ground (geophones). The above remarks will be sufficient to show the difficulty of attempting a comprehensive classification of sound-receivers. In what follows we shall deal with the more important types, some of which have already been mentioned.

The Ear.—*Sensitivity and Audible Limits.*—By far the most important and most universal receiver of sound is the ear. This "organ of hearing" has a marvellous range of frequency and sensitivity; it can perceive vibrations of frequency varying from 20 to 30,000 cycles/sec., and can detect a sound of amplitude less than 10^{-8} cm. whilst it is not destroyed by a vibration having an amplitude a million times as great. The ear with its associated nerve endings has also remarkable powers of analysis. It can distinguish one complex sound from another and can "listen intelligently" to a number of different sounds at the same time. For a complete description of the complicated structure of the ear, reference should be made to text books of physiology or anatomy. Briefly, it consists of a device which brings the waves of sound to act on a terminal expansion of the auditory nerve. This device is divided anatomically into three parts, the external ear with the auditory meatus, the tympanum and the internal ear. The external ear in the case of the lower animals is very movable, presumably to assist in sound-location. This function in man is rudimentary so that he can hear almost normally with his ears cut off. The external ear is separated from the tympanum by the "drum" of the ear or membrane tympani, which is set in vibration when sound-waves fall upon it. These vibrations are transmitted with diminishing amplitude but increased pressure by a chain of bones (malleus, incus and stapes) acting as a system of levers, to the fluid (perilymph) in the internal ear. The vibrations travel through the perilymph from the vestibule and the "oval window" up the turns of the cochlea and ultimately to the basilar membrane thus affecting the haircells and the ends of the auditory nerve. Many theories, notably the resonance Theory of Helmholtz, have been proposed to explain the function of the various parts of the ear, in particular the cochlea and the basilar membrane (with the "rods of Corti" and the haircells), but none appears to be really satisfactory. It is certain, however, that the more highly developed the cochlea the more perfect is the hearing of an animal. This is shown in birds and mammals which have a far more perfect cochlea than is found in reptiles and fishes.

Sensitivity of the Ear to Intensity and Frequency Variation.—The relation between sensation (loudness) and stimulus (intensity) applicable to all sensations, is generally expressed by *Weber's law*—"The increase of stimulus necessary to produce the mini-

mum perceptible increase of sensation is proportional to the pre-existing stimulus." From this law Fechner derived the relation $S=k \log E$ or $\partial S/\partial E=k/E$, where S is the magnitude of the sensation, E the intensity of the stimulus and k a constant. The "law" obviously approximates to the truth, for the sensitiveness of the ear $\partial S/\partial E$ diminishes rapidly with increase of the total intensity E of the sound. Feeble sounds which are easily heard at night when E is small, cannot be distinguished from the general noise in the daytime when E is much greater. Wood and Young (*Proc. Roy. Soc.*, A. 100, p. 264 and p. 266, 1921), in judging equality of two sounds of the same pitch, remark that under favourable conditions it was possible to distinguish a difference of intensity of 10%. A similar conclusion was reached by V. O. Knudsen (*Phys. Rev.*, 21 Jan. 1923). Measuring the "intensity sensitivity" of the ear $\delta E/E$ where δE is the least perceptible difference of energy and E the total energy of the tone, Knudsen found $\delta E/E$ to be about 0·10 for moderate and large intensities E, but increased to the limiting value of unity as the intensity decreased to the threshold value E_o (the minimum energy of audibility) To include this region of very feeble intensities Knudsen proposed a modification of the Weber-Fechner law, namely, $\delta E/E=k+(1-k)\ (E_o/E)^n$ where $k=0{\cdot}10$ app. and n varies somewhat with frequency, being 1·65 for 200 cycles/sec. and 1·05 for 1,000 cycles/sec , nevertheless at the same loudness level *e.g.*, 10^4E_o, $\delta E/E$ is nearly independent of frequency. More recently R. R. Reisz (*Phys. Rev*, 31, May, 1928) has found that $\delta E/E$ lies between 0·05 and 0·15 according to frequency. He found also that $\delta E/E$ is a minimum at 2,500 p p.s —this minimum being more sharply defined at the smaller sound-intensities This frequency corresponds to the region of greatest absolute sensitivity of the ear Fig. 12 indicates the range of the average human ear with regard to both intensity and frequency. The upper curve gives the sound-pressures (root mean square) which produce a sensation of *feeling*, and serves as a practical upper limit to the range of auditory sensation (Wegel, *Bell System Tech. Journ* , 1, Nov. 1922) whilst the lower curve indicates the pressures at the threshold of audibility. It will be seen that the ear is most sensitive in the region of frequency 500 to 5,000 p p sec. The range of intensity (proportional to square of pressure) appreciated by the ear in this range is of the order 10^{12}. The smallest detectable pressure-amplitude is of the order 10^{-3} dyne/cm.^{2}, *i.e.*, 10^{-9} of atmospheric pressure, corresponding to a displacement-amplitude of the order of 10^{-9} cm Knudsen, Fletcher and Reisz independently conclude that near a frequency of 2,000 the ear can distinguish, under favourable conditions, from 300 to 400 gradations of loudness between the threshold of audibility and the threshold of feeling (a painful intensity 10^{12} times as great)—each step being recognisable by the ear as just perceptibly louder than the one before it.

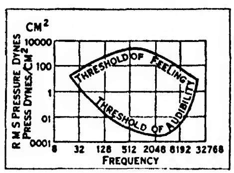

FIG 12

Audible Limits of Frequency.—The lower and upper limits of frequency for tones audible to the human ear vary according to different observers A very good average range of frequency may be taken as 20 to 20,000 cycles/sec. Very high and very low pitched sounds of great intensity are felt rather than heard The ear loses its power to discriminate variations of pitch at very high frequency. The frequency range employed in music extends from about 40 to 4,000 cycles/sec. When two notes within the range 500 to 4,000 cycles/sec. are sounded alternately, the ear can detect a difference of frequency of about 1 in 300. When the two notes are sounded together the discrimination is greatly improved—a frequency difference of one in 20,000 being readily discernible by "beats" (*see* p. 6). Kohlrausch demonstrated experimentally that the sensation of pitch may be excited even with so few as two vibrations.

Perception of Direction. Binaural Audition.—The direction of a sound proceeding from the right or the left is readily determined with fair accuracy, but there is little difference observable between a sound approaching from behind or ahead. For high pitched sounds of short wave-length these directional effects might be explained by the difference of intensity of the sound reaching the two ears, since the head acts to some extent as a screen to the ear which is more remote from the source of sound. When the wave-length of the sound exceeds the perimeter of the head, however, the intensity difference must be very slight and we must look for another explanation of the directional effect. Rayleigh (*Sound*, Vol II , p 440) who has examined this question carefully, arrived at the conclusion that the perception of direction is dependent on the relative *phase* of the sounds as they reach the two ears, a small difference of phase being sufficient to indicate the required direction. He found that if the same tone be led by different paths to the two ears, the sound could be made to appear to come from the right or the left at will, by adjusting the path-lengths and consequently the relative phase. The origin of the sound was always attributed to that side on which the phase is in advance (by less than half a period). No explanation of this effect has yet been given

Pressure of Sound-Waves.—*Radiometers* —Sound-waves, like light-waves, exert a slight pressure on any surface upon which they fall, and radiometers for measuring sound-intensity have been constructed on this principle Rayleigh (*Phil. Mag* , 10, 1905) has determined this pressure on theoretical grounds, but a more simple treatment due to Larmor will suffice here. Plane-waves are incident on a perfectly reflecting wall free to move, the wall being pushed with velocity v to meet the advancing sound-waves of velocity c and mean energy density E (*see* p 28). The total energy density in front of the wall, if stationary, would be $2E$ due to the incident and reflected trains of waves. The length of the wave-train incident per second on the advancing wall is $(c+v)$ this being compressed during transmission into a length $(c-v)$ due to the approach of the wall. The energy density in the reflected-wave is therefore increased in the ratio

$$(E+\delta E)/E=(c+v)/(c-v)=1+2v/c,$$

that is, $$\delta E=E\ 2v/c.$$

The increase in the total energy in the region of length c in front of the moving wall is consequently $c\ \delta E$, and this must inevitably be due to the work done by the wall in compressing the radiation. If P is the radiation pressure, the work done by the wall per second is Pv, whence $Pv=c{\cdot}\delta E=E\ 2v$, that is, $P=2E$, *the mean radiation pressure being equal to the energy density in the medium in front of the wall.* If the wall is a perfect absorber there will be no reflected-wave and $P=E$ Now the intensity of the sound is equal to the energy density×the wave-velocity c (*see* page 22) Provided therefore that the radiation pressure can be measured, and the reflection characteristics of the wall can be determined, we have here an absolute method of measuring sound-intensity. Radiometers for measuring the intensity of high frequency sound-waves under water have been constructed on the above principle by Langevin, Wills, Boyle and others. Boyle (*Proc Roy. Soc* , Canada, 1925) constructed torsion pendulums for use with high frequency quartz oscillators under water. The pressure of the "ultra sonic" radiation on the pendulum vane causes a deflection which is reduced to zero by a torsion head. This gives a measure of the twisting moment and consequently the radiation pressure Comparative measurements with such radiometers confirm the theoretical deduction that the radiation pressure is proportional to the energy density. All absolute measurements of radiation pressure must, of course, make allowance for diffraction at the edge of the reflecting vane. Using the radiometer method, Boyle measured the energy output of high frequency quartz oscillators and the reflection and transmission coefficients of various materials under water. Torsion radiometers have similarly been used to measure sound-intensity in air (Altberg, *Ann. d Phys.*, 11, 1903) They are only of value, however, in cases where the sound-intensity is very great.

Rayleigh Disc.—A device which is often used in sound-in-

tensity measurements is due to Rayleigh (*Sound*, Vol. II., p. 44). A delicately suspended disc (a small mirror about ½-in. diameter) will tend to face a stream of air (or other medium) flowing past it, whether the flow be direct or alternating. The torque M on the disc tending to diminish θ, the angle which the normal of the disc makes with the stream, is given by $M = \frac{4}{3}\cdot \rho a^3 v^2 \sin 2\theta$, "$a$" being the radius of the disc, ρ the density of the medium and

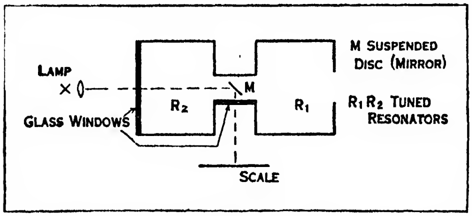

FIG. 13

v the velocity of the stream. If the stream be alternating instead of steady, it is only necessary to employ the mean value of v^2. The maximum torque is obtained when $\theta = 45°$. A light galvanometer mirror suspended on a fine quartz fibre provides a very sensitive arrangement, particularly when used inside a double resonator (*see* fig. 13) tuned to the frequency of the sound it is desired to measure. When accurately tuned to the sound falling upon the open end of the resonator R, the instrument can be used to compare the intensities of sounds of the same frequency. The sensitiveness is comparable with that of the ear. The deflections, if small, are proportional to the square of the particle velocity in the undisturbed field. It is important that the diameter of the disc should be small compared with the wave-length of the incident sound. As the double resonator and disc system is very sharply tuned, a large number of instruments would be required to cover a moderate range of frequency and intensity. A disc mounted in the mouth of a single resonator of continuously variable tuning is more generally useful, but is less sensitive.

Resonant Receivers.—When the incoming sound-waves have a predominant frequency it is clearly advantageous to "tune" the receiver to obtain maximum sensitivity. The tuning of a receiver, *e.g.*, an air cavity or a diaphragm is similar to the tuning of a sound transmitter. In many electrical cases the same device may serve either as a transmitter or a receiver, *e.g.*, a telephone earpiece (magnetophone), a Fessenden electro-magnetic oscillator or a piezo-electric oscillator. Under these circumstances it is possible for the tuning to be very exact. A resonant air cavity develops a relatively large amplitude of vibration at its mouth, this amplitude being considerably in excess of that in the surrounding medium. The sound-field near such a resonator is affected by its behaviour as a secondary source, the energy which the resonator emits being drained from the other parts of the sound-field. It can be shown that the area of wave-front from *which energy is extracted* (*and re-radiated*) by a small resonator is λ^2/π where λ is the wave-length of the incident sound to which it is tuned. This area may be considerably greater than the area s of the resonator, the energy amplification being $\lambda^2/\pi s$. In actual resonators, however, only a part of this energy is re-radiated, the remainder being absorbed. The latter portion is partly dissipated in viscous damping and partly converted into a useful form, *i.e.*, is utilised in operating a detector, such as a microphone, or a magneto-phone, or in deflecting a mirror. The efficiency of the receiver is dependent on the proportion of the total energy which is usefully absorbed. Absorption of energy involves damping. The receiver is inefficient if it is underdamped, little or no energy being absorbed, or if it is over-damped, too much or all the energy being absorbed. If the receiver is underdamped it re-radiates too large a proportion of the received energy back into the medium. Overdamping reduces the sharpness of resonance and consequently reduces the area from which energy is obtained, the main advantage of tuning being lost. The most efficient receiver lies between these extremes, *i.e.*, the energy absorbed is equal to the energy re-radiated. In other words, in an efficient tuned receiver the damping due to the medium must be equal to the internal damping in the receiver. It is of course, equally important that the internal damping must be *useful* damping, *i.e.*, the absorbed energy must be used efficiently. Thus if the receiver is electro-magnetic (a telephone receiver) it is important that the ratio of *motional* impedance (measured electrically) to total electrical impedance should be as great as possible. A solid resonator such as a tuned metal diaphragm in air is necessarily inefficient, for a large proportion of the incident energy is reflected or scattered from its surface as from a rigid obstacle. The energy re-radiated to the medium due to the vibration of the diaphragm is extremely small.

Mechanical Transformers.—It is sometimes desirable to convert an oscillation of large displacement and low pressure to one of small displacement and high pressure; a mechanical process analogous to the electrical transformation of a large alternating current at low voltage to a small current at high voltage. Hahneman (*Inst. Radio Eng. Proc.*, II., Feb. 1923) has employed this principle in the design of sound-transmitters and receivers for use under water. As a rule, in such apparatus, one part of a vibrating system is actuated in air whilst another, coupled to it, vibrates in contact with water. In transferring vibratory pressure from air to water a "step-up" pressure transformer is required, and conversely. For this purpose Hahneman employs a mechanical lever of a novel type, the ordinary pivoted lever and link system being useless at even moderate frequencies. He also considers it desirable, as far as possible, to separate the mass and spring factors of the vibrating system, like a weight on a spring, rather than a combined mass and spring as in the prong of a tuning fork. The lever principle is as follows: Two masses m and M are connected as in fig. 14a by a spring of stiffness s. At resonance, neglecting energy radiated, the system will vibrate about its centre of gravity, the amplitudes a and A of m and M being inversely proportional to the masses, i.e., $a/A = M/m$. The spring will be undisplaced at the centre of gravity of the system, *i.e.*, at some point O such that $l_m/l_M = M/m = a/A$.[1] The natural frequency of the two parts on opposite sides of O is

$$N = \frac{1}{2\pi}\sqrt{s\left(\frac{1}{M}+\frac{1}{m}\right)}.$$

In applying this principle to under-water sound transmitters, Hahneman replaces the diagrammatic helical spring by an elastic rod or tube, as in fig. 14b, which combined with the loads m and M tunes to the required frequency. The masses may be pistons or diaphragms suitable for electro-magnetic excitation and for the transmission of vibrations to the water (*see* fig. 3, plate, and *Technical Applications: Sound-Signalling*). S. T. Williams (*Journ. Franklin Inst.*, Oct. 1926) refers to the

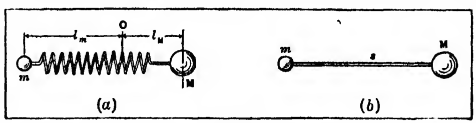

FIG. 14

use of mechanical "transformers" in the design of a gramophone sound-box.

Diaphragm Receivers.—Unless special precautions are taken to ensure sufficient damping, the diaphragms of microphone transmitters and electro-magnetic receivers used in telephony will have marked resonant frequencies at which they are abnormally sensitive. For speech reception such resonances are undesirable. When maximum sensitiveness is required at one particular frequency it is a great advantage, however, to use a diaphragm tuned to that frequency. Tuned diaphragms with

[1] The "mechanical advantage," "velocity ratio" and "mechanical efficiency" of this alternating lever are analogous to those for static levers.

either microphone or magnetophone (electro-magnetic) attachments have been used extensively in under-water signalling. Lamb has shown theoretically that for diaphragms having the same frequency in water the amplitude at resonance is inversely proportional to the area of the diaphragm. When an additional damping factor, such as a granular microphone, is introduced there is a "best size" of diaphragm, increasing with increase of the added damping. (*See* Powell, *Phys. Soc. Proc.*, Feb. 1925.)

Electro-magnetic Receivers.—The vibrations of a diaphragm may be employed to excite currents in an electrical circuit embracing or lying in a magnetic field. The iron diaphragm of a telephone earpiece by its vibrations varies the magnetic flux passing through a coil and consequently induces alternating currents of the same frequency as the sound vibrations falling on the diaphragm. Similar results are obtained when an iron reed clamped at one end is set into vibration by sound-waves falling on a stiff cone attached to the free end of the reed. In an alternative form the diaphragm or reed, which now may be of non-magnetic material, is attached rigidly to an annular coil of wire which lies in a strong magnetic field. Vibrations of the diaphragm and coil induce currents in the latter of the same frequency as the sound-waves. Telephone, microphone, and loud speaker movements are constructed on these principles. Such instruments can also be used to generate sound-waves by supplying the coil with alternating current of the required frequency. Diaphragm and reed receivers have usually marked resonant frequencies, the sharpness of resonance increasing with the load attached to the diaphragm (*see* p. 8). They may if required be used as "non-resonant" receivers, provided their natural resonances are reduced by damping or are far removed in frequency from that of the sound it is desired to receive. The efficiency of electro-magnetic receivers is determined from observations of damping and motional impedance (*see* p. 9).

Resonant Air Cavity. *Hot-Wire Microphone.*—One of the most sensitive and metrical forms of resonant receiver for sounds in air, is a Helmholtz resonator fitted with a hot-wire microphone. In the hands of Tucker and Paris (*Phil. Trans.*, 221. 1921) this combination has proved of great value in its technical applications and as a laboratory instrument for sound-measurement It consists essentially of an electrically heated grid of fine platinum wire (0·0006 cm. diameter) placed in the neck of a Helmholtz resonator, or in the second neck of a "double-resonator" such as that shown in fig 13. The oscillating air currents in the neck at resonance cool the hot grid, the extent of this cooling being measured (by a Wheatstone's bridge) as a change of electrical resistance. This resistance-change is a measure of the *intensity* of the sound. The instrument is calibrated by observing the cooling produced by steady air streams of known velocity. The sensitivity increases with increase of heating current. The tuning of the microphone and resonator is fairly sharp; in a typical example the response fell to one tenth of its maximum by "detuning" 7%, *i e.*, $n/p = 1 \pm 0{\cdot}07$. In common with other forms of Helmholtz resonator receivers, therefore, a series of instruments is required to cover a moderate range of frequency. The hot wire-microphone increases in sensitiveness towards the lower frequencies (say 100 per second); its upper limit being about 500 to 1,000 cycles/sec. The device has proved extremely useful in measurements of intensity and distribution of sound, particularly for testing trumpets, lenses, mirrors and other sound-concentrating devices and also for investigating the reflection and diffraction of sound-waves generally. Used in connection with resonators of very low frequency the hot-wire microphone proved of great value during the war in detecting and locating the positions of enemy guns. (*See* p. 22.)

Non-Resonant Receivers.—The ideal non-resonant receiver, equally sensitive at all frequencies, is not known. The best approximations aim at uniform sensitivity over a limited range of frequency—the better the receiver the more extended the range. Non-resonant receivers are, as a general rule, considerably less sensitive than the resonant type at a particular frequency but have a good average sensitivity over a wide range. A good example for use in air, is *Wente's condenser microphone* (*see* MICROPHONE) which employs a tightly stretched diaphragm of high natural frequency and a considerable amount of air-damping. *Piezo-electric receivers* are perhaps the best examples of the non-resonant type, for their natural frequencies are always very high (10^4 to 10^6). Rochelle salt, quartz and tourmaline suitably mounted give electrical effects which are an extremely faithful counterpart of the incident sound vibrations, over the whole sonic and a considerable region in the super-sonic range of frequencies. As Boyle, Langevin and others have shown, however, such receivers are most suitable for use in a medium like water. In air they are extremely insensitive, although Nicholson has obtained fairly good results with Rochelle salt receivers (*see* also p. 12). *A multi-resonant receiver* with a number of fairly flat overlapping resonance peaks, due to the various components which make up the receiver, could be designed to have a fairly uniform high sensitivity over a wide frequency range. The principle has been applied with success to gramophone recorders and reproducers (*see* p. 34). (*See* GRAMOPHONE.)

Sensitive Flames are very convenient detectors of high frequency sounds in air. A long narrow gas flame, issuing from a "pinhole" orifice and adjusted to the point of flaring, becomes unstable, flares and shortens when high pitched sounds fall upon it. The action of such flames and sensitive jets of gas is discussed in Tyndall's and Rayleigh's *Sound.* The flame is commonly used to demonstrate the presence of nodes and antinodes in stationary-waves of high frequency, and to indicate the position of the sound focus of a concave reflector

Under-Water Receivers. *Hydrophones*—During recent years rapid progress has been made in sound-signalling under water, and the allied navigational problems of sound-ranging, echo-depth-sounding, submarine detection, etc. The earliest and most simple of all subaqueous receivers was known as the "Broca" tube which consisted of a long metal tube with a thin metal capsule fitted with a diaphragm stretched over the end. A similar, but less resonant, device employs a thick-walled rubber bulb in place of the diaphragm. The arrangement is fairly sensitive but is very inconvenient in use—observation at a distant point (on a ship, or at a shore station) being almost impossible. Electrical devices have replaced such tubes, both on the grounds of sensitiveness and convenience. Microphonic and electro-magnetic devices, attached to diaphragms and enclosed in watertight cavities have proved very satisfactory. Such subaqueous sound-receivers are generally known as *hydrophones*. Generally speaking, the diaphragms for use under water are much more massive than those used in air, on grounds of strength, durability and efficiency. A microphone or magnetophone (an electro-magnetic device like a telephone earpiece) attached to a metal diaphragm and immersed in water forms a system which may have one or more resonant frequencies. Such a receiver is therefore suitable where sensitivity is more important than "faithfulness"—*i.e*, for reception of under-water signals of a definite frequency, a suitably tuned diaphragm and microphone are desirable. Comparatively non-resonant receivers have been constructed of thick rubber—the sensitivity being correspondingly low—these being found valuable in discriminating between various types of ships' noises under water. Receivers of the diaphragm type are essentially *pressure receivers.* Another type of receiver known as the "light body" *displacement receiver* (*see* Wood and Young, *Proc. Roy. Soc.*, 100, 1921) is essentially responsive to displacement or velocity of the water particles and is relatively insensitive to pressure. The two types may be compared with voltmeters and ammeters as electrical pressure and current measuring devices (*see* Drysdale in *Mechanical Properties of Fluids*, p. 293. *See* also Bragg, *World of Sound*, pp. 161–177). Reference has already been made to the use of piezo-electric devices for production and reception of high frequency sounds under water (*see* p. 12).

Geophones.—A simple device first used to detect enemy tunnelling operations in the war, serves to detect sound pulses travelling through the ground. It consists essentially of a cylin-

drical wooden box of about 3 in. diameter and 2 in. deep, divided into three compartments by two mica discs. The space between the discs is filled with mercury, whilst the two air compartments are connected to the ears by stethoscope tubes. The "geophone" is laid on the ground and vibrations are detected by the relative motion of the box and the mercury. The air spaces are alternately expanded and compressed, the sound pulses being conveyed to the ears via the tubes. Two such instruments, one compartment of each connected to each ear, give a sense of direction as in binaural audition.

Directional Reception.—This may be regarded as the converse of directional transmission of sound which we have already considered (*see* p. 18). We have referred also to the directional properties of a vibrating diaphragm when free to radiate, or receive, waves on both sides (*see* p. 29), and to the perception of direction by a pair of ears (*see* p. 29). These principles have been developed both for air and under-water reception of sound.

Diaphragms.—A single diaphragm or membrane mounted in a heavy annular ring and carrying a microphone at its centre forms a bi-directional receiver. A section of such a receiver is shown in fig. 15 (a) with its "figure of 8" polar curve of sensitivity. The microphone is unaffected when the sound pressure falls symmetrically on both sides of the diaphragm, whilst the response is a maximum when the sound-waves fall broadside on the diaphragm. The mode of action is discussed by Wood and Young in a paper dealing with the Admiralty pattern of "Single Plate Direction Finder" for use under the sea (*Proc. Roy. Soc.*, 100. 1921). A disc of tightly stretched parchment mounted on a ring, with a light "button" microphone at the centre, gives excellent results in air. By means of a suitable screen ("bias" or "baffle plate") on one side of such a diaphragm it is possible to obtain a uni-directional instrument having the polar curve of sensitivity shown in fig. 15 (b). This baffle plate, when used under water, consists of a compound hollow disc containing air and lead shot (or some other suitable damping material to prevent excessive vibration of the walls of the cavity). Its exact function is somewhat complicated, but no doubt it acts partly as a sound screen and partly as a phase-shifting device with respect to the sound vibrations reaching the diaphragm.

Binaural Receivers.—The principle of binaural listening expounded by Rayleigh has been extended to the use of artificial "ears" which can be made very sensitive to a given type of sound and can be arranged at any convenient distance apart or with any orientation with respect to the source of sound. The principle has been applied to aeroplane and to submarine location (see *Mechanical Properties of Fluids*—"Submarine Listening," Drysdale). For example if two similar receiving trumpets are connected by equal lengths of tube to each ear, the trumpets

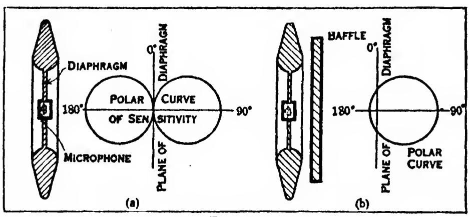

FIG. 15

being mounted a fixed distance apart on a rotatable platform, it is possible to locate a source of sound such as an aeroplane with considerable accuracy. The trumpets amplify the sound received by the ears and the directional accuracy is increased by increasing the distance apart of the trumpets. As the platform is swung round, the path-difference of the sound reaching the two ears diminishes on one side and then increases on the other, giving the impression of the sound crossing from one ear to the other. At the point of "cross-over", *i.e.*, of binaural balance, the line joining the trumpets is at right angles to the direction of the source. The same principle can be applied to a pair of under-water receivers. As an alternative to rotation of the line of the receivers it is often more convenient to vary the path-length to the two ears, the difference of path, relative to the distance apart of the receivers, being a measure of the "rotation" required to bring them symmetrical with respect to the source. This is known as the *binaural compensator* principle. The principle has been extended to *multiple receivers*, that is, to a considerable number of similar receivers equally spaced on a long base line. Instead of rotating the whole base line, a suitable rotary compensator is provided, the direction being indicated at the point of binaural balance. The directional properties of multiple receivers are the same as for corresponding multiple sources (*see* p. 31). In the case of electrical receivers the binaural method may be replaced by the *Sum and Difference Method*—the effects at the ear being due to the receivers assisting or opposing each other. The sound received by the ear is a maximum or a minimum respectively, when the normal to the line of the receivers is in the direction of the source of sound.

Receivers of Large Area.—Just as a directional source of sound is obtained by using a vibrating surface of large dimensions compared with a wave-length, so a receiver becomes increasingly directional as its dimensions increase. The piezo-electric quartz directional transmitter used by Boyle and Langevin serves equally well as a directional receiver. Similarly, large trumpets, mirrors and other focusing devices exhibit directional properties with increasing size or with increase in the pitch of the sound (*i.e.*, with diminishing wave-length). Reference has already been made to the reflection which takes place at the open end of a cylindrical pipe or a trumpet acting as a sound receiver. The extent of this reflection diminishes, and the trumpet becomes a more efficient receiver, as the size of the opening increases, provided the length of the trumpet is always large. A parabolic mirror converges the sound energy towards a focus, but it must not be assumed that this is in any way an "optical focus," although it approximates more and more to it as the wave-length of the sound diminishes. A watch tick, the sharp crack of a pistol or an electric spark may be focused very effectively by a mirror of moderate dimensions. The increase of loudness due to curvature depends on the area of the reflecting surface, from which disturbances of uniform phase arrive, as compared with the area of the first Fresnel's zone of a plane reflector in the same position. If the "focal length" of the reflector is considerable and λ is not small, the first Fresnel zone is fairly large, therefore for a reflector of moderate dimensions there is little to be gained by making it concave.

Diffraction Disc Method.—On p. 26 reference was made to the fact that the sound intensity at a point on the axis of a circular obstacle placed normal to a beam of sound is as great as if the obstacle were not present, *i.e.*, the sound "shadow" of the disc has, to quote the optical analogy, a *bright spot* at the centre. A microphone, tuned to the frequency of the incident sound, and placed at a suitable point on the axis of such a disc forms a very sensitive directional receiver, the response being a maximum when the sound is normal to the disc. Discs 20 feet or more in diameter have thus been used in combination with resonant hot-wire microphones as an extremely accurate and sensitive means of locating distant sources of sound in air.

The location of sounds of an explosive nature by the use of a number of receivers on measured base lines is described in the section on Sound-Ranging (*see* p. 35).

Sound-Analysis and Recording.—It is sometimes desirable to determine the nature of a complex sound, more particularly in regard to the relative amplitudes and the frequencies of the component tones. The frequency analysis is relatively simple, but the amplitude measurement is much more difficult. There are numerous ways of determining the various frequencies present in a sound-wave, *e.g.*, we have already referred to the use of Helmholtz resonators for this purpose. In frequency analysis it is more convenient to employ resonators of continuously variable frequency, *e.g.*, by varying the volume of the resonator by

means of a sliding piston or a water column. Resonance in such a receiver may be detected in a number of ways, *e.g.*, by ear, optical devices, Rayleigh disc, or some form of microphone, such as the hot-wire microphone. The use of resonators, whilst giving reliable information in regard to the frequencies of the tones present in the sound-wave gives only approximate information regarding the relative intensity of these tones.

Numerous instruments have been devised which are described as intensity or sound-energy-meters, many of which give indications in some way related to sound-intensity. In no case, however, is the device universally applicable to all frequencies and intensities. Many attempts have been made to record wave-forms of sound by means of diaphragms and stretched membranes. The movements of a vibrating diaphragm excited by sound-waves have been recorded in various ways, mechanically, optically and electrically. Mechanical recording is exemplified in the gramophone, where a needle attached via a lever mechanism to the diaphragm traces the wave-form on a revolving disc or cylinder. (*See* GRAMOPHONE.) Optical methods have been very commonly used, *e.g.*, in Kenelly's analysis of the motion of telephone diaphragms, in Webster's phonometer, in Millar's phonodeik and in the Hilger audiometer. In all these examples a small mirror reflects the vibrations of the diaphragm on to a moving photographic film. Electrical methods involve the use of a microphonic or electro-magnetic device which responds to the vibrations of the diaphragm, the corresponding electrical oscillations being recorded by means of some form of oscillograph, *e g.*, the Duddell strip, the Einthoven string or the cathode ray oscillograph (*see* INSTRUMENTS, ELECTRICAL; *see also* Irwin, *Oscillographs*). The majority of such diaphragm receivers are subject to resonances at certain frequencies with the result that the record is a distortion of the actual wave-form, the distortion being greatest in the neighbourhood of the resonance frequencies of the instrument. The defect may be exaggerated or partially compensated by the use of a cone or trumpet to collect the sound and increase the amplitude of the diaphragm Great care is necessary in the choice of a receiver, and recorder, for a particular type of sound, otherwise a number of factors may contribute to the distortion. Thus in electrical recording, distortion may be caused by resonance in the diaphragm, the microphone mounting, the trumpet or cone collector, the electrical circuit, and in the oscillograph. In addition to this, there may be distortion introduced solely on account of the dimensions of the receiver relative to the wave-lengths of the various components of the sound As we have seen, a receiver which is large compared with a wave-length exhibits directional properties depending on the ratio λ/D (where D is the diameter of the receiver). One of the best non-resonant receivers developed during recent years is *the stretched diaphragm condenser microphone* of Wente (*Phys. Rev.* 10 39. 1917). This was specially designed for sound-measure-

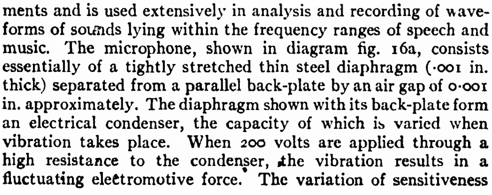

FIG. 16

ments and is used extensively in analysis and recording of wave-forms of sounds lying within the frequency ranges of speech and music. The microphone, shown in diagram fig. 16a, consists essentially of a tightly stretched thin steel diaphragm (·001 in. thick) separated from a parallel back-plate by an air gap of 0·001 in. approximately. The diaphragm shown with its back-plate form an electrical condenser, the capacity of which is varied when vibration takes place. When 200 volts are applied through a high resistance to the condenser, the vibration results in a fluctuating electromotive force. The variation of sensitiveness of such a microphone with frequency is indicated in fig. 16 b. It will be seen that the output in milli volts (10^{-3} volt) per dyne/cm.² is fairly constant over a frequency range 500 to 5,000 cycles/sec. The microphone is very insensitive when compared with other, more familiar, types (granular and electro-magnetic) but its freedom from resonance over a wide range of frequency renders it most valuable for purposes of sound analysis The lack of sensitiveness can easily be remedied by the use of a "distortionless" valve-amplifier (resistance-capacity coupled valves) Crandall (Bell. Syst. *Tech. Jour.*, 4. 1925, p. 587) employed Wente's condenser microphone in conjunction with such a valve amplifier to record speech sounds. A well designed amplifier will give practically constant amplification over the range of speech frequencies and will give an output proportional to input The amplified e m f is recorded by means of an oscillograph which must itself be non-resonant over the range of frequencies to be recorded. With certain limitations a high frequency Duddell strip well damped may serve the purpose, or alternatively an Einthoven oscillograph with a critically damped fibre of silvered quartz may be used. Perhaps the most perfect form of sound recording system is one proposed by Sir J. J. Thomson, namely a piezo-electric crystal receiver used in conjunction with a cathode ray oscillograph. Such a combination was used by Keys (*Phil. Mag*, Vol. 42, 1921) in recording the pressure-time curve of an explosion-wave under water. The piezo-electric receiver has a very high natural frequency and is consequently non-resonant over a very wide frequency-interval which includes the audible range. The cathode ray oscillograph (*see* A. B Wood, *Proc. Inst. Elect Eng.*, Nov, 1925) is a perfect non-resonant recorder of electrical oscillations, having the same sensitivity at *all* frequencies from zero to the highest "radio" frequency. The combination may therefore be regarded as distortionless. The sensitivity for sounds of moderate intensity is, however, very small and amplification is necessary The faithfulness of reproduction is ultimately dependent on limitations of the amplifier.

Measurement of the Amplitude of a Vibrating Body.— W. H. Bragg has described a very simple and ingenious method of measuring the amplitude of a vibrating surface (*e.g*, of a diaphragm). A small mass supported by a spring is brought into contact with the vibrating surface and the fixed end of the spring displaced through a distance A until there is no longer "chattering" between the mass and the diaphragm. At the point where chattering ceases, the maximum acceleration of the diaphragm is just equal to that of the mass attached to the spring Thus if a and n and A and N represent the maximum amplitude and the frequency of the diaphragm and the spring respectively, we must have $an^2=AN^2$ or $a=AN^2/n^2$. Consequently if N is very small compared with n, A will be very large compared with a, in this way yielding a large "magnification" of the amplitude to be measured. As an example, if $n=1{,}000$ p p.s $N=1$ p.p.s. and $A=1$ cm., then $a=10^{-6}$ cm. The method permits of the measurement of very small amplitudes, the chattering being observed electrically. It is important of course to observe that the measuring device is sufficiently light so as not to interfere with the motion of the vibrating surface whose amplitude is required. Measurements of the amplitude of vibration of a diaphragm have also been made by making it one of the reflecting surfaces of a Michelson interferometer (Webster, *Nat. Acad Sci*, 5, p. 179, 1919). The displacement of the interference fringes, photographed in vibration as a wavy line, gives a measure of the amplitude in terms of the wave-length of light. Such a diaphragm then forms a standard source of sound. Known amplitudes of vibration may also be obtained by applying measured alternating voltages to piezo-electric crystals, provided resonance-frequencies (usually extremely high) are avoided. Rankine has described (*Proc. Phys. Soc*, Aug 1919, and Feb. 1920) a method of recording sound vibrations by means of variations in the *intensity* of a beam of light, the resulting film, of varying transparency, forming a convenient means for reproducing the original sound, using selenium or

other photoelectric cells. When a wave-form has been recorded by any of the methods indicated above, it may be analysed into a Fourier series (*see* p. 7) which gives the frequencies and relative amplitudes of the tones of which the sound is composed.

TECHNICAL APPLICATIONS

The past ten or fifteen years mark a period of considerable progress in the technical application of the principles of sound. It is proposed in what follows to deal with the more outstanding of these applications apart from those already mentioned in the foregoing sections. The exigencies of war stimulated the development of apparatus for detecting, identifying, and locating sounds at long ranges. Numerous forms of directional sound-receivers, sound-ranging and sound-signalling devices were realised and applied to urgent problems on land and sea. Since the war, the growth of radio-telephony and "broadcasting" has resulted in improved methods of reproducing sounds of audible frequency. The phenomena of piezo-electricity, discovered by Curie in 1880, have in the hands of Cady and others developed into a means of standardising mechanical and electrical frequencies over a range extending up to millions of vibrations per second. In this respect also improvements in tuning fork design have played an important part. A further application of piezo-electricity, initiated by Langevin and developed by Boyle, employs the supersonic oscillations of quartz in depth sounding at sea and in the echo detection of icebergs. At the other end of the frequency scale, Constantinesco has developed a system of power transmission through water-filled pipes, employing generators, motors, transformers and transmission lines closely analogous to the corresponding electrical devices. Such alternating mechanical systems are capable of dealing with large amounts of power in the form of low frequency pressure-waves. The elimination of objectionable resonance from gramophones and loud-speakers represents a marked degree of progress in the development of apparatus for reproducing speech and music. The study of the characteristics of speech and hearing, notably the work of the staff of the Bell Telephone Laboratory U.S.A., has greatly increased our knowledge of these subjects. The results have proved of great value in the improvement of telephone apparatus, microphones, electro-magnetic receivers, transmission lines, etc., and in the design of all forms of apparatus for recording or reproducing speech and music. In this connection also the introduction of the conception of acoustic impedance, as the analogue of electrical impedance, in dealing with complex acoustical systems has proved of great value. In a recent discourse before the Royal Aeronautical Society, Tucker has dealt with the problem of noise-reduction in aircraft, the deafening roar in the cabins of civil aircraft being a serious hindrance to commercial development. The general question of reduction of traffic noise is becoming increasingly insistent as an urgent practical problem still awaiting solution.

Reproduction of Sound.—The telephone (*q.v.*), the gramophone (*q.v.*) and the radio loud-speaker are among the most familiar types of reproducers of the sounds of speech and music. Any practicable device of this character for reproducing sound must necessarily have its limitations, for the faithful reproduction of even the simplest sounds is very difficult. As we have seen (p. 32), however, the ear is sufficiently accommodating to ignore fairly large defects in reproduction. Thus a 10% error in intensity, or possibly more than this, may pass unnoticed; the accuracy of *intensity* reproduction therefore need not be very great to conform with such a standard. *Frequency* reproduction, however, must be much more accurate to satisfy the ear, and it is indeed fortunate that the practical difficulties in this case are relatively small. Reproduction of sounds involves reception, and possibly transmission and amplification, as a preliminary. The process is well illustrated in the gramophone with either mechanical or electrical recording and reproduction. The recording system involves the direct mechanical action of sound-waves on a diaphragm, lever system, and engraving stylus, or alternatively on a system employing a microphone and a recorder operated electro-magnetically. In reproduction the process takes place in the reverse order, some form of horn, cone or diaphragm being utilised to couple the vibrations of the sound-box or electrical "pick up" with the external body of air. The present practice in design is to regard the complex mechanical system, *e.g.*, of a gramophone, as analogous to a corresponding electrical system. In this respect the analogy with electrical filter circuits, as stated by G. W. Stewart, has proved an extremely fruitful one. S. T. Williams and A. Whitaker have both applied this principle with considerable success in designing gramophone recorders and reproducers. By suitably choosing the inertia, stiffness and damping of the various elements of the sound-box and horn, a moderately good response-curve is obtained free from pronounced resonance within the speech-music range 150–4,000 p.p.sec. Electrical methods of recording and reproducing have recently yielded even better results. The desirable features in gramophones and loud-speakers are dealt with in a number of papers by various authorities in *Proc. Inst. Electrical Engineers*, Nov. 1923. The practical considerations are far too numerous to mention here but the essence of the problem of faithful reproduction lies in the avoidance of predominant resonances in the electrical and mechanical systems. This result may be achieved in some degree (a) by arranging that the natural frequencies of all elements of the system are far removed from any frequency it is desired to reproduce, (b) by the use of heavy damping, or (c) by making use of multiple resonance, *i.e.*, arranging the various resonance peaks to overlap in such a way as to give a fairly uniform response. (*See* Rothwell, *Nature*, Feb. 24, 1923, and Porter, *Phys. Soc.*, Feb. 1924.)

Mention has already been made of the recording of sounds on a film by means of light of variable intensity (Rankine, *loc. cit* p. 33). When a beam of light, after passing through such a film moving at the recording rate, falls on a sensitive cell (selenium, thalofide or photoelectric) the original sounds may be reproduced in a telephone or loud-speaker connected in circuit with the cell and a suitable amplifier. "Speaking films" have been produced successfully on this principle, the speech record being made on the edge of the film simultaneously with the cinema pictures. (*See* SELENIUM CELL.) Numerous other optical methods have been employed, with more or less success, to modulate a beam of light as a means of sound-reproduction, *e.g.*, use has been made of the Kerr electro-optical and the Faraday magneto-optical effects, and of the luminous electric discharge in rarefied gases.

Musical Instruments.—To deal adequately with the technical application of sound to the design and construction of musical instruments would require a very lengthy article in itself. Occasional references to such applications will be found above (section on Sources of Sound), but for detailed information the reader is referred to treatises such as *The Dictionary of Applied Physics* or Millar's *Science of Musical Sounds*.

The Acoustics of Buildings.—This subject is discussed in a separate article under that title.

Sound-Signalling.—In the section on sources of sound, reference has been made to various types of siren and the diaphone (p. 15) for producing powerful sounds in air, mainly for use in fog-signalling from light-houses and light-ships. Under the sea, large bells are used for a similar purpose. A more powerful under-water signalling device, due to Fessenden, employs a large diaphragm forced into resonant vibration under water. The apparatus consists essentially of a transformer, the secondary of which is free to move in a strong radial magnetic field. The primary is supplied with alternating current, and the resulting periodic motion of the secondary (a copper cylinder) is communicated to the submerged steel diaphragm which gives rise to sound waves in the water. The Fessenden oscillator, as it is called, is further mentioned on p. 35. The same device operates, conversely, as a receiver of sound-waves, these being converted into electrical oscillations by the vibration of the copper cylinder in the magnetic field, the induced currents in the primary coil being amplified and passed through telephones. Fessenden has used the apparatus to transmit signals through water to dis-

tances exceeding 30 miles and has even used it to transmit speech for a distance of half a mile. The oscillator has also been applied to detect icebergs and to take continuous depth soundings by echo methods (*see* below). In another form of oscillator, which is manufactured by the Signal Gesellschaft. Kiel, Hahneman has obtained powerful signals by means of a diaphragm excited in a different way. The diaphragm forms one member of a coupled system of two masses connected by a stiff spring (metal tubes). A powerful alternating current magnet causes periodic stretching of these tubes with corresponding vibrations of the diaphragm. A transmitter of this type weighing about 5 cwts. and having a diaphragm 18 inches diameter, gives a sound output of 300 to 400 watts, the mechanical efficiency being about 50% Reference to supersonic directional transmitters of the Langevin type, and to directional receivers, has already been made (*see* pp. 31 and 32 respectively).

Echo Depth Sounding.—Since the war considerable progress has been made in the development of new systems of sounding at sea. These new methods all employ, most appropriately, sound-waves as a means of measuring depths. The saving of time and labour is enormous and such methods are steadily replacing the old lead and wire systems which have survived so long. A sounding in 4,000 fathoms can be made in about 10 seconds by the new "echo" methods, whereas many hours labour are involved to obtain a somewhat uncertain value by the old "wire" system. An additional advantage lies also in the fact that observations of depth can be made whilst the ship is in motion, up to speeds of 15 or 20 knots The echo method involves the measurement of distance in terms of the time interval between the initiation of a sound impulse and the reception of an echo. This requires a knowledge of the velocity c of the sound waves in the medium, water or air, and depends on the fact that sound is reflected from the sea-bed in the same way that it is reflected in air from buildings and cliffs. The distance travelled by the wave in the time t is $2D$, the depth D is therefore equal to $c/2t$. Various systems have been devised in America, France, Germany, and Great Britain, differing in the manner of producing and receiving the sound impulse and in the measurement of the time interval. In the Behm system, a small detonator is fired under water thereby operating a microphone and relay and setting a graduated disc in motion; the arrival of the echo stops the disc which is engraved in "depths." The angle through which the disc has revolved is a measure of the time interval t and consequently of the depth D. The system developed by the British Admiralty depends on the indirect measurement of the time interval The transmitter consists essentially of a steel diaphragm which is struck a powerful blow by an electro-magnetic hammer, thereby emitting a heavily damped sound-wave of about 2,000 p.p.s. The receiver is an ordinary "button" carbon granule microphone mounted on a small diaphragm and enclosed in a watertight container. The transmitter and receiver are mounted in water-filled tanks fitted inside the ship's plates at points screened by the hull. A small motor drives two commutator switches at constant speed. One of these commutators actuates the hammer three times per second whilst the other short circuits a pair of brushes across the listening telephones except at one particular moment during which they can "listen." The position of these brushes may be displaced by hand relative to the corresponding brushes in the transmitter circuit, so that a short time interval, proportional to the angular displacement of the brushes, separates the initial sound impulse and the moment when the telephones listen. Nothing is heard therefore unless this moment coincides with the moment of arrival of the echo. The angular displacement of the brushes measures the time interval ($360^\circ \equiv \frac{1}{3}$ second). The dial attached to the rotatable telephone brushes is graduated in feet, or fathoms, and depths may be taken continuously whilst the ship is in motion. Two types of apparatus have been developed, (a) The shallow water set (described above), up to 150 fathoms, and (b) Oceanic depth apparatus, up to 4,000 fathoms or so. Both types are in regular service in numerous British and foreign commercial vessels and in the survey ships of the British Navy. Fessenden (U.S.A.) has devised a depth sounding system similar to the above, using his "oscillator" for the purpose of generating the short sound impulses. He claims in addition to depth sounding, to have used the apparatus to detect icebergs at distances up to $2\frac{1}{2}$ miles, a somewhat remarkable and surprising result, in view of the dimensions of icebergs, the wave-length of the sound (10 ft. approx.) employed, and the poor reflecting properties of ice under water. Boyle and Reid, using a Langevin directional quartz oscillator at supersonic frequencies could not detect an iceberg beyond 200 yards. The echo from ice was found to be very feeble compared with that from a rocky shore. The supersonic method has also been employed by Langevin and by Boyle in depth sounding; a good echo from the bed of the sea being easily distinguishable at considerable depths.

Sound-Ranging.—The location of hostile guns on land, and of submarine explosions at sea, constitutes one of the most important practical applications of sound during the war. Ordinary directional receiving devices such as those already considered are of little service when the sound consists of a sudden impulse or shock. The location of the explosion originating the impulse requires a special technique which is generally called sound-ranging We shall deal first of all with the war-method or *multiple-point sound-ranging* In this method three or more receivers are mounted at known positions on surveyed base lines The spherical explosion wave WF passes over, say, four receivers, 0, 1, 2, 3, in succession, the times of passage being recorded at instants $t_1\ t_2\ t_3$ respectively. The construction shown in fig. 17 indicates in a simple manner how the explosion E is located If we draw circles of radii $ct_1\ ct_2$ and ct_3 with centres at 1, 2, 3, respectively, c being the appropriate velocity of sound, then a circle WF which passes through the receiver 0 and is tangential to the three small circles will have the point of the explosion E at its centre

The accurate mathematical method of determining E from the values $t_1\ t_2$ and t_3 depends on the fact that this point lies at the intersection of hyperbolae having the various receivers 0, 1, 2, 3, as foci.

Army Sound-Ranging.—Six microphones were generally used, spaced along a base about 9,000 yards long and 4,000 yards behind the front line, a central recording station, to which the microphone leads were brought, being situated 5,000 or 6,000 yards from the front line. For hostile gun-ranging a special type of microphone, particularly sensitive to the low frequency disturbance of the sound of discharge of the gun, was devised This microphone, known as the *resonant hot-wire microphone*, invented by Tucker, has already been described (*see* p. 31) The hot-wire grid was mounted in the opening of a large Helmholtz resonator of about 16 litres capacity, the system responding only to very low frequency gun-sounds, whilst ignoring shell-wave (onde de choc), detonation of shell, and noises such as speech, traffic, or rifle fire The resonance set up by a gun-sound produced cooling of the grid with consequent variation of the electrical current flowing through it This current-change was photographically recorded at the central station by means of an Einthoven string galvanometer fitted with six strings, one for each microphone The resulting record, which was automatically developed and fixed, showed the six gun "signatures" on lines running parallel to the film. Across these lines, *i.e.*, at right angles to the film, were a series of time marks every hundredth and tenth of a second, providing a direct means of measuring the time intervals with an accuracy of 0·001 second, if the requirement of such was essentially needed. The record was started when a forward observer, or a "sentry" microphone, heard the gun, *i.e.*, a few

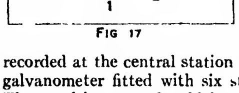

FIG 17

seconds before the sound-wave reached the first receiver on the base. The measured time intervals were corrected for temperature and wind, which have a considerable influence on the velocity of sound (*see* p. 5). Variation of these factors with height results in troublesome refraction corrections, and under certain conditions of wind gradient, sound-ranging became impossible. The sound-ranging method could, under certain conditions, be employed to locate both an enemy gun and the *answering* shell-burst, in which case the comparative records eliminate uncertainties arising from atmospheric conditions.

Navy Sound-Ranging.—The method employed at sea during the war was based on the same principles, but the receivers were essentially different. Under water, the sound of an explosion was received on a steel diaphragm on which was mounted a sensitive granular microphone. The diaphragm formed the cover of a watertight case mounted on a large tripod which rested on the sea bed. Four or more of such "tripod hydrophones" were laid in accurately surveyed positions on a 12 mile base line. They were connected by means of cables to a six-stringed Einthoven galvanometer in the recording station on shore, the subsequent procedure to obtain photographic records of an explosion being essentially the same as outlined above. Specimen records have been made of such explosions. During the war, explosions of mines, depth charges and torpedoes could be located with great accuracy at distances of 50 or 60 miles from the base line of hydrophones. Since the war the method has been applied to the accurate location of buoys and light-vessels, a small charge being fired under water in the vicinity of the point to be surveyed. For such purposes it was necessary to know the velocity of sound in sea water at different temperatures and salinities, with great accuracy (*see* p. 5). As an alternative to the Einthoven photographic recorder system of measuring time intervals, A. B. Wood and J. M. Ford (see *Jour. Sci. Instr.*, Mar. 1924) have devised a "Phonic Chronometer." This consists essentially of an electromagnetically operated stop-watch with three sets of dials for measuring three independent time intervals. The speed of the chronometer is governed by a tuning fork and phonic motor giving an accuracy of 1 in 10,000. Time intervals are indicated directly on the dials to 0·001 second. Special diaphragm shock receivers were designed for use with the chronometer, which was started and stopped as the explosion-wave passed the various receivers, the time intervals being read directly on the dials.

Radio-Acoustic Sound-Ranging.—This method which for obvious reasons could not be used in war time, was first proposed by Joly, and has recently been developed by A. B. Wood and H. E. Browne for the British Admiralty (*Proc. Phys. Soc.*, April 1923). It consists in the simultaneous emission of a "wireless" signal and an explosion impulse. The former travels with the velocity of light (186,000 miles/sec.) the latter with a velocity about 1 mile a second in water. If, therefore, one string of the Einthoven galvanometer on shore records the radio-signal whilst the others record the arrival of the explosion wave at the various hydrophones, we have a very simple and direct means of locating the explosion. The distance of the explosion from the hydrophones is given by ct_1 ct_2 ct_3, etc., where c is the velocity of the sound in the sea and t_1 t_2 t_3 are the time-intervals between the arrival of the wireless signal and the explosion-wave at the respective hydrophones. A 9 oz. charge of guncotton can be located in this way at 40 miles, whilst larger charges have been located up to 80 miles or more. At 80 miles the sound-wave through the sea arrives $1\frac{1}{2}$ *minutes* after the wireless signal which denotes the instant of firing the charge. The method permits of very great accuracy and has important applications in navigation and hydrographical survey. For navigational purposes great accuracy is sacrificed to speed, it being possible to give a ship in fog 40 miles away a position within a radius of half a mile in less than 10 minutes of receiving her request for a location. In hydrographical survey work the method has been used successfully to fix accurately the positions of buoys and light-vessels out of sight of land. The method is accurate in rough or foggy weather and at all seasons of the year. Various ingenious proposals have been made to safeguard ships in fog, by application of radio-acoustic methods (*see* Joly "Scientific Signalling and Safety at Sea," *Phil. Mag.* July 1918).

SOUND, THE, the easternmost of the straits giving entrance to the Baltic Sea from the Cattegat, between the Danish island of Zealand and Sweden (Danish *Oresund*). Its extreme length from the promontory of Kullen to that of Falsterbo is 70 m. Its narrowest point is between Helsingör in Denmark and Helsingborg in Sweden, which are 3 m. apart. Its extreme width, 30 m., is where Kjöge Bay indents the coast of Zealand. Three islands lie in it—Hven, belonging to Sweden, and Saltholm and Amager, belonging to Denmark. The strait between Amager and Saltholm is called Drogden, and is used by large vessels passing through the Sound. The extreme depth of the Sound is about 14 fathoms. Navigation is open in winter, though three instances are recorded of the Sound being frozen over: in 1306, 1830 and 1836.

SOUNDING. The determination of the depth of the sea has been practised from very early times for purposes of navigation, but it is only since the introduction of submarine telegraphy that extensive efforts have been made to obtain a complete knowledge of the contour of the ocean-bed (*see* Ocean).

For depths over 20 fathoms sounding machines are often employed and wire has entirely superseded hemp gear. Its smooth surface and minute section, reducing friction to a minimum, give a rate of descent of about 100 fathoms per minute. Reeling in may be accomplished at nearly the same rate. Such soundings can be obtained in any weather short of a fresh gale. A sounding of 1,000 fathoms may be obtained in 25 minutes and 3,000 fathoms in 75 minutes. But beyond that depth, great caution is required, the time occupied is increased, and reeling in must be done very deliberately. A sounding of 5,269 fathoms was obtained near the island of Guam by the U.S. cable-surveying ship "Nero." Soundings at such depths may occupy a period of time lasting as long as five or six hours.

Lucas Machine.—Among the sounding machines in general use the Lucas carries nearly 6,000 fathoms of 20-gauge wire, and is fitted with two brakes—one a screw brake for holding the reel when required, the other an automatic brake for stopping the reel when the weights strike the bottom. A guider for winding the wire uniformly is also attached. After leaving the reel the wire passes over a registering wheel, the dial of which indicates the length of wire run out. Smaller machines are used in boats.

Sounding Rods and Sinkers.—Under 1,000 fathoms a lead of 30 to 40 lb. weight can be recovered, and no detaching rod is necessary. For greater depths the "Baillie rod" is the best apparatus. It is a tube about 2 ft. long, having a rounded conical top, through which passes a movable steel rod. The lower part of the tube screws on and off, and contains a double flap valve to retain the bottom specimen. The sinkers, each 25 lb. in weight, conical in form, and pierced with a cylindrical hole through which the Baillie rod passes loosely, are slung by wire or cod line secured to a flat ring and passing over a projection on a movable rod to which the sounding wire is attached. The weight of the apparatus being taken by the sounding wire, the sinkers remain suspended; but on striking the bottom, the wire slackens, and the weight of the sinkers drags the movable rod down till the projection bears against the curved surface at the top of the rod. The wire sling is forced clear of the projection and the sinkers are slipped. In descending, the valves opening upwards, allow the

water to pass through freely; but on drawing up they are closed thus retaining the material with which the tube is filled. For depths under 2,000 fathoms two sinkers are sufficient. In deeper water a third cylindrical weight of 20 lb should be put between them. It is important to interpose a hemp line, some 20 fathoms long, between the end of the wire (into which a thimble is seized) and the lead or rod This prevents the wire from kinking on the lead striking the bottom.

Method of Sounding.—The machine is placed on a projecting platform on the forecastle As the wire runs out the brake must be gradually screwed up, so as to increase the power in proportion to the amount of wire out The regulating screw is marked for each 500 fathoms In fairly smooth water the brake will at once act when the weight strikes the bottom and the reel stops Under 3,000 fathoms one spring is sufficient, beyond that depth two springs are required

Handling the Ship.—Sounding from forward is preferable as it enables the ship to be handled with greater ease; in heavy weather when impossible to work on the forecastle, soundings may be obtained from a machine mounted over the stern The ship's head must be kept in a direction which is the resultant of the direction and force of the wind and current; and this is arrived at by altering the course while sounding, point by point, until the wire can be kept up and down by moving the engines slowly ahead as necessary

Observations of Temperature.—The temperature of the water is usually taken at intervals of 100 fathoms to a depth of 1,000 fathoms, and at closer intervals in the first 100 fathoms If a second wire machine is available, the observations may be made from aft whilst the sounding is being taken forward. A 30-lb. sinker is attached to the end of the wire, and the registering thermometers are secured to the wire by the metal clips at the back of the cases, at the required intervals To avoid heavy loss, no more than four thermometers should be on the wire at

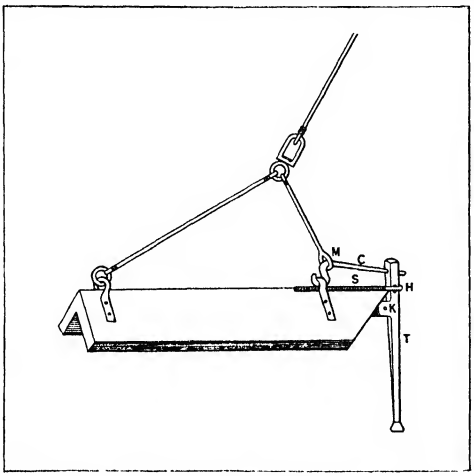

FIG 1.—SUBMARINE SENTRY

one time When sounding a thermometer is usually attached to the line a short distance above the lead

Submarine Sentry.—The primary object of the machine called the "submarine sentry" is to supply an automatic warning of shallow water; it has been instrumental in discovering many unsuspected banks in imperfectly surveyed waters. By means of a single stout wire the sinker, an inverted kite, called the "sentry," can be towed steadily for any length of time, at any required vertical depth to 40 fathoms; should it strike the bottom, it will free itself and rise to the surface, simultaneously sounding an alarm gong The vertical depth at which the sentry sets itself when a given length of wire is paid out is not changed by any variation of speed between five and 13 knots

The kite in its position when being towed is indicated in fig 1 The point of the catch C, passing through a thimble M in the short leg of the sling, is slipped into the hole at the top of trigger T, which is hinged at K and kept in its place by the spring S attached to the hook H On the trigger striking the bottom the catch is released, the short leg of the sling slips off, and the sentry, which then rises to the surface, is left towing by the long leg. The winch is fitted with two handles for heaving in the wire, one gives great power and slow speed, and the other, acting on the drum spindle direct, winds in quickly The wire supplied with the machine has a steady breaking strain of about 1,000 lb

For ship as opposed to boat work, in depths up to 50 fathoms the best known British systems are the "Douglas-Schafer" and "Somerville", these appliances are fitted in all British surveying vessels, and enable accurate and rapid soundings to be obtained when steaming at the rate of about four knots Both methods use a wire traveller carrying a lead between the stern of the vessel and a spar projecting from the bows and permit the lead being disengaged at its greatest distance forward, thus enabling a vertical sounding to be obtained as it passes the stern

Echo Sounding.—This new method depends upon the principle that any sound originating at or near the surface travels through the water at a known speed, and after striking any large object or the bottom of the sea is reflected back to the surface, the time between the emission of the sound and its reception back again being a matter for accurate measurement

The time necessary for obtaining a sounding is almost infinitesimal, the sounding in extreme depths taking little more time than one in the shallowest water The speed of the vessel is maintained throughout the soundings, the soundings themselves may be accurately taken at extremely short intervals and bad weather does not affect the work *See* also CHART and SOUND

SOUND MOTION PICTURES. Since the first days of motion pictures efforts have been made to provide the addition of an appropriate sound accompaniment or speech, accurately synchronized with the motion picture, which would add realism and artistic value to the performance The requirements of such a system are that the picture shall be as clear as heretofore, that the sound produced shall be appropriate and reasonably natural in quality and that the synchronism, or exact time relation, between the pictures and the sound shall be maintained, preferably by automatic means (*See* MOTION PICTURE PROJECTION) The reproduction of sound may be accomplished either from a phonograph record or from a sound record on the motion picture film itself that may be made in several ways, *e g*, it may be a long narrow band of variable density of developed silver deposit, the density variations corresponding to the wave outlines of the sound to be reproduced, or it may be in the form of a long narrow band, the width of which at any point varies as the wave form of the sound to be reproduced. It has also been suggested that the sound record on the film might be a mechanical indentation or wavy line impressed into the celluloid or the emulsion, in which groove a needle will rest as in a phonograph (*q v*)

The initial stages in recording on a film are similar to the first stages in electrical phonograph recording or in radio broadcast transmission. The performers appear before a microphone of high quality, the output of which is amplified by a vacuum tube amplifying system The output of the amplifier is used to control the recording device In some cases the intensity of a light source, *e g.*, a *neon*, or other gas-filled glow-tube, is systematically controlled, and this variable light is caused to shine on a narrow slit, or its optical equivalent, placed over the rapidly moving negative film In other cases the light from a constant source passes through a light valve or an aperture of variable width or a Kerr cell or similar device controlled by the amplifier output, and then falls on the stationary narrow slit placed over the moving negative film In each of the two preceding

methods a variable density record is produced. In another method of recording, a sharply limited beam of light from a constant source is reflected from an oscillograph mirror and focused upon a narrow slit or its optical equivalent, placed over the moving film. In this case a variable width record is produced.

The process of reproducing variable density, or variable width film sound records, consists in throwing on the continuously moving film a narrow line of light which optically takes the place of the phonograph needle. The light line, which is perpendicular to the direction of motion of the film and perpendicular to the sound track, on passing through the film is caught by a photoelectric cell, the varying output of which is suitably amplified electrically by vacuum tubes and used to actuate the loud speakers. The applications of sound motion pictures even at present are diverse. Films have been orchestrated, *i.e.,* provided with a suitable orchestral accompaniment permanently available to any theatre having the necessary reproducing equipment. News reel features have had embodied in them the synchronized sound of speeches, street noises, aeroplane motors in action, and the like. The reproduction of plays with the speech of the actors recorded as well as their appearance is now being developed, so giving the illusion of an actual occurrence or of a theatre performance.

See MOTION PICTURE: *Technology.* (A. N. G.)

SOUP, a liquid food consisting usually of stock (water in which meat or vegetables have been boiled) with or without other ingredients. Soups are also made without stock. As clear soups are largely water, they have little food value in themselves, but they act as appetizers. Cream soups, vegetable purées and chowders are higher in food value, and may be used as main dishes.

Stock.—In boiling meat for soup the meat is put into cold water in order to extract as much of the "goodness" as possible during the five or six hours of slow cooking, and it is usually cut small. The meat with which a good stock is made becomes a mass of fibrous, almost tasteless matter, which can be used only in some made dish to which seasonings are added. In some countries the meat is kept in one piece, so that it may be more usable as a main dish, but the stock in that case loses in richness.

Meat stocks are of two types, white and brown. For the first, the bones and meat of veal, chicken and turkey are used, often in combination. For brown stock the foundation is of beef and beef bones. one being a marrow bone tied in cheesecloth to prevent the escape of all the marrow. The usual combination stock is made of beef and veal. For white fish stock the heads and tails of fish are used, with no vegetables that will darken the mixture. Brown fish stock (court bouillon) is made with sliced fish, and vegetables that will make the liquid brown. The term vegetable stock is applied to the water in which vegetables have been boiled.

Brown stock is the traditional French *pot-au-feu.* To make, put a piece of beef, beef bones and if desired bones, legs and neck of a fowl into salted cold water. Bring slowly to boiling point. All scum must be removed from any stock the instant it appears. Reduce the liquid to the simmering point and add the vegetables—two onions stuck with a clove, two or three carrots, one turnip, one leek, one tomato, celery, pepper, salt and bayleaf. Simmer from five to six hours. For a clear soup the vegetables should cook no longer than two hours, and should be tied in bunches before adding. All stock is strained through cheesecloth or a sieve as soon as it is done. This is the clear soup or consommé with which many other soups can be made. If the stock needs clarifying, this is done by cooking with egg white and egg shells. A simpler way of making brown stock is to place the bones, two-thirds of the meat and the water in the stockpot to soak for one hour. The rest of the meat and one-third of the vegetables may be browned in a little fat. These are added to the pot, and the mixture simmered from three to five hours, the rest of the vegetables being added from one to two hours before the end of the cooking. For white stock the vegetables are onion and celery, with other white vegetables if desired, and the cooking time is an hour less than for brown stock. Fish stocks cook in one hour or a little more. Any stock may be used as the basis of other soups, the proper ingredients for the flavour wished being added.

Cream Soups.—These may have white stock, milk, cream or white sauce as the foundation. The last three are valuable ways of adding milk to the diet. A milk cream soup has 2½ cups milk to ½ cup strained cooked vegetable. A cream soup with white sauce adds ½ cup cooked strained vegetable or shellfish (bisque) to 3 cups thin white sauce. A cream soup with white stock adds 1½ cups strained cooked vegetable to 2 cups of the stock. Any of these proportions may be varied to suit individual taste.

Vegetable Soups.—These may have a stock foundation, may be cream soup, or may be made of vegetables, water and seasonings. Vegetable stock makes an excellent basis for a vegetable soup. A thick soup is called a purée, and those made of the legumes (usually dried) are of high food value. The combinations of vegetables possible are endless. Onion is an invariable ingredient, though this may be in the form of leeks or chives. The vegetables should be cut up and tossed for two minutes in butter. This preliminary frying adds richness and flavour. Boiling water is added and the liquid allowed to simmer for at least two hours.

Chowders.—These are hearty soups that might in some cases be called stews. Fish chowders are many, of which the most famous is the Bouillabaisse from Marseilles. Clam chowder is a favourite in the United States. Vegetable chowders are made of combinations of vegetables, sometimes with a single vegetable giving the predominating flavour, as in parsnip chowder or green corn (maize) chowder. Gumbos are thick soups made with okra.

The soups associated with certain nations are hearty ones, sufficient with bread and perhaps cheese to serve as a main dish. France has the *pot-au-feu* and the *petite marmite* (adding chicken to the *pot-au-feu*), Italy *minestrone*, Russia *borch*, Holland *erwtensoep*, Spain *puchero*, South-western France *garbure.*

SOUR-SOP, called also guanabana (botanical name *Anona muricata;* family Anonaceae), a small evergreen tree, about 20 ft. high, native to tropical America. It bears a large, dark-green bluntly conical or heart-shaped fruit, 6 to 8 in. long and 1 to 5 lb. in weight, covered with short fleshy spines. The white, juicy, slightly acid, aromatic pulp has a flavour of mango and pineapple, and makes excellent jelly and preserves. The sour-sop is cultivated in the West Indies, tropical South America, Mexico, India, Cochin China, parts of Polynesia and the west coast of Africa. With some frost protection, it can be grown along the Florida coast as far north as Palm Beach. It is propagated by growing seedlings and by shield-budding. (*See* CHERIMOYA; CUSTARD APPLE; SWEET-SOP.)

SOUSA, JOHN PHILIP (1854–), American composer and bandmaster, was born at Washington (D.C.) on Nov. 6, 1854. His grandparents were Portuguese refugees. He was a pupil of John Esputa and G. F. Benkert for harmony and composition, beginning his musical education at six. At 19 he conducted for Milton Nobles; played in Offenbach's orchestra, Centennial Exhibition, Philadelphia, in 1876; and conducted *H.M.S. Pinafore* before Gilbert and Sullivan went to America, in 1879, for the New York production. In 1880, he became bandmaster of the U.S. Marine Corps band, which acquired a high reputation under his control. The title of the "march king" was bestowed upon him by an English brass band journal for his many marches. In 1892 he organized Sousa's Band, which won great renown. It visited Europe (1900, 1901 and 1903) and toured the world (1910–12). The golden jubilee of this veteran bandmaster and composer was celebrated in 1927. Belgian, English and French decorations were awarded him. His compositions include the comic operas, *The Smugglers, Désirée, Queen of Hearts, El Capitán, The Bride Elect, The Charlatan, Chris and the Wonderful Lamp, The Free Lance, The Glass Blowers* and *The American Maid;* many songs; 15 suites; more than 100 marches, of which the most popular were *The Washington Post, High School Cadets, Liberty Bell, Semper Fidelis* and *The Stars and Stripes Forever; The Chariot Race* (Ben Hur), a symphonic poem; and *The Last Crusade*, a short cantata for orchestra, organ and choir. He wrote *The Fifth String, Pipetown Sandy, Through the Year with Sousa, The Transit of Venus* and an autobiography.

SOUSA, LUIZ DE [MANOEL DE SOUSA COUTINHO] (1555–1632), Portuguese historian, was born at Santarem. After an extremely adventurous life he entered the Dominican monastery at

Bemfica in 1613, and took the name by which he is known as a writer, Frei Luiz de Sousa. In 1616, on the death of Frei Luiz Cacegas, another notable Dominican who had collected materials for a history of the order and for a life of the famous archbishop of Braga, D Frei Bartholomew of the Martyrs, the task of writing these books was confided to Frei Luiz. The *Life of the Archbishop* appeared in 1619, and the first part of the *Chronicle of St. Dominic* in 1623, while the second and third parts appeared posthumously in 1662 and 1678, in addition he wrote, by order of the government, the *Annals of D John III*, which were published by Herculano in 1846 After a life of about nineteen years spent in religion, he died in 1632, leaving behind him a memory of strict observance and personal holiness He was of noble family

There are many editions of the *Life of the Archbishop*, and it appeared in French (Paris, 1663, 1679 and 1825), in Italian (Rome, 1727-28), in Spanish (Madrid, 1645 and 1727) and in English (London, 1890) The *Historia de S Domingos* may be read in a modern edition (6 vols, Lisbon, 1866)

AUTHORITIES —*Obras de D Francisco Alexandre Lobo*, ii. 61-171; Innocencio da Silva, *Diccionario bibliographico portuguez*, v. 327, xvi. 72; Dr. Sousa Viterbo, *Manoel de Sousa Coutinho* (Lisbon, 1902).

SOUSLIK, terrestrial *Sciuridae* of medium size, with short flattened tails and cheek pouches, representing the genus *Citellus;* distributed widely over the Northern Hemisphere from Hungary eastward through Asia and North America to the United States. Formerly the Souslik inhabited Great Britain

SOUSSE, a harbour town of Tunisia Pop about 21,000. It occupies the site of the ancient Hadrumetum, an important Phoenician city which served Hannibal as his base of operations at the end of the Second Punic War Trajan made it a colony: the epithet *frugifera* (fruitful) which was given to it, alludes to the fertility of the surrounding country. At the end of the 3rd century A D it became the capital of the new province of Byzacena, and later it received the name of Justinianopolis. Fine mosaics are preserved and there are remains of the ancient harbour works and large Christian catacombs The native town, surrounded by mediaeval walls, has a citadel (Kasba); the "souks" (covered streets with shops) are interesting Phosphates are exported and there are oil mills.

SOUTH, ROBERT (1634-1716), English divine, born at Hackney, Middlesex, Sept 1634, educated at Westminster school and Christ Church, Oxford Before taking orders in 1658 he preached as a Calvinist against Socinianism and Arminianism, but after the Restoration his views changed On Aug. 10, 1660, he was chosen public orator to the university; in 1661 he became domestic chaplain to Lord Clarendon, in March 1663 prebendary of Westminster, and in 1667 chaplain to the duke of York A zealous advocate of the doctrine of passive obedience, he strongly opposed the Toleration Act In 1667 he was appointed chaplain to Lawrence Hyde (afterwards earl of Rochester), ambassador-extraordinary to the king of Poland In 1678 he was presented to the rectory of Islip, Oxfordshire. In 1693 South published *Animadversions on Dr. Sherlock's Book, entitled a Vindication of the Holy and Ever Blessed Trinity,* bitterly attacking the views of Wm. Sherlock To Sherlock's answer, *A Defence* (1694), he replied with *Tritheism charged upon Dr Sherlock's New Notion of the Trinity, and the Charge Made Good.* The controversy was finally stopped by the king. In 1710 South became a partisan of Sacheverell. In 1713 he declined the see of Rochester and the deanery of Westminster. He died on July 8, 1716, and was buried in Westminster Abbey.

His *Sermons* (6 vols., 1692) were reprinted many times; there is a modern edition in Bohn's classics (2 vols, 1845), and a complete edition of his *Works* (5 vols, 1842). *See* also W. C. Lake, *Classic Preachers of the English Church* (1st series, 1877).

SOUTH, THE, a large area of the United States which presents certain distinctive characteristics.

The south-eastern quarter of the country includes 6 of the original 13 States, Delaware, Maryland, Virginia, North Carolina, South Carolina and Georgia, and 11 States added since the formation of the Union, viz., Kentucky (1792), Tennessee (1796), Louisiana (1812), Mississippi (1817), Alabama (1819), Missouri (1821), Arkansas (1836), Florida (1845), Texas (1845), West Virginia (1863) and Oklahoma (1907). Delaware, Maryland, West Virginia, Kentucky and Missouri which lie next to the Northern States are often referred to as "border" States, and because of their location the differences which distinguish the South from the North are in them less defined. During the Civil War, for instance, the border States, although slave-holding States, did not secede from the Union Delaware, since the Civil War, generally considers itself a Northern State, while Missouri has become definitely mid-western Texas and Oklahoma also share many of the Western characteristics Because they were settled by Southerners, however and were slave States they are considered historically as part of the South

Historical Development.—At the time of the first census in 1790 the populations of the two major divisions of the country then existing, the North and the South, were practically equal (1,967,197 and 1,962,428 respectively), and their influence in the control of the Federal Government was about evenly divided In the decade 1790 to 1800 the population increase in the North (36.5%) was slightly more than in the South (33 7%) In each succeeding decade up to 1860 the growth of the North was greater, and that of the South less, than its increment in the initial decade until, in 1860, the numbers were 20.309.960 and 11,133,361 respectively. Because of its proportional loss in population, the South was forced to wage an increasingly desperate struggle to retain its former influence in the Federal Government, and thus to protect its peculiar interests, the chief of which was the institution of slavery Slavery, which had in colonial times become rooted in Virginia and Maryland in connection with the raising of tobacco and along the Carolina coast in connection with the raising of cotton, spread rapidly after the introduction of the cotton gin about 1800 The gin made profitable the raising of a kind of cotton containing many seeds which grew in the upland Piedmont regions and in the interior, where the cotton with fewer seeds would not grow. Under this stimulus plantations grew rapidly in the fresher lands of the newer Gulf States to the west, while the tobacco industry also found fresh ground in Kentucky and Tennessee Slavery also assisted agriculture

Despite the difference in population the number of Slave States and free States remained equal until the admission of California as a free State in 1850, and because of this the South kept its influence in the Senate unshaken until that date The decreasing power was evident long before, however, and the South was led to the adoption and development of the doctrine of State sovereignty to protect its interests This doctrine was resorted to in 1832 to defend itself against a tariff imposed by Northern interests which the South believed to bear heavily upon itself, but the matter was smoothed over for the time being by a compromise tariff Compromises upon the slavery question were also made in 1820 and in 1850, but neither was permanent, and by the very nature of the institution it seemed a permanent compromise was impossible Finally, in defence of slavery, the Southern States carried their doctrine of State sovereignty to its ultimate conclusion and seceded from the Union, forming a union of their own, known as the Confederate States of America. After four years of bitter Civil War the South was left beaten and exhausted

There followed a long period of both economic and spiritual depression in the South which was felt not only by the generation of adults then living, but by the next generation as well. The recovery might have been more rapid had President Lincoln's wise and humane plan of reconstruction been carried through, but Lincoln's assassination and his successor's unfortunate quarrel with the dominant Republican Congress proved a disaster for the South. By the Reconstruction Act of 1867 the seceded States, except Tennessee, were divided into five military districts, each under the command of a Northern army general. The defeated States were not to be readmitted into the Union until they had met a programme of requirements, which was not done by any of them until 1869 and 1870. In the meantime control of the governments in most of the States had been in the hands of ignorant negroes or newcomers from the North, generally stigmatized as "carpet baggers," and it was not until a decade after the close of the war that the Southern whites again gained control Only then was economic

habilitation able to go forward on a firm basis. It was a generation before education and allied cultural developments gathered momentum enough to again move forward.

Because they felt that the Republican Party had forced the Civil War and the reconstruction programme upon them the secession States after their readmission were solidly Democratic in their political sympathies until 1928. The border States, Delaware, Maryland, West Virginia and Kentucky, however, fell away from Democratic allegiance with the McKinley election of 1896, and Missouri followed in 1904. (X.)

INDUSTRIAL DEVELOPMENTS

The industrial history of the South falls into four periods: (1) healthy beginnings, manufactures mixed with agriculture, to the end of the War of 1812, when British manufactures coming into America put an end to industries already on the wane; (2) lapse of manufacturing to the end of reconstruction, or, say, 1880, due to absorption in cultivation of staple crops with slave labour; (3) industrial revival with recovery from war, passing of political vexations and re-emergence of free white labour, reaching to the outbreak of the World War; (4) expansion and diversification of industry, marked by southward migration of capital.

The South in 1925 had about 33,500,000 population, or approximately 28% of that of the country, and the total value of its manufactured products was $7,755,195,000, or approximately 12%. Per caput production of manufactures in the South (measured by value of product) was in 1925 about $231, or less than half of that for the United States as a whole. However, the percentage value of Southern manufactured products has constantly mounted (with the exception of a slight recession between 1920 and 1923) from 6·2% in 1880 to 12·37% in 1925.

Between 1910 and 1920 the proportion of all Southerners gainfully employed in manufacturing and mechanical industries rose from 14·7% to 18·2%. In the United States as a whole, the figures for the same years were 27·8 and 30·8%. Thus the South has rather more than half as many of its wage-earners in industry as the whole country. Of the aggregate value of industrial products in the South in 1925, cotton manufacture was responsible for 10·5%. General manufactures, however, have made greater progress than cotton goods in the past few years. Hydro-electric power ushers in a period of more wide-spread and varied industry. The South in 1925 had 5,696,809 primary horse-power, which was 15·93% of that for the country. Of this total, electric motors driven by purchased current had 2,212,805 h.p., being 13·94% of the purchased electric current of the country. That is, about 31% of the total horse-power in the South is rented current, as opposed to about 50% in the entire country—a good showing for a district in which manufacturing is comparatively recent. The power companies, steam and hydro, which are springing up throughout the South, are duplicating campaigns of the railroads with the purpose of drawing new industries to the region. Southern society is beginning to coagulate, as it were; in 1900 about 14% of the population of the section was urban; in 1929 more than 25% live in cities.

Textiles.—Cotton manufacturing is the South's predominant industry. The cotton mills convert the South's characteristic raw material, and employ roughly one-third of all industrial workers. This is one of the few manufactures, capable of being conducted elsewhere, in which the South has assumed leading place. In 1926 the South's 814 cotton mills contained 48% of the spindles in the United States, but of more significance is the fact that the South's 17,612,000 active spindles were nearly 57% of the country's total. The South had almost half of America's looms. The cotton-growing States in 1925 turned out cotton goods worth $929,107,255 or 53% of the country's total, using, for the year ending July 31, 1926, 4,796,000 bales of cotton, or two-thirds of the total American consumption of American cotton. North Carolina, both in number of wage-earners (84,183 in 1925) and value of products ($316,324,008) was the leading Southern State in cotton manufacture, with South Carolina, Georgia and Alabama next in order. The cotton mills in the South prior to 1880 were generally small, scattered, inefficient and made a coarse product, mostly yarns. At that time the South had recovered in a measure from the Civil War, sectional bitterness was allayed, and the abolition of slavery brought the "poor whites" to public notice as a labour asset. Manufacture of the everywhere-present cotton seemed the obvious recourse. Towns vied with each other in a boom of mill building, 78 new plants appearing by 1890 and 162 more by 1900. In these two decades active spindles in the South increased from 561,000 to 4,368,000. Local communities sought capital with which to put up the buildings, and leaders in the ventures went North to secure working funds and equipment. Ordinarily commission firms taking stock were given the selling account of the mill, and machinery makers, who were glad of orders after the long depression, accepted shares in payment. Where water-power was not available, steam was eagerly turned to. These mills were extraordinarily successful, regularly making profits up to 50% of the invested capital. Cotton was bought locally at a saving, and was in the best condition, coming frequently directly from the gin without baling. Wages were much less than in the North, hours were longer, the proportion of women workers was large and child labour was universal. There was no complaint against these conditions. What the poor whites wanted was security, and they found this in the mill villages. Cotton mills employ whites. They come from all regions; at first, principally from Piedmont and the mountains. A very few negroes are employed separately.

Costs of cotton manufacturing in the South are lower than in the North. Probably the most careful estimate is that of Charles T. Main and Frank M. Gunby, of the American Society of Mechanical Engineers, published in Oct. 1926. Their conclusion was that a Southern mill running 55 hours a week had a cost 16·8% less than a Massachusetts mill operating 48 hours a week, taking no account of the expenses connected with maintenance of a mill village. This is equivalent to a saving to the Southern manufacturer of $6.73 per spindle per year, of which saving lower labour costs were responsible for $4.53. If the cost of mill villages North and South is included, there is still a differential in favour of the South of 14%, or $5.60 per spindle per year.

In 1925 the average earnings of the cotton mill operative in the ten leading Southern States were $632.95, or a weekly wage of $12.17. If we take only the four leading Southern States—North and South Carolina, Georgia and Alabama—the average wage for 1925 becomes less, $625.53 for the year, or $12.02 per week. The average annual earnings in the four leading New England States—Massachusetts, Connecticut, Rhode Island and New Hampshire—were $969.45, or 55% higher than the same item for the four leading Southern States.

There is a high labour turnover in Southern cotton mills, estimates two decades ago running as high as 30% of the proportion of "floaters" in the working population, though it is by some manufacturers believed now to be as low as 10%. Companies seek to anchor their help through welfare provisions, but the family's belongings do not make more than a wagon load, and moving on to the next mill town is one of the few ways in which the workers can declare their independence. The value added by manufacture is greater in the Northern mills than in the Southern. Wages formed a higher percentage of the value added by manufacture in Northern States than in Southern, the greatest spread being between 76% for Maine and 42% for Virginia and Alabama (figures for 1923). All of the Southern States were below the national average of wages, and all of the Northern were equal to or above it.

All of the principal Southern States have (1929) laws forbidding the work of children below the age of 14 in cotton mills, but above this age they may work as long as adults, with the exception of North Carolina, where a child of 14 without a fourth-grade schooling may not work more than eight hours. Between 1870 and 1900, while other sections of the country decreased their percentages of child workers by a half to two-thirds, in the South the percentage of children to all wage-earners increased from 23 to 25. Northern and Western cotton mills now have about the same proportion of children employed as Southern mills, though the hours of the latter are longer.

The low wages of Southern operatives have been the principal cause of the working of all available members of the family

group. Income to the family is further supplemented by the free or very cheap services which employers render The typical Southern mill is surrounded by a village owned and administered by the company. It has been estimated that 25% of the capital of the Southern cotton manufacturer is invested in the village—in operatives' houses, stores, streets, schools and welfare and recreational facilities The average Southern operative pays for his house only 25 cents per room per week, in exceptional cases the rent is 75 cents per room per week for excellent cottages, and sometimes the employer furnishes houses entirely free of rent

Beginning about 1923, there has been a conspicuous drift of the American cotton manufacturing industry to the Southern States An unofficial estimate is that since then more than $100,000,000 has been invested in the building of new mills in the South or the purchase of existing Southern plants, mostly by New England interests. Still, the capital in Southern cotton mills is probably more than 80% owned in the South Between 1924 and 1925, the South passed New England in the number of active spindles, and this lead has greatly increased since From July 31, 1922 to July 31, 1926 the South gained 1,668,000 active spindles, while New England showed a loss of 2,413,000 and the rest of the country a loss of 213,000 Of spindles in place, in the same period, the South gained 1,800,000, while New England lost 910,000, and other States lost 249,000; to take the extremes, North Carolina gained 782,000 spindles while Massachusetts lost 506,000 Every one of the six Southern States listed by the census in this connection gained spindleage, while every one of the New England and middle States lost Comparing the average amount of cotton consumed, 1921–25 and 1925–26, the South gained 689,000 bales, while New England lost 104,000 bales and the rest of the country gained 2,000 bales Between 1923 and 1926 the South gained 7,919,000,000 spindle hours, as against a gain of 1,439,000,000 for New England and 223,000,000 for the rest of the country Between 1923 and 1925, the value of all cotton manufactures of the United States decreased (those of the South only a third as much as those of New England), but between 1921 and 1925 the products of Southern mills increased in value 65 4%, while those of New England increased 5 7% and those of the entire country 34 1%

Southern textiles have been of a coarse nature, and this is still true in the main, but a steady progress in quality and variety of output has characterized the years since 1915 The South manufactures cotton goods falling in all of the 28 more general classifications of the 1925 census, and it is notable that in all but three instances—bunting and bandage cloths, table damask and tyre fabrics other than duck—the South either led New England in the per cent of increase, or suffered a less decrease than New England Of 31 more particular classes of goods, the South contributes to 21 and is represented by individual plants in others

The manufacture of knit goods, chiefly from unmercerized cotton yarns, but also from silk and rayon, has had a striking growth in the South, adding an important branch of the textile industry The total value of products for 1925 was $123,352,791, a gain of $14,613,442 over 1923 In 1923 Tennessee was the leading Southern State in knit goods, and in 1925 this industry still ranked first in the State in number of wage-earners (14,986) and value of product ($44,006,467), but by the latter year North Carolina had passed it in value of product—111 plants turning out goods, chiefly hosiery, worth $44,300,819 Half of the production of Tennessee is hosiery, and one-fourth knit underwear While there are 241 knit goods plants in eight Southern States, the chief centres are Durham and Winston-Salem, N C., and Knoxville and Chattanooga, Tenn Georgia ranks third in the industry in the South, with products worth $17,020,011 Negro operatives are used in part in this industry, particularly in North Carolina, on coarser grades of output. Wages in the knit goods industry, as in cotton manufacturing proper, are conspicuously lower in the South Southern knitting mills are turning to the national market with their finer and more specialized products. While the industry in the South has grown remarkably, it does not as yet threaten the older centres such as New York and Pennsylvania

Except for scattered plants, the South until recently had no means of dyeing, bleaching and finishing its textiles within the section, but was wholly tributary to New England in this important department Finishing plants were being established rapidly in the South, there being 23 in 1923 and well over 40 in 1928, North Carolina having the largest number The new rayon industry is adding another branch to Southern textiles. In the two years ending in 1928 more than $25,000,000 has been invested in rayon manufacture in the South, mainly in central and eastern Tennessee, and Virginia and West Virginia

Tobacco.—Tobacco manufacture, in one form and another, is as old as the South Before the Civil War a crude manufacture was carried on in the homes of the farmers, and factories were scattered through the rural districts and small towns, as well as in the cities The Civil War brought the first movement toward concentration by destroying many of the weaker factories While it reduced the number in the cities (in Richmond from 50 to 38 in Lynchburg from 35 to 16, for example) it also worked a compensation by popularizing smoking in addition to the older habit of chewing The soldiers used tobacco universally, and the Northern armies acquired a liking for the Southern tobacco

Early in the '70s, though checked by the panic of 1873, production mounted The heavy taxes on manufactured tobacco which affected Southern manufacturers immediately the war was over, favoured the factory owner who had a little more capital than his competitors and was a little more cunning in evasion Thus concentration in the industry was further encouraged Then came the cigarette machines Cigarettes were not much smoked in the United States until about 1880, and then were made by hand The cigarette machines led on to formation by a young Southerner, James B Duke, of the American Tobacco Company, the "Tobacco Trust," in 1890 Duke, after a promising success with his father and brother at Durham, during which time he invented the sliding cardboard cigarette package, had established a branch cigarette factory in New York city For six years he set the pace in the "tobacco war" between rival large manufacturers, in which millions were poured out for advertising competing brands Finally, five firms were forced into a combination The combination, of which Duke was president, paid high dividends and branched out into the manufacture of plug tobacco and all-tobacco cigarettes The older plug tobacco factories in the South had employed a large proportion of negro men with negro women working as stemmers The cigarette factories, where the work was light, though confining, tedious and unhealthy, brought a shift to white operatives The tobacco factories exploited the poor whites of the South especially women and children In 1905 in Virginia, North Carolina and Kentucky, the average annual wage of men was $272, of women $183 and of children $119 In the North wages ranged at least 25% higher. Though the proportion of children in the industry the country over fell from 21 to 9% between 1880 and 1905, North Carolina, which remained the worst offender, had almost 20% children in the latter year

The tobacco industry in the South is given more largely to machine production than that of the country generally The manufacture of cigars in Florida, mostly by hand, is the outstanding exception, this State in 1926 paying a larger internal revenue tax on cigars ($4,089,643) than any States except Pennsylvania and New York This industry is far more localized than textiles, the chief Southern States being North Carolina, Virginia and Kentucky, in order Winston-Salem is the largest tobacco manufacturing centre, and Reidsville, Durham and Statesville, N C , are the other chief points in that State The extent to which the North Carolina industry is mechanized, is indicated in the fact that while it employs a little over one-third more workers than Florida, the value of its products is eight times as great North Carolina in 1925 produced almost 35 thousand million more cigarettes than New York, its closest rival in this branch While machine tobacco workers in the South are still poorly paid, it is probable that they have more to spend, on the whole, than textile operatives

Iron.—The national importance of this industry in the South dates from the founding of Birmingham, Ala , in 1870 Birmingham has coal, iron ore and fluxes almost within a stone's throw of each other The main coal fields are the Warrior, to the west of

Birmingham valley, producing about 85% of the coal output of the State; the Cahaba on the east, producing 12%, and more to the east the Coosa field, producing about 4%. Between the Warrior and Cahaba coal fields, on the ridges just above the geologic horizon, lie the hematite or red ore, and limonite or brown ore; for fluxing, the bed of the valley contains great areas of limestone and dolomite. The red ore is the main reliance of the district, being mined chiefly from the Red mountain outcrop between Birmingham and Bessemer. Grey hematite of Talladega county may be important in the future. The red hematite is of two varieties, popularly termed soft and hard. The soft ore is that reaching down from a few feet to 400 ft. below the outcrop, in which the action of water has leached out the lime carbonate, thus increasing proportionately the content of iron oxide and other constituents. Limited in extent, easily mined and rich in iron, the soft ores were worked out first, and are no longer important. The hard ore of the Birmingham district ranges from 32 to 45% metallic iron, with varying percentages of lime, silica, alumina, magnesia, sulphur and phosphorus. The phosphorus content runs from 0·25 to 1·5%, thus rendering the ore unfit for the Bessemer process of steel-making. The Birmingham district must now reach its hard ore by vertical shafts 1,000 to 2,000 ft. deep, or by slopes three or four times the length, but there is the compensation that these deeper-lying ores may contain enough lime to be self-fluxing.

Alabama has coal reserves of about 66 thousand million short tons. Half a million tons were mined in 1880, the industry really getting under way only after the opening of the Birmingham iron district. Iron making at Birmingham, despite the presence of coal, began with charcoal as fuel. The Tennessee industry was wholly of this nature. Coke was first made in Alabama in 1854, and the next year, near Ragland, was applied to foundry use, but the iron and coke industries in this State did not receive their impetus until in 1876 coke of the native coal, made in bee-hive ovens at the Oxmoor furnace in Jefferson county, was used to produce pig iron. From 1,262 tons of pig iron made with coke in this year, the production has grown to upwards of three million tons in 1925. The first steel was poured in Alabama in 1888, but up to 1897 the total tonnage of basic open-hearth steel made at North Birmingham did not exceed 3.500 tons. Prior to 1890 Birmingham iron masters exported much of their product. This did well enough until the great Mesabi range in the Lake Superior region was opened. Bessemer pig iron at Pittsburgh fell off sharply in price, due to the cheap new ore—from $23.60 in Jan. 1890, to $13.60 in Jan. 1893. In the years of lowest prices, 1897–98, Mesabi non-Bessemer ore, after paying all costs of mining and shipping, was selling at Lake Erie ports at $1.70 to $1.80 per ton, and Bessemer ore at $2.10 to $2.15. This revolution in the industry was almost disastrous to the Birmingham district, its merchant mills having to pay heavy freights to the markets. The demand was for Bessemer steel, and iron too high in phosphorus content for this process, such as that smelted from ores of the Birmingham district, was in the discard. The panic in 1893 and the depression that followed added a critical strain; capital was lacking in the South, and one reorganization followed another in the Birmingham companies.

The only salvation was to convert Southern pig iron into steel. Deliverance came from two quarters at once. In 1897 the pig iron industry the country over revived a little, in 1898 the output was up 22%, and another 16% increase by 1899 found resources taxed, and the price rose abruptly. Birmingham foundry iron delivered at Cincinnati sold for $9.33 a ton in 1897, was up 13 cents the next year, and by 1899 averaged $16.58, a gain of $7. By 1902 the price was $20. Just when this grateful rise in the price of pig was occurring, open hearth steel began to be made in the Birmingham district on a large scale. In Nov. 1899, a specially organized subsidiary of the Tennessee Coal, Iron and Railroad Company poured its first steel from ten 50-ton tilting furnaces which had an annual ingot capacity of 300,000 tons. It was established now that Birmingham, turning its basic pig iron into steel by the open-hearth method, could successfully compete in the steel markets; its unusual advantages, once the domination of Bessemer steel was removed, came rapidly into play. The years that followed were marked by the rise of new companies and the consolidation of old ones. The culmination came in 1907. A new and progressive syndicate controlling the Tennessee Coal, Iron and Railroad Company had embarked on the most extensive scheme of steel and iron development the South had known, embracing the construction of a large duplex process steel plant at Ensley, 7 m. W. of Birmingham. By the late fall of 1907, the company had outstanding loans of some $33,000,000, and as a result of the panic of that year the Tennessee Company was bought by the United States Steel Corporation, Nov. 5, for $35,317,632.64.

Twenty-five years ago 70% of the raw foundry iron made in the South was shipped to the North and West, and only 30% was retained for Southern markets. In 1928 less than 20% was shipped out, more than 80% being worked up at home (86% of that of the Birmingham district). The first iron-using plants erected in the South on a large scale were those making water and gas pipe. Soil-pipe plants were soon established. Of the pig iron produced in the South, 50% is consumed by more than 600 grey iron foundries in the section, by far the largest number of which make stoves, radiators, agricultural implements, car wheels and machinery. The smaller number of these foundries, however, the pipe shops, use almost twice as much pig iron as the rest. Thus the iron industry of the South, like the textile manufacture, is no longer confined to crude production, but embraces finer fabrication. Birmingham, in the great variety of its products, is an excellent example.

Cotton-seed Oil.—The cotton-seed oil industry has had a spectacular history. For many years cotton-seed, though known to have value as a fertilizer if spread on the land, was almost entirely wasted. The great heaps of seed which accumulated about the gins constituted a nuisance, having an offensive odour when rotting. Small quantities of oil were expressed from cotton-seed in the South early in the 19th century, but these operations were mostly experimental, and the industry did not begin on a commercial basis until shortly before the Civil War. After the war the manufacture was revived, and was firmly rooted by 1880. In that year about 5% of the seed produced was crushed, whereas in 1926, 80% was crushed, and it is estimated that the industry now produces wealth to the extent of $500,000,000. There has been more combination in the cotton-seed oil industry than in the textile industry, and it has a higher proportion of outside capital (of packers and soap manufacturers, for example), but deflation of the business since the over-expansion just before and during the World War has opened new opportunity for local enterprise. In 1914 there were 882 mills in operation, but since 1922 the number has been less than 600 (570 in 1926).

Though the number of mills has decreased since 1922, the volume of products has, with trifling exceptions, increased. In 1926, 6,305,775 tons of seed were crushed, producing 251,721,354 gal. of oil and 2,840,084 tons of cake and meal; there were 1,854,389 tons of hulls and 1,041,864 bales of linters. In 1925 the average number of wage-earners was 16,215, a large proportion negroes. Products in 1925 were worth $295,685,000, an increase of $69,297,000 over 1923. Texas has three times as many oil mills as any other State.

Furniture.—A new industry in the South is furniture manufacturing. The first plant was built at High Point, N.C., in 1888; by 1900 this State had six small factories with $125,000 capital and products worth $159,000. The Southern States had 312 furniture factories in 1921, 346 in 1923 and 371 in 1925. The leading States are North Carolina, with 13,567 wage-earners in 1925 and products valued at $51,208,238; Virginia, 4,376 wage-earners and products valued at $18,792,297; Tennessee, 2,915 wage-earners and products valued at $9,532,520; Georgia, 2,457 wage-earners and products valued at $7,969,154. The South-eastern States and Virginia produced furniture in 1921 valued at $41,039,000, and in 1925 the product amounted to $89,339,000. All of the States shared in this remarkable increase, but North Carolina in 1925 had three times as many furniture factories (127) as Tennessee, its closest competitor in the South.

High Point is the parent and chief centre. In 1921 the Southern Furniture Exposition building was erected here. This has helped develop a Southern market in rivalry to those at Grand Rapids,

Mich, and Jamestown. N Y The North Carolina Piedmont at the inception of the industry had an ample supply of cheap labour, cheap hardwoods near at hand and excellent railway facilities The furniture manufactured, most of it for Southern consumption, was durable but of inexpensive grades As the labour became more skilled and the cost of raw material increased better grades of product were turned to Good furniture, comparing favourably with that made in the North, now comprises the bulk of the North Carolina output The increase in real wages since the World War, and the spread of instalment buying, have been powerful factors in the prosperity and improved character of the furniture industry in the South as elsewhere. Many Southern factories enjoy a national distribution of their product, and make goods for foreign shipment as well

The Southern Appalachian hardwoods are being rapidly exhausted—the last virgin growth has been entered. While Southern factories get their oak chiefly from North Carolina and eastern Tennessee, and their yellow poplar (used for cores for veneers) from the swamps of the eastern Carolinas, hauls of 500 to 800 m in the supply of lumber are not uncommon In 1909 only 5% of the raw material used in North Carolina came from other States, while in 1919 the amount brought in was 31%. Black walnut and mahogany veneers, coming from the Middle West, are increasingly used Raw materials are now hardly cheaper in the Southern Piedmont than elsewhere, though labour, which is the largest single item in the cost of furniture manufacture, is paid less than in the North It is believed that within little more than a decade the lower Mississippi valley will be drawn upon heavily not only by the Southern furniture industry, but that of the whole country Already methods of economizing on the use of hardwood are used in the South—veneers are more and more employed, and steel and glass are being introduced Waste is being reduced and by-products are being developed

CULTURAL DEVELOPMENTS

It took the South a very long time to recover from the Civil War and the reconstruction governments Worse even than the obvious economic and social effects were the effects on education and on the state of public opinion; provincialism, sensitiveness to criticism from without or within, solidarity of thinking not only about politics but about all other major subjects, a temperamental conservatism that resisted the tendencies of modern life and thought—all these qualities of mind that had become manifest even in the *ante-bellum* period were now accentuated Slowly and surely a more liberal and national point of view, aided by industrial progress and the gradual development of an educational system, has made its way

Despite certain sporadic attempts in some of the States before the Civil War to provide a public school system, it remained for leaders like Atticus G Haygood, J L M Curry, Charles D McIver, Edwin A Alderman, and others in the '80s and '90s to lead a crusade for universal education, as the only genuine basis for a democracy Thomas Jefferson's advocacy of a complete system of public education had borne but little fruit in the section that had accepted him as a political leader, but his ideas were now accepted as the gospel of political leaders like Charles B. Aycock of North Carolina Men came to see that the controversy over slavery and secession and the fatal results that had followed had deflected the South from its true course as defined by leaders who played such conspicuous parts in the early days of the republic Walter Hines Page was one of the first to realize this unfulfilled career of the South and to lay down the programme for the rebuilding of old commonwealths; he and his co-workers in the Southern Education Board and Conference were willing to face the facts of illiteracy and its effect on the poverty, health and efficiency of the masses. They drew contrasts between Western and Southern States not at all favourable to the latter, they found inspiration in the work of Horace Mann in Massachusetts; they fought for the idea that taxation for education was the wisest economy and that the wealth of a State had in trust the social welfare of every human being

These pioneers were followed by men in every State who have worked out in detail a comprehensive plan of education State departments of education have increased from one man, generally a politician, to a body of a dozen or more experts in their respective fields Teachers' colleges and departments of education in universities have been established that bring teacher training within reach of the most backward rural sections School terms have been increased from four months or less to eight months or more, four-year high schools have been increased from 100 in 1900 to 2,500 in 1924, and the students in these schools from 165,000 in 1913 to more than half a million in 1926 Meanwhile, schools have been consolidated, buildings improved, salaries of teachers raised Even negro schools, hitherto supported by outside philanthropy, have received an increasing, though still inadequate, proportion of public funds In North Carolina especially, the State department of education so progressive in its policies, has handled the whole problem of negro education with wisdom and generosity The emphasis on agricultural and industrial training in the Rosenwald schools and at Hampton and Tuskegee extends to the white schools and colleges

In the field of higher education progress had gone on apace In 1895 there were only seven institutions that could meet the minimum requirements of admission laid down by the newly organized Southern Association of Colleges; in 1928 there were more than a hundred that met still higher requirements The various religious denominations, retiring gradually from the field of secondary education, have enlarged their funds for colleges and universities Independent institutions like Vanderbilt, Tulane and Washington and Lee have received large funds from private sources and educational boards Several State universities have received appropriations for maintenance and building that would have seemed miraculous 20 years earlier Duke university, by reason of the benefactions of J B Duke, was in 1929 engaged in a building programme and in the reorganization of the institution that will make it in time one of the outstanding universities of America The university of North Carolina is a striking illustration of the growth of a State university Within 20 years its income grew from less than $100 000 to more than a million, while its building programme has included, among other buildings, a $500,000 chemistry building and a $600,000 library Its faculty

included a score or more of men with national reputations by reason of research they have done. What is true of this university is true, to a less degree, of other universities. The Medical school of Vanderbilt university, the Law school of the University of Virginia, the department of education in the Peabody college for teachers, the department of agriculture of the University of Tennessee, the engineering school of the Georgia School of Technology, compare with the best in America.

The *Sewanee Review,* maintained at the University of the South since 1892, the *South Atlantic Quarterly* established at Trinity college (Duke university) in 1902, the *Journal of Social Forces* at the University of North Carolina, the *Virginia Quarterly Review* at the University of Virginia, the *Southwest Review* at Southern Methodist university, have been organs of liberal thought. Such books as Edgar Gardner Murphy's *The Present South* and Walter H. Page's *The Rebuilding of Old Commonwealths* defined in clear, forceful and courageous words the issues dominant in Southern thought while an increasing number of biographies and histories have given evidence of a scientific and critical handling in striking contrast with the more sentimental books of an earlier period. A growing liberalism is manifest in some of the best newspapers.

Likewise there has been a notable change in the character and quality of creative literature. From 1875 through the '90s, Joel Chandler Harris, George W. Cable, Charles Egbert Craddock (Miss Murfree), Thomas Nelson Page, John Fox and Mary Johnston made full use of the picturesque types, romantic stories and atmosphere of the various parts of the South. The Southern colonel and his lady, the old-time negro, the creole, the mountaineer and the plantation legend were in line with the main tendency in American literature of the period. More recently there has been a marked tendency towards a critical handling of Southern material, even to the point of realism and naturalism. Dubose Heyward's *Angel* and *Porgy,* Julia Peterkin's *Black April,* Paul Green's *In Abraham's Bosom,* Stribling's *Birthright* and *Teeftallow,* Elizabeth Roberts' *Time of Man,* compare favourably with the best contemporary fiction and drama in literary technique and in objectivity of treatment. Especially noteworthy is "the revolt against chivalry in chivalry's old home" as seen in the novels of Frances Newman and Isa Glenn. Better balanced work is found in the stories of Corra Harris and Ellen Glasgow, the latter best representing in a series of novels the transition from the old South to the new. The contrast between the fiction of the two periods is similar to the contrast between the poetry of Henry Timrod and Sidney Lanier and that of John Crowe Ransom, Donald Davidson, Dubose Heyward and other members of poetry societies that have sprung up in Southern cities.

In these and other ways the stubborn individualism of the Southern people is being replaced by co-operative efforts for the good of communities and States. Municipal and State programmes of health and education are being projected. There is still a long way to go. One of the chief hindrances to development in the South is a too facile optimism with regard to actual achievement. There is too much of an insistence on poverty as a justification for delay, too much harking back to a golden age that never was, too much of a tendency to adopt local standards.

The fundamental question is whether the industrial and educational progress now so well under way will result in the loss of regional consciousness and traditions to such an extent that the South will become standardized along with the rest of the country. Will industrial development destroy something that is fine and unique in the Southern temperament and tradition? By reason of its backwardness, due to obvious historical reasons, the South may be able to avoid some of the extremes of modern life and thus make distinct contributions to the nation and to the world.

SOUTH AFRICA, UNION OF. South Africa, geographically, is held to be that part of the Continent south of the middle course of the Zambezi, but for convenience the term is usually considered to be identical with the expression Union of South Africa. The total area is 473,089 sq.m. The Union is divided into four provinces, which consist of the Cape Province, or Cape Colony, covering 276,966 sq.m.; Natal (including Zululand), 35,284 sq.m.; the Orange Free State, 50,389 sq.m.; and the Transvaal, 110,450 sq. miles. Along its northern borders lie Portuguese East Africa, Rhodesia, Bechuanaland and South-West Africa, the latter being mandated territory of the Union. Basutoland, 11,716 sq.m., which is entirely surrounded by the Union, and Swaziland, lying between Natal, the Transvaal and Portuguese East Africa, are not included in the Union. The shores are washed by the Atlantic, and the Indian oceans, the conventional division between the two being the line of longitude, 20° E.

STRUCTURE

South Africa as a whole is an elevated region, over 40% of its area being more than 4,000 ft. above sea-level. The area below 1,500 ft. is practically confined to a coastal strip and to part of the Limpopo valley. The whole region is part of a remarkably stable land block, which has known no serious encroachment of the sea since Devonian times, with the exception of some transgression in the Cretaceous Period in the south, and along the coasts of Natal and Zululand. Since the Triassic Period it has probably been exposed to sub-aerial conditions. In Cretaceous and post-Cretaceous times it appears to have been greatly uplifted. The gradients of most of the rivers are steep between the great escarpment and the coast, and marine deposits, believed to be of Miocene and Pliocene Age, are known to occur up to 1,300 feet above the present sea-level. In consequence, perhaps, of this movement the coast line is remarkably uniform, and there is a striking absence of good natural harbours. A subsequent, but smaller, depression of the land led to the submergence of the coastward ends of the valleys, and produced a series of estuaries, such as those of the Umkomaas, Umzimkulu, Keurbooms and Knysna. The value of these estuaries for shipping has been almost destroyed by the silting action of the rivers, and by the formation of barriers of deposition across their mouths. The smaller ones have in many cases been converted in flat areas of alluvium or marsh.

On broad, topographical lines the country can be divided into an interior plateau, which includes much of the elevated country, and which is bounded by the great escarpment, and the region between the escarpment and the sea.

Much of the interior plateau is formed of Karroo rocks, which are horizontal, or gently inclined. This portion consists of great, undulating plains, broken by flat-topped, steep-sided hills, which are due to the resistance of certain beds of sandstone or sills of dolerite. Good examples of such hills may be seen in the Platberg, near Harrismith, and in numerous hills along the Basutoland border. In the regions to the west and north-west, older rocks outcrop to form more irregular hills, *e.g.*, Magaliesberg, and many small ranges in Griqualand West and Namaqualand. The dolomites of the Transvaal system occur over a considerable extent of country about Pretoria, Rustenberg, Marico and Lichtenburg. They are an important water-bearing series, and here may be found numbers of springs, and the sources of rivers. Between the Asbestos-Kuruman hills and the Campbell Rand escarpment, on the western side of the Dry Harts valley, is a limestone area, forming part of the Kaap Plateau, an area of underground drainage. The highest points in South Africa generally occur about the margins of the interior plateau.

For about 1,400 m. the Great Escarpment can be traced through the Union, bounding the interior plateau, and running more or less parallel with the coast. Different sections are known by various names, such as the Drakenberg in the Transvaal, the Drakenberg or Kahlamba in Natal, and the Transkei and the Stormberg in the north-east of the Cape province, and then, proceeding

westward, as the Sneeuwberg, Nieuweveld, Roggeveld, Bokkeveld and Kamiesberg. Under less well known names it can be traced along the western side of South Africa to beyond the Kunene. For about 1,200 miles its structure is well known, and it can be shown, that it is a feature due to denudation. The degree of boldness of the escarpment is related to the resistance of the rocks which take part in its formation. In the northern and southern portions of the Transvaal section the scarp has been eroded in granite, but in the central part of this section Black Reef Quartzites and dolomites come in, and the height and boldness of the Drakenberg increase with the thickness of these beds. The peak of Iron Crown, near Haenertsburg, reaches 6,964 ft., and Mount Anderson, east of Lydenburg, 7,484 feet Toward Natal stratified Karroo rocks enter into the escarpment, higher and higher beds appearing as it is followed toward the south. The escarpment attains its greatest development between Basutoland and Natal, where it is formed entirely of Upper Karroo beds. The upper part of the Kahlamba consists of about 4,000 ft of lavas, underlain by the Cave Sandstone and other beds of the Stormberg series Several peaks exceed 10,000 ft., as, for example, Giants' Castle, Mont aux Sources, Cathkin Peak, etc. The Kahlamba does not rise in a simple wall Many ridges reach out from it towards the east, and bear witness of its former more easterly situation In this section is to be found some of the finest mountain scenery in South Africa. It is a region of deep, picturesque valleys, which lead up at their heads to great walls of rock, whose tops are weathered and riven into pinnacles and turrets, like some cyclopean castellation The lavas persist for about 280 m, and then disappear from the face of the escarpment in the Stormberg, and are replaced towards the west by successively lower and lower beds, until, in the Van Rhynsdorp district, Nama, and even older, rocks enter into its composition The height diminishes after the volcanics have gone From the Sneeuwberg to the Roggeveld the altitude is generally less than 3,500 feet.

Between the escarpment and the coast lie the Great Karroo and the zone of fold mountains to the south, the south-eastern area to the south-east and the low country in the north-east about the Limpopo river and to the west of the Lebombo range For descriptions of the geological formation of the country *see* the articles on CAPE COLONY, NATAL and ORANGE FREE STATE.

CLIMATE

Owing to its situation in the southern hemisphere, its elevation and its comparatively narrow shape, South Africa is cooler than most places in the northern hemisphere, which are the same distance from the equator The mean annual temperature is remarkably uniform everywhere, because the country, to a large extent, increases in altitude as it decreases in latitude At the meteorological station at Cape Agulhas, 50 ft. above sea-level, and situated 34° 50′ S, the mean annual temperature is 61 5°; at Johannesburg, 5,750 ft and 26° 11′ S, it is 60 6 The highest mean annual temperature is 73°, recorded at Komatipoort, 460 ft. above the sea, and situated on the borders between the Transvaal and Portuguese East Africa the lowest is 54·7° for a station on Table Mountain (Cape Town), 2,496 ft The area with a mean annual temperature of 71° is confined to a coastal strip of northern Natal and Zululand, and to the low veld of the northern and eastern Transvaal Ocean currents affect the temperature of the coastal districts Along the west coast flows the cold Benguela current, and Port Nolloth, 29° 16′ S, has a mean annual temperature of 57·5°. The effect of the warm Mozambique current along the east coast is to be seen in the mean annual temperature of 70·8° for Durban, 29° 57′ S

Mean temperatures, however, are liable to mask important differences, which exist in the climates of South Africa. Both the annual and diurnal temperature ranges increase with distance from the sea, with altitude, situation and with dryness of the atmosphere. The differences between the mean temperature of the hottest and coolest months is 12° at Durban, 15·8° at Pietermaritzburg, and 25·6° at Kimberley, which is 340 m from the coast, and over 4,000 ft. above sea-level. A range of 25° shows the effect of local situation at Weenen, which is only 80 m from the sea, and 2,840 ft. in altitude, but which is situated in a large, saucer-shaped hollow. Places in the Karroo also experience great ranges of temperature, because of the intense dryness of the atmosphere. The diurnal range is a very marked feature of the climate of South Africa, particularly inland Sudden falls of temperature often take place at sunset, especially in the dry season They may also be caused by a sudden change in the direction of the wind. Extremes of temperature are liable to occur. In the summer months the thermometer may rise to over 100°, even at places more than 4,000 ft above sea-level Cases of sunstroke are curiously rare, even though no special precautions, such as the use of pith helmets, may be taken to guard against it. Apart from the lower regions of the north-east Transvaal, parts of Zululand and a narrow belt of country along the coasts, the whole of South Africa is liable to frosts, though the number of these, and their severity, vary from one district to another Ground frosts may occur in the Karroo, even in summer.

The rainfall is very variable both in the seasonal amount, and in the time at which it falls In general it decreases from east to west Durban receives a little over 40 in. per annum, Ladysmith 27·31, Prieska 9·75 and Port Nolloth 2 17 inches Topographical features, of course, produce local variations In Natal the edges of escarpments facing the sea often form well-marked mist belts in the summer months In the Cape Province the contrast between two flanks of a mountain range is often very sharp For instance, George has a rainfall of 34 36 in, while Ezeljagt, 12 m away, but on the landward side of the Outeniqua range, has only 14 98 inches The highest rainfall, so far recorded, occurs in the mountains near Paarl, where several stations receive about 200 inches This, however, only applies to a small area, and is not representative of South African conditions In the Cape Province, out of a total area of 276,966 sq m 177 677 have a rainfall of from 5 to 15 in per annum In the Orange Free State, the total area of which is 50,389 sq m, 32,660 receive 15–25 inches. In the Transvaal, 70,764 sq m, out of a total of 110,450, have an annual rainfall of 15–25 inches In Natal, 21,231 sq m out of a total of 35,291, receive 25–35 inches, while a further 14,060 sq m have an annual amount of 35–50 inches

Over the greater part of South Africa, most of the rain falls in the summer months (October to March, inclusive) If an irregular line be drawn from near East London in a westerly direction to near Laingsburg, then northward through Fraserburg, and curving north-westward to the coast, about 23° S, the area to the north and east of it is one that receives at least 60% of its rain in summer Part of it receives over 90% of its total amount during these months The south-west of the Cape Province is a region of winter rains The area, lying to the west of another irregular line, drawn from about Bredasdorp, at first northward, and bending north-westward to meet the coast at 25° S, has 60% or more of its rain in the winter months Between these two areas is one where the rain is distributed fairly evenly throughout the year. At some places near the south coast, these rains may be appreciable in quantity, and here patches of forest occur.

In the summer rainfall area, much rain falls during thunderstorms, the downpour often being very violent, causing much loss of water by run-off, and much soil erosion Such storms are more characteristic of the inland districts. In the southern Karroo five or six thunderstorms a year are recorded. at Johannesburg, 61. At the latter station lightning is seen on the average on 114 days every year. Precipitation during thunderstorms is often in the form of hail, which falls in the Transvaal on from 80 to 133 days in the year Much damage is often done; crops may be entirely beaten down and ruined, small stock may be killed, and many roof tiles and windows broken Snow falls principally in the mountains, especially along the great escarpment. Along the Basutoland section it may be seen even at midsummer. On Table Mountain (Cape Town) it falls about one year in six. In Natal it is rarely, if ever, seen below 4,000 feet.

South Africa is a land of intense sunlight, which is related to the clearness of the atmosphere, itself connected with high altitudes and dryness. The average amount of bright sunlight received each day throughout the year is 7·51 hours at Cape Town,

8·7 at Johannesburg, and 9·41 at Kimberley. With these figures may be compared the 3·8 hours for London. Evaporation is correspondingly high. The evaporation from a free water surface at Johannesburg is 74·67 inches per annum. This again diminishes the value of the rainfall to vegetation.

VEGETATION

Owing to the small rainfall and high rate of run-off and evaporation, South Africa is poorly supplied with forests. The country is covered with grasses, or, in the drier parts with low xerophytic shrubs and bushes. The grassland is best developed in the eastern half of the country. Three varieties of it are generally recognized: (1) The High Veld, which includes most of Basutoland, the Orange Free State, and the southern Transvaal, is a steppe region, with thorn trees growing on the rocky slopes. The dominant grass is the red grass (*Themeda triandra*). Species of Andropogon, Panicum and Digitaria are also common. Herbaceous perennials are common. In the summer months the veld is in many places made beautiful by innumerable pink, white and mauve flowers of cosmos, which has spread among the indigenous flora. (2) The Eastern Mountain Grassland occurs along the slopes of the Stormberg and Drakensberg at altitudes of from 4,000 to 8,000 feet. The characteristic grasses are species of Andropogon, Heteropogon, Panicum and Themeda. They all grow in tussocks and tufts. In this zone the bracken fern (*Pteris aquilina*) and composites are common. Tree ferns grow near the streams, and in some areas numerous, but scattered, protea bushes occur. (3) The Eastern Grass Veld is found over a strip of country extending between the great escarpment and the coast belt, from about Port Elizabeth northward through Natal, at heights ranging from 1,000 to 4,000 feet. The broad monotony of the grassland is broken in places by low trees or bushes, which occur either individually or in small clumps. Among these are various species of thorn trees (*Acacia spp., Zizyphus mueronata*), the Cape lilac (*Ehretia hottentotica*). Aloes flourish on dry, rocky sites. On many slopes facing the north, the grassland is replaced, owing to intense insolation, dryness and exposure to hot winds, by an assemblage of thorn trees, aloes and euphorbias.

Desert or semi-desert associations cover much of the west and south: (1) Between the fold mountains of Cape Colony and the Escarpment, Karroo vegetation extends from the Olifants river, in the west, to about the Sundays river in the east. The rainfall is from 5 to 15 in. per annum. The plants include succulents, such as Mesembryanthemum, Euphorbia, Aloes, Pelargonium, Stapelia, etc.; low shrubs, like the Karroo bush (Pentzia incana), and compositae. There are many bulbous and tuberous plants, which bloom for a short time after rains. Trees grow only along the dry river courses and on the mountain slopes in the east. (2) The upper Karroo comprises part of the interior plateau, south of the Orange river, and west of a line from Queenstown to Fauresmith, and the eastern part of Bushmanland. This, too, is a treeless area. The vegetation consists of small shrubs and low bushes. The most conspicuous of the succulent plants is Mesembryanthemum spinosum; aloes are common; grasses also occur, among the commonest being Aristida scabrivalvis, Eragrostis truncata and E. obtusa. (3) Namaqualand: this botanical province includes part of Bushmanland, Little Namaqualand and most of Great Namaqualand above 2,000 feet. The rainfall is 5–10 inches. Tufted grasses grow on the higher plateaux and on sandy plains, but scattered, drought resisting shrubs and bushes, with succulents in the lower valleys and on rocky slopes are perhaps more characteristic. (4) The Namib extends northward in a belt 18–35 m. wide along the west coast from Olifant's river. This area experiences the most arid conditions in South Africa, the rainfall being from 1 to 5 inches. On rocky hills grow species of Mesembryanthemum, Euphorbia virosa, Aloe dichotoma, etc. On the sand-dunes a few tufts of grass are to be found—Eragrostes spinosa, E. cyperoides—together with Mesembryanthemum Marlothi, and ganna bush (*Salsola Zeyheri*). Where underground water can be reached the naras flourish (*Acanthosicyos horrida*) and the tamarisk (*Tamarix articulata*). The gravel plains are the most barren of all. In places only an annual Mesembryanthemum occurs; in others only lichens. Welwitschia mirabilis is found in a few places. The characteristic plant is the Bushman's Candle (*Sarcocaulon Burmanni*).

Forest covers only a small proportion of South Africa. Most of the patches, in which it occurs, are to be found in the eastern and moister half: (1) Along a sub-tropical coastal belt from Port Elizabeth through Natal proper, and widening when traced northward through Zululand, was formerly a low forest which in Natal and in much of Zululand, has largely been destroyed and replaced by sugar plantations. (2) Along the slopes of the Drakensberg and Stormberg, and on the ridges which extend from them, patches of forest occur at altitudes of from 3,000 to 8,000. They are generally found on slopes, which face between south-east and south-west, and which are therefore turned toward the rain-bearing winds, and away from the hot, desiccating winds. (3) In the Cape Province forests grow on the seaward slopes of the Outeniqua, Langkloof and Zitzikamma mountains. In all these patches of forest the trees are mostly evergreens. They include the yellowwoods (*Podocarpus latifolia, P. elongata*), black ironwood (Olea laurifolia), assegai wood (*Curtisea faginea*), white pear (*Apodytes dimidiata*), black stinkwood (*Ocotea bullata*), etc. In the sub-tropical regions species with tropical affinities occur. Here are to be found the umzimbiti (*Milletia caffra*), flat crown (*Albizzia fastigiata*), red ivory (*Rhamnus Zeyheri*), etc. In the Cape forests the witels (*Platylophus trifoliatus*) is well represented.

Many trees of foreign origin have been introduced, and grow well in the country. The black wattle of Australia (*Acacia decurrens var. mollis*) is cultivated on a large scale in the midlands of Natal, where its plantations cover over 200,000 ac., and in parts of the Transvaal. The gums are now widely spread in plantations, about farms and along the streets of many towns. Oak trees are planted for ornamental purposes and to provide shade. Well-grown examples line the streets of Stellenbosch, George, Kokstadm, etc. In Natal, and in parts of the high Veld, the beautiful jacaranda tree is grown, while some of the streets of Durban are lined with flamboyants, which are definitely restricted to the sub-tropical districts.

Scattered bush occupies much of the northern, central and eastern regions of South Africa. (1) The East Coast bush occurs along a narrow littoral strip from East London to the north of Natal. It is dense, and has many climbing plants. The trees rarely exceed 30 ft. in height. The most characteristic plants are the palms (*Hyphaene crinita,* and *Phoenix reclinata*) and the wild banana (*Strelitzia augusta*). Other common trees are the red milkwood (*Mimusops caffra*), Kafirboom (*Erythrina caffra*), Amatungula (*Carissa grandiflora*), white pear (*Apodytes dimidiata*), etc.; aloes also occur. (2) The Limpopo bushveld covers much of the basin of the Limpopo in Portuguese East Africa, southern Rhodesia, the Transvaal and south-east Bechuanaland. Most of it lies below 3,000 feet. This is a park-like country. The trees, which are from 30 to 50 ft. high, are fairly well spaced with bushes and shrubs growing between them. In the east many of the trees are evergreen, but toward the west deciduous trees are common. Among the components of this bush are the baobab (*Adansonia digitata*), mahogany (*Afzelia quanzensis*), mopane (*Copaifera mopane*), and several species of acacia. Palms grow near the rivers and vleis. Toward the south the bush is less luxuriant where it merges into the High Veld. (3) The Kalahari Thorn Veld extends over much of central South Africa as far as the Orange river. It is well developed over a great part of Bechuanaland and the Damara plateau. It consists of bush and scattered trees. The dominant tree is the camel thorn (*Acacia giraffae*), but several other species of acacia also occur. The chief grasses include species of Eragrostis, especially E. superbus, Aristida, Pennisetum, etc. (3) The scrub, or Macchia, in the south-west of the Cape Province is found throughout the area bounded on the west by the Olifants river, by Van Stadens mountains on the east, and on the north by the Cedarberg, Cold Bokkeveld, Hex River mountains, Zwartberg and Elandsberg. Its chief components are low bushes and shrubs, from 1 to 6 ft. high, with small dull greyish green, leathery leaves. Among them are species

of Proteaceae, Ericaceae, Restiaceae, Thymelaeaceae, etc Large tracts are covered by the rhenoster bush (*Elyptropappus rhinocerotis*). Bulbous and tuberous plants belonging to the Iridaceae, Liliaceae and Oxalidaceae are common (*See* CAPE COLONY.) The Cape flora appears to be more closely related to that of south-west Australia than to that of the Mediterranean area.

FAUNA

Zoologically South Africa belongs to the Ethiopian region, and is characterized by the absence of bears and deer, and by the presence of a great variety of antelopes, which range in size from the diminutive blue buck or mipiti to the eland. Some of the more strictly tropical forms are unrepresented, such as the gorilla, chimpanzee and many of the parrots Some animals, as for example the lion, crocodile, and some antelopes, have a continuous distribution from the Sudan, along the East African corridor between the great equatorial forests and the coast belt down to South Africa On the other hand the country may be regarded as a distinct sub-region of the Ethiopian area on account of a number of forms which are peculiar to it Among these are the springbuck, black wildebeest, the long-tailed sugar bird, which appears to have a distribution closely related to that of the Proteaceae, and a great variety of insects, adapted to the Cape flora. Since the white man entered the country with his rifle, his enclosures and his domestic animals, the numbers of the larger native animals have been enormously reduced. A few species like the quagga have become extinct Several species of buck only survive in a semi-domesticated state on some of the large farms, or in game reserves. The white rhinoceros, which occurs about the sources of the Nile, and which used to be common in the area between the Zambesi and the Orange rivers, is now represented only by a few individuals about the Umfolosi in Natal The elephant still survives in the Knysna forest, the Addo bush and the game reserve in the north-eastern Transvaal and in Bechuanaland, and a herd of about 400 mountain zebra is preserved in Cape Colony.

Of the rodents there are about 150 species, including squirrels, hares and porcupines Two species of Insectivora—the golden mole and the elephant shrew—are peculiar to South Africa. The Edentata include the scaly ant-eater, and the aardvark, or ant-bear, the structure of whose teeth (molars) has no analogy among the mammals Several species of whales are caught in South African waters The primates are not well represented, but monkeys are found in the forests, and baboons are common in nearly all the mountainous areas. Of the Carnivora the leopard is still fairly secure in some of the mountain kloofs: lions are confined to the northern Transvaal, and the Sabie game reserve. Several of the smaller Felidae—wild cat, lynx, spotted serval, etc.—are moderately numerous Hyaenas are becoming scarce, but the Canidae are still well represented by the black-backed and striped jackal and the wild, or Cape, hunting dog.

Over a thousand species of birds are known including migrants such as the European swallow, red-backed shrike, white stork, curlew, etc. Parrots and hornbills reach from the tropics to Damaraland on the west, and on the east through Natal to the Knysna forests. The jackass penguin, which breeds in large numbers on the islands of the south and west coasts, represents an antarctic element. Eagles, kites, falcons, harriers, hawks and owls occur. The secretary bird, with its long legs and terrestrial habit, is related to the eagles and hawks, and is protected on account of its reputation as a snake-killer. It is peculiar to South Africa. Among the birds which are shot for sport or food are the francolins (locally known as pheasants and partridges), guinea fowls, sand grouse, ducks and geese. The ostrich still exists in the wild condition in unenclosed parts of the country. The common European starling is rapidly spreading about Cape Town and in the coastal parts of Natal; the Indian mynah is well established, and is pushing away some of the native species.

The reptiles include over 350 species. The crocodile does not occur south of the Kunene and Tugela rivers. Tortoises and especially lizards are numerous. Snakes are represented by 125 species. Among these are the puff and night adders, cobra, python, and the swift and deadly imamba (*Dendraspis angusticeps*)

There are 200 species of fresh-water fish By far the commonest are representatives of the carp family, known in South Africa as barbel. The tiger fish (*Hydrocyon lineaties*) is the finest indigenous sporting fish, and occurs in the Komati and Crocodile rivers. There is only one native species of eel, it is confined to the rivers flowing into the Indian ocean Brown, rainbow and Loch Leven trout have been acclimatised, and many rivers in the cooler parts of the country are well stocked In Natal they do well above 4,000 ft. South Africa has many varieties of scorpions and spiders Of insects, it is estimated that there are at least 40,000 species. Those of the north-eastern and eastern districts have affinities with central Africa Mention can only be made of the mantis, or Hottentot god, the white ants or termites, which are often destructive of timber and trees, of the bees including honey bees, which are common, of several types of mosquitoes, including the anophelene mosquito, and the tsetse fly (*Glossina*)

POPULATION

The population of South Africa is divided as indicated in the following table —

	Cape	Natal	O F S	Transvaal	Total
Europeans (1921)	650,609	136,838	188,556	543,485	1,519,488
Europeans (1926)	706,137	158,016	202,985	608,022	1,676,660
Natives (1921)	1,640,162	1,139,804	421,978	1,495,869	4,697,813
Percentage of total pop	58 91%	79 74%	67 11%	71 65%	67·80%
Asiatics	6,498	141,336	100	13,405	161,339
Mixed and Others (estimated)	485,024	11,142	17,151	32,253	545,548
Total (all races)					6,928,580

By Europeans is implied persons of European origin, without any infusion of Bantu, Hottentot, Indian or other blood The term native is applied to the Bantu tribes "Mixed and Others" implies persons who are the result of crosses between Europeans and Bantu, Hottentot, Malays, etc, as well as Hottentots and Bushmen, who would, however, probably not number more than a few thousands. The Asiatics consist chiefly of people brought over as coolies from south India, and of Mohammedan traders Between 1911 and 1921 the Europeans increased by 19 06%, Natives by 16·89%, Asiatics by 8 89% and the Mixed and Others by 3 73% (*see* other articles on Basuto, Hottentots, etc) —

Density of Population per sq. mile (1921)

	Cape	Natal	O F S	Transvaal	Total
Europeans	2·35	3 88	3 80	4 02	3·22
Total (all races)	10·05	40·51	12·67	18·90	14·67

The distribution of the native population is very uneven, especially in the Cape, where the range is from about one person per sq m. or less, in the western and northern districts, to over 70 in the King William's Town district. (*See* CAPE COLONY.)

The white population increases very slowly as the result of immigration. During the years 1922–26 the average yearly number of white immigrants, intending permanent residence, was 27,586, and the corresponding number of white emigrants, relinquishing domicile, 25,635 The country had therefore a net yearly gain of 1,951 settlers, or one person per 242·4 sq. miles In 1926 the number of Asiatics relinquishing domicile exceeded that of permanent immigrants by 1,611.

An important element of the white South African population is formed by the "poor whites," whose numbers in the rural districts are estimated at 100,000 to 150,000. Several causes operate to produce this depressed class. In the rural areas men may lose their hold on the land as the result of drought or disease, or of the fractioning of the farms among descendants, according to the

Roman-Dutch system of inheritance. Most of them are imbued with the idea that all manual labour is "Kafirs' work." Some of these people drift into the towns, but having no skill they must compete in the unskilled labour market with the low-paid native, with whom their relations are often far from satisfactory, and form a grave social problem. The Government has established several afforestation schemes where the labour is done by "poor whites" on a piece-work basis. From the afforestation settlements suitable men are drafted on to irrigated areas, where they are trained to work land under discipline. Labour colonies have been established, to which a man who is habitually idle can be committed from one to five years. Nearly all the unskilled and most of the semi-skilled work is done by natives, Indians and coloured people.

Towns.—The principal towns of South Africa have grown up as seaports—Cape Town (212,997), Durban (151,642), Port Elizabeth (52,298), East London (34,673): in connection with the exploitation of minerals—Johannesburg (288,131), Kimberley (39,702): or as administrative and educational centres—Pietermaritzburg (36,023), Bloemfontein (39,034), Grahamstown (14,909), Pretoria (74,052). The other centres are usually small country towns, which have grown up in most places about a church, and have become market and social centres for the surrounding country. They are nearly all laid out on a rectangular plan, with broad, straight streets, often lined with trees, and sometimes with runnels of water flowing along them, as in Stellenbosch, Graaff Reinet, Kokstad, etc. Homes of wood and corrugated iron are often replaced by stone or brick. Roofs are of iron, slates and where there are no severe hailstorms, tiles. The towns were originally surrounded by commons for pasture. In some cases these have been built over, but they still exist about the smaller towns. Every municipality is obliged, by the Natives Urban Areas Act, 1921, to provide housing for its natives.

Health.—The country is on the whole a healthy one. Diphtheria is liable to occur at some places in winter, and bacterial dysentery is fairly frequent in summer. Enteric, which used to be so common, has been greatly reduced by improved sanitation, and water supply. Leprosy is not uncommon among the native peoples, though the extent to which it occurs in the native reserves is not accurately known. It appears to be most prevalent in the Transkei. In 1922 there were 2,474 lepers in the Union. They are segregated in six settlements—Robben Island (Table Bay), Emjanyana (Transkei), Inkambati (Pondoland), Amatikulu (Zululand), Pretoria, and Bochem (Transvaal). Malaria is endemic in the lower areas of the north and east Transvaal, and Zululand. In some years it becomes epidemic over much of the Transvaal, except the High veld.

ECONOMIC CONDITIONS

Economic.—Up to 1870 South Africa was entirely a pastoral and agricultural country. The discovery of diamonds at Kimberley in 1870 marked the beginning of a new period. General railway construction began in 1874 and was accelerated by the gold rush of the '80s. In 1892 Johannesburg was linked with the Cape ports, and in 1895, with Durban. Farming was for a time neglected in favour of prospecting, but eventually farmers returned with increased capital. The mining areas provided a market for agricultural products. The chief industry was wagon-making. After the Boer war, state departments were formed to deal with agriculture, forestry, irrigation, geological survey, and mining. The World War, by making imported goods scarce, gave an impetus to small industries.

The South African railway system is well organized and efficiently worked. In 1926 there were just over 12,000 miles of line belonging to the State, and 400 m. privately owned. The standard gauge is 3 feet 6 inches. From the principal ports railways run to the Witwatersrand and Pretoria, and there are a number of cross connections. The elevation of the interior plateau increased the difficulties of constructing and working the railways. The escarpment everywhere necessitates a steep climb. The sparse population and the aridity of much of the country are further handicaps. Along the main lines where there is a large amount of traffic some sections have been electrified. To cope with the rush of maize from the High Veld after the harvests, and with the heavy coal trade towards Durban, 171 miles of Natal's main line, from Glencoe Junction to Pietermaritzburg have been electrified. The suburban lines about Cape Town are also being converted. Narrow gauge branches serve some districts. They often follow very tortuous courses. Also, there are motor services, under the control of the railway authorities. In June, 1926, there were 45 of these routes, totalling 2,500 miles. The railways are in the main single tracked. The coaches are nearly all of the side corridor type, convertible into sleepers. The roads of South Africa are still largely undeveloped.

Stockbreeding.—The industry has been handicapped by various animal diseases. In 1896 rinderpest swept through the country and in some districts carried off 90% of the cattle. Future outbreaks could probably be checked at the beginning by modern methods, and precautions. Of greater importance at the present time are diseases caused by certain species of grass ticks. Among these is East Coast fever, which in 1906 was nearly as destructive as rinderpest had been. It has become endemic. War is being waged on the ticks, and all cattle are dipped at short intervals, so that the disease is now held in check. Anthrax is also not uncommon. Since the second Boer war great improvement has been wrought by the introduction of good European bulls. The basis of the South African herds is the old Afrikander breed, which probably has a strong infusion of oriental blood, as is witnessed by its distinct hump. This type has been crossed with various European breeds—shorthorns, Devons, Frisians, etc. There are also a considerable number of pure bred herds of good quality. Most of the cattle owned by the natives are of inferior or "scrub" type. The following figures apply to the year 1926:

	Cape	Natal	O.F.S.	Transvaal	Total
Cattle . .	3,351,269	2,152,100	1,955,772	3,055,140	10,514,281
Woolled sheep	18,927,421	1,890,761	10,340,465	4,219,097	35,377,744
Other sheep .	2,927,569	248,040	139,685	327,198	3,642,501
Angora goats	1,700,070	31,578	72,071	27,609	1,831 328
Other goats .	4,163,826	1,101,254	90,711	800,395	6,156,183
Horses . .	361,278	106,529	265,748	154,096	887,651
Mules . .	86,963	10,472	14,822	26,199	138,456
Asses . .	394,687	78,314	54,416	266,766	796,183

By far the majority of the cattle is concentrated in the moister, eastern half of the country. Since the Act of Union, 1910, there has been a great development in the dairying industry. In 1898, cheese, butter and substitutes were imported to a value of £387,474: in 1918 butter and cheese were produced in sufficient quantities to satisfy the home market, and to export a quantity valued at £122,667; creameries and cheese factories have been established, and an export trade is being built up.

Sheep farming is important in the eastern part of the Cape Province, in the Orange Free State and the higher parts of the Transvaal. Sheep are to a large extent excluded by aridity from the western parts of the country, and by heat and diseases from the low parts of the Transvaal and Natal. The original type of sheep, which is still bred in considerable numbers, is the hairy long-eared, fat-tailed variety. Many English and Dutch breeds have been introduced, as well as merinos from Spain and Australia. Goats thrive in regions, in which the pasture is too poor for sheep. They are bred largely in the Karroo and to a considerable extent in the Orange Free State and the Transvaal. Many of them are of the Angora type. The production of wool and mohair for 1925–26 is given in the table:

	Cape	Natal	O.F.S.	Transvaal	Total
	lb.	lb.	lb.	lb.	lb.
Wool . .	91,256,894	7,191,117	51,713,737	17,759,762	167,921,510
Mohair .	7,602,001	52,045	181,967	43,620	7,879,633

The distribution of horses is somewhat the same as that of sheep. South Africa formerly exported horses to India, Australia, and Egypt, but horse sickness is a handicap. The disease breaks out in the moist season, and lasts from about Christmas until the first

LANDSCAPE AND URBAN SCENES IN SOUTH AFRICA

1. General view of Pretoria, capital of the Union of South Africa showing administrative buildings in the foreground
2. Cape Town, second largest town of South Africa, and in the distance, Table Mountain seen from Signal Hill. The mist on the mountain is usually referred to as the "Tablecloth"
3. Magoebus Kloof, characteristic of the landscape in the North Transvaal region where the Boers settled
4. Johannesburg, the chief commercial city in the Union of South Africa, situated among the Rand goldfields on the slope of Witwatersrand
5. West Street, the chief street of Durban, the principal seaport of Natal. Shown are the library and the museum on the left and the post office on the right
6. Groote Schuur, Capetown, the house built and bequeathed by Cecil Rhodes for use as the residence of the prime minister of South Africa

frosts. The lower areas suffer most severely. Basutoland, and the adjacent parts of the Orange Free State appear to be unaffected. The sickness with the decreased demand for horses has somewhat reduced horse-breeding.

The South African horses are related to the thoroughbred, and have a certain infusion of Arab blood. As a rule they are small, owing to insufficient feeding in winter and during times of drought. Heavy types are beginning to be used for draught purposes in the towns, and to some extent in the wine-growing districts. The mule is popular as a transport animal. It suffers from horse sickness, but to a less extent than the horse. It is largely used in Zululand, and in the south-west of the Cape Province, especially about Malmesbury. The ass was originally imported from the Cape Verde Islands. It is used for draught purposes, where the horse and the ox are debarred by disease, or lack of pasture. Ostrich farming was formerly a very profitable industry, centred about Oudtshoorn. It attained its greatest development in 1913 when there were 776,313 birds in the country. As a result of the Great War, and the change of fashions, the number had fallen in 1926 to 104,578.

Agriculture.—There is naturally a large variety of agricultural productions in a country where the climate and topographical differences are so great. In the south-west of Cape Colony, an area of winter rain, the products are of the Mediterranean type, and include grapes, peaches, apricots, pears, citrus fruit, and wheat. (*See* CAPE COLONY) Wheat is also grown in the eastern districts of the Orange Free State. In the sub-tropical coast-belt of Natal and Zululand, and in the northern Transvaal many sub-tropical fruits are grown, such as pine-apples, papaws, bananas, mangoes, and much citrus fruit. The coast belt of Natal is almost entirely devoted to sugar plantations. Some tea is grown along the north coast of Natal. Tobacco is cultivated in the Transvaal, in the Rustenburg, Megaliesberg and Piet Retief districts, and in Cape Colony about Oudtshoorn, Swellendam, Stellenbosch, and the Paarl. The staple grain crop is maize, which is grown widely in the country. Gradually, however, there has come to be defined a maize area, in which rain falls in sufficient quantity, at the proper time, and in showers of the requisite intensity This area embraces part of the southern Transvaal and much of the Orange Free State, excepting the dry, south-western region.

The annual production of maize varies with the seasons. In the year 1924–25 the total production was 4,859,116,000 lb ; the following year it was 2,183,983,000 lb. Kafir corn (sorghum) is a potential forage and grain crop in areas where the rainfall is too uncertain for maize. It is the favourite grain of the native cultivator, and is used in the brewing of native beer. The grain is also being used as a food for cattle and poultry. In 1925 the total production was 487,305,000 lb. This fell in 1926 to 150,548,000 lb. (*See* also NATAL, TRANSVAAL and ORANGE FREE STATE.)

Conditions do not appear to be favourable to irrigation. The flow of the rivers is very variable and many river channels have been cut well down below the level of the surrounding country. There are, however, several irrigation schemes in existence, as for example the Hartebeestpoort, about 25 m. west of Pretoria, in connection with which there are about 40,000 ac. of irrigable land, Lake Mentz (Sunday's river) 38,000 ac., Tarka (tributary of Great Fish river) 35,000 ac., Kamanassie river 27,000 acres, Grass Ridge (Great Brak river) 20,000 ac., etc.

Industries.—The South African customs are of a protective character, but rebates of duties are granted in favour of Great Britain and those parts of the empire, such as Canada and New Zealand, which have afforded reciprocal treatment. By an arrangement with Portuguese East Africa and the Transvaal the products of the soil of both territories may be freely exchanged; and goods may be imported to or exported from the Transvaal by way of Portuguese East Africa under practically the same conditions as obtain in the Union ports. Under an agreement of 1925 Northern and Southern Rhodesia consent to apply the scale of customs operative in the Union, reserving the right to continue certain rebates on British empire goods. Agreement was also made for the free exchange of the products and manufactures of the three parties, subject to certain restrictions on potable spirits, tobacco, beef and cattle. The agreement was not to apply to that part of Northern Rhodesia which falls in the Congo basin.

For the purposes of trade statistics, Basutoland, the Bechuanaland Protectorate, and Swaziland are treated as integral parts of the Union of South Africa. In 1926 imports of various classes, including Government stores, but excluding specie, were valued at £72,598,157: of this amount, manufactured articles, the principal items being textiles, were valued at over £56,000,000 and food and drink at £7,268,442 The exports from the Union in 1926, of South African products, excluding specie, were valued at £72,324,241. The products of mines were estimated to be worth £47,668,153, and the agricultural and pastoral products £21,314,301.

The principal metal in point of value produced in South Africa is gold, of which in 1926 the output was 9,954,762 fine ozs., valued at £42,285,139 All of this came from the Transvaal Next in value were diamonds, £10,683,597, almost entirely from the Cape Province and the Transvaal. Coal was mined to the extent of 13,734,463 tons, chiefly in the Transvaal (7,593,468 tons) and in Natal (5,159,549 tons). 981,333 fine oz. of silver were produced in the Transvaal. Among the other mineral products, mention may be made of 14,097 tons of asbestos (£216,466), 5,996 tons of corundum (£44,871), 4,951 ozs. of platinum (£93,307), and 1,785 tons of tin (£310,899), all almost entirely from the Transvaal; and 9,235 tons of copper (£494,852) from the last-named province and the Cape.

Various industries, mostly on a comparatively small scale, are growing up in the country to supply the local market. These are largely concerned with the preparation of foods and drinks and the manufacture of vehicles (wagons, etc), furniture, boots and saddlery, bricks, tiles and cement, chemicals, etc. The total number of factories in South Africa in 1925–26 was 7,085 They provided employment for 75,987 Europeans and 117,435 non-Europeans, and produced materials valued at £91,536,926. The average wage paid to European workers in 1924–25 was £239, and to non-European employees £49

The following figures will give some indication of the direction and nature of South Africa's overseas trade in 1926

A.—IMPORTS

From	Value £	Chief constituents
Great Britain	35,501,000	Cotton and piece goods, apparel, machinery and cutlery, railway material.
U S.A.	11,384,000	Motor cars, mineral oils, machinery, cotton goods.
Germany	4,540,000	Railway material, hardware and cutlery, fencing material, electrical material, iron pipes; cotton goods, musical instruments.
India	2,582,000	Bags, rice, teak, paraffin wax.
Canada	2,075,000	Motor cars, agricultural implements, wheat, paper.
Australia	1,910,000	Wheat and flour; railway sleepers.
France	1,431,000	Silks; haberdashery and millinery, apparel and slops.
Belgium	1,265,000	Railway material, cotton goods, fencing standards.
Sweden	1,196,000	Wood, paper.
Japan	1,117,000	Silk and cotton goods.
Holland	1,107,000	Condensed milk, fertilizers, cotton goods.

B —EXPORTS

To	Value £	Chief constituents
Great Britain.	46,010,000	Gold, diamonds, wool, mohair, sugar, fruit.
India	7,661,000	Gold (£7,373,487), silver, coal.
France	3,354,000	Wool, hides and skins.
Germany	2,482,000	Wool, wattle bark and extract, skins
U.S.A.	1,963,000	Skins, wool and mohair, diamonds.
Holland	1,483,000	Diamonds, wool, whale oil
Belgium	1,443,000	Wool, diamonds, wattle bark.
N. and S. Rhodesia	1,320,000	Food and drink, cigarettes, explosives
Australia	566,000	Maize.

The Weights and Measures Act, No. 32 of 1922, embodied the principle of the optional use of Imperial or metric standards. In practice the use of English measures is nearly universal, with the addition in some areas of the morgen (2·11654 ac.), the muid (about 3 bushels), the leaguer (126½ gal.), etc. The official time is the standard time of the 30th meridian east of Greenwich.

Education and Universities.—Education for white children is compulsory between the ages of 7 and 15 (16 in Cape Province and Orange Free State). Primary education is free. The medium of instruction in the lower standards is the home language, either English or Afrikaans. All education except university education, is under the control of the provincial councils, and different systems are in use in the different provinces.

South Africa has four universities. The University of South Africa has its headquarters in Pretoria, and includes internal and external students. It has six constituent colleges, situated at Pretoria, Potchefstroom, Bloemfontein, Pietermaritzburg, Grahamstown, and Wellington.

Also, there are the University of Cape Town, of the Witwatersrand, at Johannesburg, and the Stellenbosch university. The latter is said to specialize in agriculture and theology.

Language.—South Africa has two official languages, English and Afrikaans. The latter is derived from the Dutch of the 17th century, which was brought out by the early settlers, who were largely discharged soldiers and sailors. The vocabulary is somewhat limited, and the structure considerably simplified to meet the ordinary requirements of a rural population, and to be intelligible to the Bantu and Hottentots in its service. It is now being taught in practically all the schools in the country. An Afrikaans translation of the Bible is being undertaken. In 1921, of the total European population of the Union, over 7 years of age, 50·71% spoke both languages, 25·16% spoke only English, and 23·79% only Afrikaans.

Religion.—The following figures will indicate the relative importance of the different religious organizations in 1921. They represent the percentage of each denomination of the total European and non-European population.

	Dutch Churches	Anglican Church	Presbyterian	Congregational	Methodist	Lutheran	Church of Rome	Baptist	Hebrew	Heathen and no religion
European . .	55·21	19·35	4·94	·7	6·76	1·26	4·03	1·02	4·09	·21
Non-European .	5·11	7·77	2·14	2·7	13·50	4·47	1·52	·44	..	44·42

The Dutch Reformed Church is divided into four provincial synods. Also, there are the Reformed Church of South Africa and Die Nederduits Hervormide Kerk. The Anglican Church has its own constitution, important decisions requiring the concurrent assent of all orders of the Church—bishops, clergy and laity. The seat of the archbishop is at Cape Town. The province is divided into twelve dioceses. The Roman Catholic Church is organized into nine vicariates. (R. U. S.)

CONSTITUTION OF THE UNION OF SOUTH AFRICA

In accordance with the provisions of an act of the British parliament (South Africa Act, 1909), Cape Colony, Natal, the Transvaal and Orange River Colony were united under one Government in a legislative union under the British Crown. The Union of South Africa, as the new State is named, was established on May 31, 1910. Upon its formation the colonies named became provinces of the Union. In the case of the Orange River Colony its title was changed to Orange Free State Province. The colonial legislatures were abolished, provincial councils, with strictly subordinate and delegated powers, were set up, and provincial administrators (local men) replaced the various governors. (*See* SOUTH AFRICA: *History*.) The main provisions of the constitution are as follows:—

The Executive and Legislature.—The Government is vested in the king but is administered by a governor-general. He can dismiss ministers and dissolve both houses of the legislature simultaneously or the House of Assembly alone. He can appoint a deputy to act for him during absence. He is paid £10,000 a year and is advised by an executive council, whose members he nominates. The council must include the ministers of State; and departments may not exceed 11 in number. Ministers cannot hold office for more than three months unless they sit in parliament. The control of native affairs is vested in the governor-general, who also deals with Asiatics.

The Senate consists of 40 members, 8 from each province, and 8 members nominated by the governor-general. Four of these are selected for their acquaintance with "the reasonable wants and wishes" of the coloured races. The presence of both nominated and elected members in the Senate is a novel provision in British colonial legislatures. The senators chosen in 1910 hold office for ten years. After 1920 the Union parliament may make any alteration it sees fit in the constitution of the senate (up to 1928 no change had been made). A senator must be a British subject of European descent, must be 30 years old, be a voter, have lived for five years in the Union, and, if an elected member, be possessed of immovable property within the Union of the clear value of £500.

The House of Assembly consists (as originally constituted) of 121 members (now increased to 135). Of these members the Cape Province returns 51, the Transvaal 36 (now increased to 50) and Natal and Orange Free State 17 each. As population increases the total number of members may be raised to 150.

Members must, like senators, be British subjects of European descent, they must be qualified to be registered as voters and have lived for five years within the Union. A general election must take place every five years, and all polls must be taken on the same day. There must be a session every year.

The qualifications of parliamentary voters are those, which existed in the several colonies at the establishment of the Union, save that "no member of His Majesty's regular forces on full pay" can be registered as a voter. As the franchise laws in the several colonies differed, the qualifications of voters in the provinces differ also. In the Transvaal and Orange Free State provinces the franchise is restricted to white adult male British subjects. In neither province is there any property qualification, but a six months' residence before registration is required. In Natal (*q.v.*) there is a low property qualification. In that province coloured persons are not by name debarred from the franchise, but they are in practice excluded. In the Cape Province, where there is also a low property qualification, no colour bar exists and there are a large number of Kaffir voters. (*See* CAPE COLONY: *Constitution*). Parliament may alter the qualifications for the vote, but no law which would deprive coloured persons in the Cape province of the franchise can be effective "unless the bill be passed by both houses of parliament sitting together and at the third reading be agreed to by not less than two-thirds of the total number of members of both houses."

The provinces have no original authority, possessing only such powers as are delegated to them by the parliament. In certain cases the governor-general must reserve the royal assent to bills, *e.g.*, any bill abolishing the coloured vote in the Cape Province. (For proposals to alter the franchise *see* p. 60). The king is given the power to disallow any law within a year of its having received the assent of the governor-general.

With regard to bills the two houses are not in a position of equality. Bills appropriating revenue or moneys, or imposing taxation, must originate in the House of Assembly and may not be amended by the Senate. If a bill passed by the Assembly has been twice rejected by the Senate, provision is made for a joint sitting of both houses, when members vote and decide upon the measure concerned as one body. In the case of a money bill rejected by the Senate a joint sitting to decide its fate may be held in the same session in which the Senate has failed to pass the bill. Every minister of State may sit and speak in either house, but can vote only in the house of which he is a member. Re-election is not necessary on the appointment of a member as a minister of State. Members are paid £700 a year, £3 being

deducted for every day's absence during the session.

The Judicature.—A Supreme Court of Judicature for South Africa was created at the establishment of the Union. The former Supreme, High and Circuit Courts of the several colonies then became provincial and local divisions of the Supreme Court of South Africa, which consists of two divisions, namely the Supreme Court and the Appellate Division. Appeals from the decisions of the provincial and local divisions of the court and from those of the High Court of Southern Rhodesia, must be made to the appellate division of the Supreme Court Unless special leave of the privy council be obtained there can be no appeal from the decisions of the Appellate Division, save in admiralty cases. This restriction of the power of appeal to the privy council is much greater than are the restrictions upon appeals from the Commonwealth of Australia, where appeals to the privy council lie by right from the several State Supreme Courts. The difference arises from the fact that the Commonwealth is a federation of States, whereas the Union of South Africa is but one State with but one Supreme Court. One result of this unification of the courts of South Africa is that any provincial or local division of the Supreme Court in which an action is begun can order its transference to another division if that course be deemed more convenient Moreover the judgments of each provincial division can be registered and enforced in any other division. The administration of justice throughout the Union is vested in a minister of State. As prosecutor, each province has an attorney-general appointed by the governor-general.

Among the general provisions of the Constitution the most important is that both the English and Dutch languages are official languages of the Union and are treated on a footing of equality; all records of parliament, and all notices of general public importance or interest issued by the Government of the Union must be in both languages. (Persons in the public service at the establishment of the Union cannot, however, be dispensed with because of lack of knowledge of either English or Dutch) Other general provisions enact free trade throughout the Union, but the customs and excise, leviable under the laws existing in any of the colonies at the establishment of Union, remain in force unless parliament otherwise provides All persons who had been naturalized in any of the colonies are naturalized throughout the Union. All rights and obligations under conventions and agreements which were binding on any of the colonies have devolved upon the Union.

The harbours of Cape Town, Port Elizabeth, East London and Durban are State owned, as are also nearly all the railways in the Union All revenues derived from these services are paid into a separate fund. The administration of the railways, ports and harbours is entrusted to a board of not more than three commissioners (appointed by the governor-general in council) presided over by a minister of State. Each commissioner holds office for five years and may be reappointed. The board is directed to administer its service on business principles, due regard being had to agricultural and industrial development, etc , within the Union. So far as may be the total earnings are not to be more than are sufficient to meet necessary outlays.

Provincial Administration.—The subjects delegated to the councils include direct taxation within the provinces for local revenue purposes, the borrowing of money (on the sole credit of the provinces) with the consent of the ministry; agriculture (within the limits defined by parliament) and municipal institutions, divisional councils, and other local institutions. The control of elementary education was also guaranteed to the councils up to 1915, and thereafter until parliament otherwise provides.

The councils consist of not fewer than 25 members and not more than the number of members returned by the province to the House of Assembly. Constituencies are single. The qualifications for electors are the same as for parliament, and any person qualified to vote is qualified to be a member of the council. As in the Cape province coloured persons are qualified to vote, they are thus also qualified to be members of the provincial council. Any member of the provincial council who becomes a member of either House of Parliament thereupon ceases to be a member of such provincial council Each provincial council continues for three years and is not subject to dissolution.

The executive power in each province is invested in an officer appointed by the Government and styled provincial administrator He holds office for five years The administrator is assisted by an executive committee of four persons elected from among its own members, or otherwise, by the provincial council on the proportional representation principle The administrator and any other member of the executive committee, not being a member of the council, has the right to take part in the proceedings of the council, but has not the right to vote The provincial councils have not the right to make laws, but ordinances, which must require the assent of the governor-general in council

Law.—The basis of the common law of British South Africa is the Roman-Dutch law as it existed in Holland at the end of the 18th century This was simply the legislation of Justinian, modified during centuries, that is, the foundation of the Code Napoléon The authorities upon the common law in South Africa are, the Dutch commentators upon the civil law, the statute law of Holland, the decisions of the Dutch courts, and, failing these, the *corpus juris civilis* itself

Under British influence in South Africa the law has been modified by legislation and by judicial decisions, and there now exists hardly any material difference between the law of England and of South Africa The law of contracts, of torts, the mercantile law, the law relating to shipping and insurance are practically identical; and even the criminal law is virtually the same. The constitution of the courts is based on the English judiciary, and the rules of evidence and procedure are practically the same All serious cases of crime are tried before a judge and jury, with the same formalities and safeguards as in England, while minor offences are dealt with by stipendiary magistrates. In criminal cases a verdict of guilty must be unanimous. In civil cases either party may demand a jury, a privilege which is seldom exercised; the verdict of the majority here prevails.

The most marked difference between the English and South African systems of law is, as might be expected, to be found in the law relating to real property. In South Africa there is a rigid and universal application of the principle of registration. The title to land is registered, in all cases, and so, with a few exceptions, is every servitude or easement, mortgage or charge upon land There is no law of primogeniture There is absolute freedom of testamentary disposition in the Cape province, and in some other parts of South Africa By the Roman-Dutch law, and in the absence of any ante-nuptial contract to the contrary, there is a complete community of property between husband and wife, subject to the sole control of the husband The courts have, however, the right to interfere in case of any flagrant abuse of this power Ante-nuptial agreements must in all cases be publicly registered By the common law gifts between husband and wife during marriage are void as against creditors This rule cannot be evaded even by ante-nuptial agreement Divorce is granted to either spouse for either adultery or malicious desertion

DEFENCE

Historical.—Before the Union of South Africa was accomplished in 1910, the self-governing Colonies (Cape Colony, Natal, the Transvaal and Orange Free State) maintained defence forces of which the Cape Mounted Riflemen were regulars, the remainder either volunteers or police forces, supplemented by rifle clubs and associations. Acting on the advice of Lord Methuen, commanding in chief the British troops in the country, the various colonial governments took such steps as were possible before union to secure uniformity in military training and organization. After union the question was taken up seriously by the Government in

which General Louis Botha was prime minister and General Smuts the minister of defence, who introduced in 1912 and passed the first Defence Act, under which the first defence forces of the Union of South Africa were raised. A military college was at once established at Bloemfontein to train the staff officers for the new forces which came into being early in 1913. All citizens of military age were then registered, and they volunteered almost unanimously to join the new citizen forces, which were soon to prove the salvation of the country in a rebellion of which the embers were still hot when the World War broke out in August 1914. The story of South Africa's participation in that conflict is told elsewhere. Including about 28,000 coloured and native labour personnel, the Union sent about 221,500 (including over 8,700 officers) in military units to the various theatres of war, the majority serving in West, in Central and in South-west Africa, which was wrested from Germany by a South African Army about 110,000 strong under General Botha. Two other South African Generals formerly in arms against Great Britain (J. C. Smuts and Van Deventer) were successive commanders-in-chief of the operations in East Africa. The South Africans' total war casualties numbered nearly 19,000, of which 14,250 occurred in France, where over 14,050 were killed, wounded or missing and only 194 taken prisoner.

The defence forces at present consist of (a) a permanent force; (b) coast garrison force; (c) citizen force; (d) royal naval volunteer reserve and (e) any special reserve that may be established under the Defence Act.

Recruitment and Service.—Every citizen of the Union is liable from his 17th to his 60th year to render personal service in time of war, in any part of South Africa, in defence of the Union. Not more than 50 per cent undergo peace training, which every citizen is liable to undergo for 4 years, beginning in his 21st year. Volunteers are accepted to do this training between their 17th and 21st year. Those who do no such peace training must become members of rifle associations for 4 years. Wherever facilities for military training can be provided, all boys between the ages of 13 and 17 are required to undergo training as cadets unless their parents object. Members of the permanent force are trained as regulars. Training in the coast garrison force is for 18 to 24 days in a year for 4 years with re-engagements. The active citizen forces do from 22 to 25 days in the first year, from 16 to 21 days in subsequent years. From 10 to 15 days of the training in these forces must be continuous. After 4 years, members pass into the citizen force reserve, class A, and are liable to annual inspection. There is a prescribed course of annual training for compulsory members of rifle associations. The citizen force reserve class B contains all who are not in the other forces or reserves up to the age of 45, and the national reserve all other citizens below 21 and from 45 to 60 years.

Strength, Organization and Distribution.—The budget effectives in 1928 of those permanently employed in the military forces (excluding the air force given below) numbered 1,704, including 73 officers. The total military establishments include 1,471 permanent force, 268 coast garrison force, 8,128 active citizen force, 152,000 in the defence rifle associations and 44,000 cadets. The permanent force includes three batteries of artillery and a regiment of South African Mounted Riflemen, with the necessary auxiliary and administrative services. The coast defence force is divided between Cape Town and Durban. The active citizen force is grouped in units by districts for service in the field, with its reserve class A. The class B reserve is organized in 110 commandos or territorial corps. The defence forces are administered by a ministry of defence, represented by staff officers in the 15 military districts. The Cape Peninsula and Durban are defended ports.

Military Air Force.—A South African air force with a strength of 398, including 109 natives, is included in the military establishments. This force is commanded and administered by a director of air services at defence headquarters and includes a depot, flying school and service squadrons of which one has so far been established. There is also a general reserve of officers and a special reserve of pilot officers with an establishment of 24 for each flight of machines. There are about 100 prepared landing-grounds in Union territory, and steel hangars for about 80 machines at Pretoria. Unlike the other self-governing nations grouped under the British Crown, South Africans are responsible for governing vast numbers of natives, some of them formerly warlike races but now disarmed. This fact is naturally reflected in the organization of the defence forces.

See also the League of Nations *Armaments Year Book* (Geneva, 1928). (G. G. A.)

Naval Defence.—The Cape Colony from 1897 and Natal from 1902, each made small annual payments towards the upkeep of a squadron in South Africa. These payments ceased with the formation of the Union of South Africa in 1910 and during the World War the Dominion relied entirely upon the Royal Navy for its protection at sea. In 1921 the Union Government adopted the principle of forming a South African Navy for Home Defence, but progress has been slow. In 1928 the Union Government maintained a surveying sloop, and two trawlers in commission with a depot ship at Simonstown. These ships have been transferred from the Royal Navy and are manned by officers and men of the South African Naval Service. Simonstown is also the headquarters of the British Squadron on the African Station.

(S. T. H. W.)

HISTORY

Pioneers.—More, perhaps, than to any other man the discovery of the Cape of Good Hope and of South Africa as a settling ground for Europeans is due to the great Portuguese pioneer Henry the Navigator. By him a school of pilots was trained and accurate charts and maps collected which made possible the voyages of Bartholomew Diaz in 1487 and Vasco da Gama ten years later. These two great navigators made known to the world the Cape of Storms, so-named by Diaz, but rechristened the Cape of Good Hope by John II. of Portugal. This discovery inspired in Camoens one of his most celebrated passages in the *Lusiad,* where he introduces the looming Table Mountain:—

> Of such portentous bulk was this Colossus
> That I may tell thee (and not tell amiss)
> Of that of Rhodes it might supply the loss
> (One of the world's seven wonders).

The Portuguese, however, never took kindly to the southern shores of Africa in their voyages to India, especially after an affray with the Hottentots of Table bay in 1510, when one of their viceroys, Almeida, lost his life. They preferred the roadsteads they discovered on the Mozambique coast as harbours of rest and refreshment for their exhausted crews, finding the Bantus of that district more civilized and amenable. When, towards the end of Elizabeth's reign, the Dutch and English began to intrude on the Portuguese monopoly of the Indian trade, both in turn made a trial of the Cape peninsula as a half-way station where their merchantmen could break the six months' voyage to the east. In 1620 two English captains formally took possession of Table bay on behalf of King James: but this action was not ratified, and the English company found in 1651 a port of refuge in St. Helena.

DUTCH COLONIZATION

By the middle of the 17th century the Dutch East India Company had gone far ahead of their English rivals. Until the English conquest of St. Helena they had used that island as their chief stage on the way to the East; but from 1616 their ships had made a practice of putting into Table bay to get fresh water and any fresh meat that could be obtained from the natives, while a primitive form of post office had been established under an inscribed stone, where passing Indiamen collected or deposited letters. In 1648 Leendert Jansz and Nicholas Proot had been shipwrecked in Table bay with the crew of the Haarlem and for five months, till they were picked up by a returning ship, had established friendly relations with the natives, who brought them sheep, cattle and sowing vegetables, which throve amazingly. They presented a report advocating the Table valley as a vegetable garden and storehouse for the East India fleets. The company decided to establish such a station. Three ships were to take out material for building, seeds and implements, and 70 men were to

form a settlement at the Cape of Good Hope.

Jan van Riebeek.—To command the expedition the directors chose Jan van Riebeek (b. 1634), a ship's surgeon, who landed on April 7, 1652. His letters and journal during his ten years' command show ability. The site chosen for the fort was near a swamp where hippopotamuses then wallowed and where Church Square, Cape Town, now stands. The Hottentots were shy of bringing in cattle for sale, and, when they had brought it, developed the habit of stealing it back again; the settlers grumbled, as new settlers do. The directors of the East India Company were troubled at the expense of the settlement, and after three years wished to reduce the number of their servants there to 50, although, as van Riebeek pointed out, the least amount of work required for the settlement to perform its functions at all could barely be done by 120; and, perhaps the hardest trial of all, any commander of a passing fleet belonging to the company superseded van Riebeek during his stay in the Bay, while foreign ships, especially French and English, were a constant source of anxiety.

Small wonder that van Riebeek himself was at times discouraged and in 1655 begged to be promoted to some more honourable post. Nevertheless, during the ten years that he remained his energy was unabated. He despatched expeditions to explore the interior; employed a yacht to good purpose in investigating the coast; encouraged a lucrative seal fishery; built a jetty to facilitate the provisioning of passing ships, and extended the company's area of cultivation as far as Rondebosch, where he built a great storehouse, Groot Schuur.

Van der Stel.—Van Riebeek left the infant colony in May 1662, after giving ample instructions to his successor Zacharias Wagenaar, who founded the present Castle on Jan. 2, 1666 Simon van der Stel, Commander and then Governor from 1679 to 1699, was the second founder of the Cape. Unlike van Riebeek, he was of good family; he loved pomp and circumstance, and elected to end his days in the country, after handing over his office to his son. Van der Stel penetrated with a hundred persons to the copper mines of Namaqualand; another party explored eastwards beyond Oudtshorn, and maritime expeditions were sent round the coast as far as the bay of Natal, which was purchased from the natives in 1689 He also extended the settlement to Stellenbosch, Drakenstein, and beyond Wellington. This extension was rendered possible by the arrival of Huguenot families fleeing from Louis XIV, and by the immigration of young girls from the Dutch Orphan Chamber and of Dutch families organized by the company's supreme Council of Seventeen.

These Dutch immigrants were more pleasing to van der Stel's intensely patriotic soul than the Huguenots, whom he disliked as aliens and for the trouble their independent and uncompromising spirit gave him The annual fair instituted by him at Stellenbosch on the date of his own birthday was the place to see van der Stel at his best. Here he was in the beautiful settlement founded by himself, among people every one of whom was familiar to him. Here he watched them engaging in the old Dutch sports imported from the fatherland, the school children paraded before him and their elders came to drink wine and gossip with him. He himself was a notable farmer and tree-planter. He made the best wine at the Cape, planted trees round his house at Constantia, which are still one of the glories of the peninsula, and had the best crops and the best-fed cattle in the colony.

Growth of the Colony.—At first the company's idea had been simply to have a victualling station at the Cape. Nevertheless, only five years after van Riebeek's arrival, the company found it advisable to allow nine of the settlers' families to establish themselves as independent landowners. But they still were under obligation to take their turn at guarding the fort and were bound to let the company have all the produce they wanted to sell at a fixed price. One result was a continual enlargement of the boundaries of the settlement. The free burghers were always seeking better pastures farther afield. This search had the disadvantage from the company's point of view of stirring up strife with the natives. At first the Dutch only knew of two races of natives, the Bushmen, a tiny race of men in a very low stage of civilization, who lived entirely by hunting and were quite as ready to hunt the tame cattle of the farmers as more savage beasts, and the Hottentots, who were more advanced than the Bushmen; they kept cattle of their own and were able to work in copper; but they were expert cattle-thieves. Thus the settlement was often called upon to repel raids of Hottentots or Bushmen, instead of quietly raising produce for sale to passing ships.

Nevertheless, after the Peace of Nijmwegen of 1678 the company determined to try the experiment of a more vigorous colonizing policy, in the hope of thereby reducing the cost of the garrison and of developing territory which was manifestly productive. German as well as Dutch families were sent out to take up land, and also the Huguenot refugees, some 200, exiled from France by the revocation of the Edict of Nantes. There was some doubt about sending them, since their religion was not of the same form of Protestantism as that of the Dutch and Germans, and because they were not easily assimilated by the Dutch To obviate these objections the Huguenot families were dispersed among the earlier Dutch settlements, their language and separate form of religion being discouraged by van der Stel. This policy was so successful that to-day, though such names as Malherbe, Delarey, de Villiers recall this immigration, there is nothing else to distinguish the families from the Boers. The Huguenots included the most efficient workers of France. Wine-growing especially was brought to perfection by the newcomers, notably in the vineyards of Constantia, where excellent wines are still produced

Cessation of Immigration.—Unfortunately the company still considered that any rights the burghers enjoyed were held merely on sufferance. The burghers had an infinitesimal representation on the Council of Policy at the Cape, and for the sale of their produce they still had to give first option to the company at prices fixed by the officials. The church and schools also were entirely under the control of the officials. Already, too, complaints were heard that the Government gave the burghers insufficient protection in their disputes with the Hottentot marauders in the outlying districts The burghers had, in addition, special grievances against Adriaan van der Stel, the governor who succeeded his father Simon in 1699, inasmuch as he and his subordinates not only appropriated the very pick of the estates, but also competed unfairly with the free members of the community in the sale of produce to the company or passing ships Finally, in 1707, Adriaan was recalled by the company at the same time it was decided that the recurrence of similar troubles could best be avoided by the prohibition of immigration.

Accordingly from 1707 for over a century there was no immigration to South Africa of Europeans; and indeed barely more than 50 years after the Dutch East India Company took over the Cape the supply of fresh Dutch stock, except for a few individual cases, came finally to an end. Thus the Dutch part of the population of South Africa is mainly the result of natural increase since that date It appears that during those 50 years about 2,500 Europeans at most came into the country from overseas, of whom only a half were of Dutch nationality. On the other hand the Dutch had far the largest number of women, which accounts for the German, French and other nationalities being so rapidly absorbed into the Dutch South African nationality. Even so it is remarkable that from this small nucleus of Dutch population has developed the immense preponderance of that race to-day

Ten years after the closing of South Africa to immigration by the Dutch East India Company a momentous decision was taken as to the best method of recruiting the labour required for the farms and other industries at the Cape. The directors sent a series of questions to be answered by the local council as to the means of improving the industrial and financial position of the Cape, the most important being whether it would be advisable to rescind the order prohibiting European immigration or to rely for labour on slaves. Hitherto the climate of the Cape peninsula had proved quite suitable for manual work by Europeans; but unfortunately in the council only one member, the captain of the garrison, de Chavonnes, raised his voice for free immigration and free labour. The arguments of the other members of the council prevailed. Slave labour was cheaper, white labourers were apt to be more troublesome and more touchy on their rights; and the council

paid no heed to the contention of Chavonnes that though white artisans and labourers were more expensive they did more and better work than slaves and above all that an influx of Europeans for service would help to secure a predominantly European population in a country admirably adapted to them, whereas, once slave labour was established, white men would gradually regard it as beneath their dignity to work. So the future fate of South Africa was determined as of a country with two grades of population, the European masters disdaining to do any but the most skilled form of manual work and the hewers of wood and drawers of water composed, not merely of the natives but, since they were often inapt for the work, also of imported coolies from the East Indies or islands of the Indian ocean; a new element which further complicated the already serious racial problem.

Native Opposition.—About 1770, some Boer farmers had reached the banks of the Great Fish river, more than 400 miles to the east of Capetown. Here they found themselves up against the Xosas, the advance guard of the great Bantu race, which for centuries had been making their way down Africa from their original homes in the neighbourhood of the great interior lakes. Physically they were a magnificent race, very different from the puny Bushmen and the uncouth Hottentots. They began their migration southwards as early as the 9th century A.D., and came in spasmodic waves, pushing aside the original inhabitants. There appear to have been three main divisions of them, the more westerly invaders into Bechuanaland, the central wave of Barotse, who remained in the neighbourhood of the Zambesi, and the most formidable of all, the east coast invaders, Tembus, Pondos, Xosas and behind them the Swazis and Zulus north of Natal. By the beginning of the 18th century the Xosas had crossed the Kei river and by the last quarter of it were occupying the Amatola mountains and were found by the Boer pioneers on the further side of the Great Fish river.

Decline of the Company.—The discovery of this formidable obstacle to Boer expansion coincided with the close of the term of office (1751–71) of the last great Dutch governor, Ryk Tulbagh. His 20 years' rule is regarded as the halcyon time of the Dutch company's period, for he was a just and humane man, who repressed the official corruption which had always been one of the standing grievances of the free burghers. But in the time of his successor, Plettenberg, the grievances of the settlers were aggravated. The company itself was in a bad way and, instead of paying its officials properly, winked at their supplementing inadequate salaries by engaging in trade and spoiling the market for the free burghers; the burghers also complained that they had no representation on the Council of Policy which ordered the affairs of the community, and the frontiersmen in the eastern districts had a special grievance in the refusal of the officials to support them adequately in their troubles with the Xosas and other Bantu tribes. Finally in 1795, on the eve of the first British occupation, the farmers of the eastern districts, Swellendam and Graaff Reinet drove away the company's officials and set up a republic.

When the company's rule in South Africa came to an end in this year, after lasting for nearly a century and a half, the settlement had been extended from the tiny fort, vegetable garden and storehouse at the base of Table mountain right up to the Great Fish river on the east and over the Karoo almost as far as the Orange river to the northwest and to the Nieuwveld and Zuurberg mountains to the north. The little party of some 80 servants of the company brought out by van Riebeek had expanded to a community of about 16,000 Europeans, with control over about 17,000 slaves and an uncertain number of Bushmen and Hottentots.

The Boer is a pastoralist and hunter, and by no means inclined to agriculture: for his great herds he required tracts of country, thousands of acres in extent, and he desired to see no country from his rough homestead which he could not call his own. Strangers not of his own race he resented as alien to his ideas. Deeply religious in his simple way, the Boer head of the household read from the Scriptures and led the singing of hymns daily to his family and dependents; while almost the only social pleasure he allowed himself, was once a year when with all his household he trekked, sometimes 100 miles away, to the nearest church for Holy Communion. Objecting to interference by Government officials and regarding himself as the absolute ruler over his own dependents, at the same time he expected help from the Government when he was in difficulties with border tribes.

THE ENGLISH CONQUEST

The Cape was captured after very little fighting by a British land and sea force under Admiral Elphinstone and Generals Craig and Clarke in Sept. 1795, nominally on behalf of the prince of Orange, who had been turned out of Holland by the republican allies of France. In the death-struggle with France it was essential for England not to let this stage on the route to India fall into the hands of the enemy, and until the Peace of Amiens a hold was kept on it for strategic reasons. The government of the generals and governors who acted during the eight years of this first occupation was conciliatory and raised no serious opposition among the Boers. Fortunately there is a very interesting account of society at the Cape during most of this period in the letters written by Lady Anne Barnard, whose husband was secretary of the Government during the terms of office of Lord Macartney and Sir George Yonge. At first there was some trouble with the rebels of Swellendam and Graaff Reinet, and fighting with the Bushmen in the north and the Xosas in the east continued. But at any rate, when the Batavian republic received the country back in 1803, it was in no worse condition than it had been when the English took it over. By this time the company was dead and the Government of Holland succeeded to their charge. Mist, the first commissioner-general, and his successor Janssens introduced several economic, legal and social reforms, but did not stay long enough to see the fruits of their labour: for in 1806 the British sent another force under Admiral Popham and General Baird to wrest the Cape from Napoleon's Dutch allies. With still less fighting than at the first occupation Janssens submitted to the inevitable and once more the British entered into possession. During the rest of the war the administration, except for Lord Caledon's brief term, was kept in the hands of soldiers. Finally by the peace of 1814 England obtained the Dutch colonies of Guiana and the Cape for a payment of £6,000,000; and since then Cape Colony has remained a part of the British Empire.

Lord Charles Somerset.—The first regular British governor of the Cape was Lord Charles Somerset, who remained there from 1814 to 1826. He was autocratic. There was no representative government during his time and the only method of legislation was by proclamation. He antagonized journalists, missionaries and farmers of both races. The farmers he antagonized by a revaluation of their farms and a more strict exaction of their quit-rents, and still more the Boers among them by his institution of a police force composed of natives, whom they regarded as an inferior race who should never be allowed to touch a white man. The culminating grievance with the Boers arose from the refusal of one Frederick Bezuidenhout to appear in a circuit court to answer for his treatment of a Hottentot. When the native police were sent to arrest him he resisted and was killed in the encounter; whereupon his brother, Prinsloo and other friends rose against the Government. The rebellion was easily suppressed, the other Bezuidenhout being also killed in the fighting, while of the survivors 32 were banished and five sentenced to be hanged. The execution of these five at Slachter's Nek in March 1816 was made worse by the bungling of the executioner on the scaffold.

One of the troubles on the eastern frontier had always been the paucity of settlers to resist raids by the Bantu tribes: moreover if the colony was ever to be securely under British dominion, it was important to obtain some settlers of British origin as a counterpoise to the almost wholly Boer population. Accordingly Somerset had little difficulty in persuading the ministry and parliament to grant £50,000 to assist suitable immigrants, with the result that in 1820 no fewer than 5,000 were brought out to settle in the eastern district of Albany round Grahamstown and Port Elizabeth, no attempt being made, as in the case of the Huguenot settlers, to disperse the newcomers among the original colonists and so weld all into one nation. This was the first organized settlement since the Dutch stopped immigration in 1707.

Grievances of the Dutch.—Very little more freedom was given under Somerset's successor. It is true that much needed reforms were introduced in 1828 in the administration of justice, the English criminal system being introduced, while, as in Quebec, civil procedure was left under the Roman-Dutch law. But in carrying out these reforms the Government swept away all the minor Dutch officials such as *landdrosts* and *heemraden*, substituting for them resident magistrates, who sometimes could speak no Dutch, while the old and familiar office of field-cornet was bereft of all its judicial functions. In a word almost all popular share in the government was swept away; nor was there any scope left for municipal government as an outlet for local feeling.

Most of the Boer grievances were connected in some way or other with native policy. In the first place the influence of the missionaries in regard to the treatment of natives was thoroughly distrusted by the Boers. Of the missionaries the most remarkable was the Scotsman Philip, who had much influence with several of the governors as well as with ministers and a large section of the British public at home. His policy was to segregate the natives in reserves under the supervision of Europeans who were to prevent their being tampered with by unscrupulous colonists and teach them to rise to a higher form of civilization. Philip and his brethren were also ready to defend the natives in service from oppression by hard masters. The Boers on their side objected to the policy of reserves, as that would make it more difficult to obtain servants or slaves to work for them. Next they complained of the indecision of the Government in dealing with native marauders on the borders, notably after the Kaffir war of 1834–5. Then the governor, D'Urban (*q.v.*), had established British sovereignty between the Kei and Keiskamma rivers as a precaution against further raids, but was overruled by the colonial secretary Lord Glenelg, who flouted colonial opinion by declaring that the marauders had been more sinned against than sinning Lastly there was the grievance about slave emancipation passed by the British parliament in 1833. The Boers had causes of complaint in the inadequacy of the compensation offered; much of which, too, had to go in commissions to agents who could obtain payment only in London.

The Great Trek.—Missionaries had penetrated to Bechuanaland and Basutoland as well as to Pondoland beyond the Keiskamma river; since 1824, too, a few British traders had attempted to settle on the coast of Natal, but were not encouraged by the Government; and some Portuguese officials and half-caste soldiers clung to the coast line of Mozambique much at the mercy of the fierce Bantu tribes roaming about in their neighbourhood. Chaka the bold chief of the Zulus who had by training and an iron discipline made his fighting force the most formidable in South Africa, was holding, besides Zululand, most of Natal, having driven northward the Shangaans, who then harried the Portuguese settlements and advanced up to Lake Nyasa. A rebellious impi of the Zulus under Umsilikazi had broken off into the country north of the Orange river and then crossed the Vaal, driving the Bechuana clans almost up to the Kalahari desert. The Basutos, another small clan of the Bantus, had established themselves in the mountainous country west of Natal and there under their chief Moshesh, the greatest native statesman of South Africa, had formed one of the strongest native powers, largely by assimilating refugees from other fighting clans. Into this seething welter of warring Bantus a large number of the Boer farmers determined to launch themselves rather than abide any longer under the hated British rule. Between 1835 and 1837 some hundreds of Boers left the colony under various leaders, the most noted being Trichardt, Pretorius (*q.v.*), A. H. Potgieter, Retief and Uys. It was a veritable exodus like that of the children of Israel from Egypt, the heads of families packing all their household goods with their women and children in the great lumbering ox-waggons, beside which they drove their vast herds of cattle and sheep,—indeed we hear of one party of 113 taking no less than £60,000 worth. All started northward into the Free State, as it now is, but soon dispersed in separate detachments, some remaining on the level plateau of that state, others making their way across the Vaal and there again dividing, some to the western lowlands, others as far as the Zoutpansberg mountains in the north-east, while another large contingent crossed the Drakenberg into Natal. All went off "in the full assurance," as Retief wrote, "that the English Government will allow us to govern ourselves without its interference"; but this was just what that Government was not prepared to admit. Under the law as it then stood a man once a British subject could not divest himself of that status. But in practice the parties that settled in the Free State and the distant Transvaal were left to themselves

Annexation of Natal.—It was otherwise with those who entered Natal. Piet Retief was the leader of the band who crossed the Drakenberg into that country, where he found Dingaan, the Zulu chief who had succeeded Chaka, in possession of most of the country but with still a few English traders and an English magistrate established at Port Natal. From Dingaan he obtained a concession of most of Natal, but when he went in friendly guise to his kraal to restore some stolen cattle, he and his unarmed companions were set upon and murdered (Feb. 1838). Dingaan then proceeded to wipe out one of the Boer laagers at Weenen, but finally, after some confused fighting, in which the English from the port helped the Boers, Pretorius, with reinforcements from the Free State, crushed Dingaan at the Blood river in December, a victory still celebrated throughout South Africa as Dingaan's Day. Thereupon a Boer republic was set up at Pietermaritzburg in Natal, which for a time held a hegemony over the republics established at Winburg in the Free State and Potchefstroom beyond the Vaal. It looked as if the hope of Retief, founder of the Natal republic, that he would be undisturbed by the English was to be fulfilled. But though the English Government showed no inclination to pursue its former subjects beyond the Orange and Vaal rivers, the case was altered when the emigrants seized the coast land and port, where British subjects had already settled; all the more when the new republic began to stir up the hornets' nest of native troubles both in Zululand and on the north-eastern border of the Cape. At length, after considerable vacillation in Downing street, English troops were sent in 1842 to garrison Port Natal. Here they were hard pressed by the Boers and would have been forced to yield, had it not been for the famous ride of Dick King to Grahamstown, whereby reinforcements were brought up just in time to save the garrison Thereupon, in spite of another counter-order from Downing street, the governor, Napier, obtained the submission of the Boers, and three years later, in 1845, Natal was annexed as a British possession, while most of the Boers trekked back over the Drakenberg to the republic over the border.

The High Commissioner.—In 1846 the Imperial Government was constrained to recognize its responsibility for events outside the actual colonial limits by instituting the office of high commissioner, whose duty it became to deal with all British interests, not purely colonial, throughout South Africa. Normally this office was combined with that of governor of the Cape.

The chief reason for the annexation of Natal, apart from the fear of an important harbour like Durban falling into possibly unfriendly hands, was that the Boer republic was at that time not strong enough to keep the peace among the swarming hosts of Bantus with which they were surrounded A similar reason led, in spite of Downing street's reluctance, to claims on the allegiance of the other republics north of the Orange and Vaal rivers. The only serious adversaries met at first by those who crossed the Vaal were the Matabele bands under Umsilikazi: but these bands were defeated by Potgieter in 1836 and later by the same leader on the Marico river in the following year, whereupon they fled further north and settled down in Matabeleland Between the Orange and the Vaal the two chief native tribes were the Griquas immediately north of the Orange river and the Basutos further east. The Griquas were formidable chiefly because they were accustomed to the use of European arms and were also specially under the protection of the missionaries who had long been working among them Both the Griquas and the Basutos complained to the high commissioner of their difficulties with the Boers, who were accused of invading their preserves The governor and high commissioner at that date was Sir Harry Smith (*see*

SMITH, SIR H. G. W.), a restless and engaging veteran of the Peninsular War, who began extending British territory in all directions. He added British Kaffraria to the colony and extended its borders northwards to the Orange river. Then, proceeding across that river, he felt that the only way of settling the disputes of the emigrant Boers with the Griqua tribes under British protection was to proclaim the whole district between the Orange and the Vaal rivers as a dominion of the Crown under the name of the Orange River Sovereignty (Feb. 1848). Pretorius, at that time the leader of the Boers in the Winburg district, attempted resistance, but was defeated by Smith at Boomplaats in August, and Warden was left in charge of the new sovereignty. The claim on the allegiance of the emigrants beyond the Vaal, though not enforced, was not relinquished.

Acknowledgment of the Boer Republics.—But this claim over the Boers beyond the Orange and the Vaal rivers was short-lived. Smith indeed had wanted to make British authority effective beyond the Vaal as well as to the south of it, but he was overruled by Downing street, where the cold fit about colonies, reflecting a fairly general view in political circles, was predominant. Accordingly in 1851 two commissioners were sent out to deal with the situation north of the Orange river, and in Jan. 1852 signed the Sand River Convention granting "freedom to manage their own affairs" to the republicans of the Transvaal. Two years later the same liberty was given to those south of the Vaal by the convention of Bloemfontein (Feb. 1854), and the republic of the Orange Free State was instituted. In the same year representative institutions were granted to Cape Colony; in 1856 Natal, hitherto under a lieutenant-governor subordinate to the governor of the Cape, was finally separated from that colony and also granted representative institutions. So by the middle of the last century the four colonies and states which were afterwards to form the four provinces of the Union of South Africa were finally constituted; and the foundations of South Africa as an entity were laid.

Enlargement of Boundaries.—Natal, at the time of its separation from the Cape, was confined between the Tugela and Buffalo rivers to the north and the Umzimkulu river to the south. As a result of the overthrow of the Zulu power in 1880 some Boer settlers took the opportunity of carving out for themselves in 1884 a separate republic of the Vryheid and Utrecht districts, which were absorbed in the Transvaal in 1888 and then finally annexed to Natal after the South African War. The rest of Zululand was formally annexed to the British empire in 1887 and ten years later was incorporated with Natal, which at the same time obtained Tongaland with its port at Kosi bay, coveted by the Transvaal but annexed by the British Government in 1894. The Orange Free State secured new territory on the Caledon river in 1866 at the expense of the Basutos (*see* below). The Transvaal borders on the west, for a long time vague and undefined, were definitely established by 1884. But the limits of the Cape received the greatest extension. By 1847 the border had advanced very little beyond the Great Fish river, to which it had reached at the time of the English conquest. In that year Sir Harry Smith, the most energetic governor the Cape ever had, after a war to punish a raid of the Xosas into British territory, annexed the territory up to the Keiskamma and proclaimed a protectorate under the name of British Kaffraria over the country between the Keiskamma and the Kei, a settlement only finally secured after another war ending in 1853. British Kaffraria was then tenanted chiefly by the Gaika branch of the Xosas and to the north of them by Fingoes, "wanderers" from various tribes all but exterminated by the Zulus and Tembus. Beyond the Kei dwelt the Galekas, the paramount clan of the Xosas, and also the Tembus, another conquering tribe; and thence up to the Umzimkulu, the frontier of Natal, were the Pondos. In 1857, however, occurred a great weakening of the tribes east of the Keiskamma owing to the slaughter of all their cattle by Xosas at the instigation of a fanatical prophet, the Gaikas in British Kaffraria being suddenly reduced by starvation from 105,000 to 38,000; a considerable body of immigrants, including the German legion, disbanded after the Crimea, was introduced to take their place; while in 1865 British Kaffraria was annexed to the Cape. Gradual extensions of British dominion beyond the Kei were made from time to time, generally as a result of Kafir raids on the border settlers, but it was not till 1894 that the Cape Colony borders were made coterminous with Natal by the incorporation of Pondoland. To Cape Colony were added Griqualand West in 1880 and British Bechuanaland in 1895.

The Basuto Wars and Settlement.—Between the Basutos and the immigrants there was trouble over the lands near the Caledon river, the most fertile part of trans-Orangia; Moshesh also interfered with the Bantus to the north-east of Cape Colony. His first serious brush with Europeans was in 1851 when Warden attempted to bring him to account for cattle thefts in the Caledon district but was defeated at Viervoet, while in the following year Cathcart, the governor of the Cape, was also checked by Moshesh near his flat-topped mountain, Thaba Bosigo. But Moshesh was a statesman as well as a commander. He realized that native hosts could not resist a European army that meant business. In the second Basuto War of 1858 the Free State felt the weight of Moshesh's hand; and in the treaty of Aliwal North, mediated by Sir George Grey, he obtained some accession of territory to the south. Again in 1865 war broke out between the Free State and the Basutos. By this time Moshesh was 80 and had lost much of his power and cunning; his people had to yield most of the coveted land south of the Caledon river (the "Conquered territory") to the Free State.

Then, after another short war (the fourth Basuto War), the Colonial Office, yielding to the prayers of the Basutos, in 1868 annexed Basutoland to the British empire. In 1871, when the Cape was granted full responsible government Basutoland was annexed to the Colony. But the Cape "with a population of a third-rate English city spread over a great country," as Rhodes expressed it, was not then fitted for this extra responsibility, and after the fifth Basuto War, which dragged on during 1880–1 and was caused by an unfortunate decision of Sprigg's ministry to disarm the Basutos, at the Cape's own request the Imperial Government resumed control of Basutoland in 1884 and still retains it. Under imperial protection, exercised by a resident commissioner, the Basutos are self-governing, and, in accordance with Moshesh's policy, intoxicating liquor is forbidden in the country, while only a few European missionaries and traders are allowed within its borders by special license.

Discovery of Diamonds.—The discovery of diamonds near the Orange river in 1867 opened a new chapter in South African history. The diamondiferous area, roughly enclosed in an oblong with the Orange to the south, the Hart river to the west, the Vaal to the north and the Orange Free State to the east, had for long been inhabited by Griqua clans under various chieftains of whom the best known were Waterboer and Adam Kok. The Free State had already bought some lands, ill-defined, of Adam Kok, before that chief was transferred with his Griquas to the country between Basutoland and Pondoland (East Griqualand) in 1862. Nicholas Waterboer, the principal Griqua chieftain left, had put himself in the hands of an ingenious attorney, Arnot, who on his behalf claimed practically all the diamond area, to the northern part of which the Transvaal and to the southern the Orange Free State also laid claim. The Transvaal claims were submitted for arbitration to Keate, lieutenant-governor of Natal, and for want of evidence were entirely rejected; the Free State was met with opposition from Waterboer and from the diggers themselves. Finally in 1871 the colonial secretary, although after 1854 his predecessors had specifically stated that England had no interests north of the Orange, authorized the Cape governor, Sir Henry Barkly, to take over the government of the Diamond Fields on the ground that the Crown alone would be able to regulate the unruly crowd of diggers. Arbitration by an outside power, proposed by Brand, the Free State president, was refused; but in 1876 Carnarvon, the next colonial secretary, practically admitted the justice of part, at any rate, of Brand's claim by a payment of £90,000 in satisfaction to the Free State. Griqualand West, as the territory was then named, was administered through a resident until 1880, when it was incorporated with the Cape.

Annexation and Retrocession of the Transvaal: Confederation Plans.—Under Brand's wise and tactful rule the Free State had already entered on an era of quiet but sound prosperity: but it was otherwise with the Transvaal For eight years after the recognition of its independence in 1852 it still contained four separate and discordant governments, which were only unified into one republic in 1860 Even then its constant feuds with native tribes in the north and west had reduced it almost to bankruptcy. The last straw was an unsuccessful war against Sikukuni in the north in 1876, which convinced many of the burghers that almost any issue out of their embarrassments would be acceptable. At this juncture Carnarvon, who in 1867 had piloted the Dominion of Canada Act through parliament, was meditating plans for a confederation of South Africa on similar lines It was not the first time that the idea had been mooted Sir George Grey (*q v*), governor of the Cape from 1854 to 1861, had been deeply impressed by the waste of energy and the constant causes of friction due to the separation of South Africa into four independent communities, especially in the case of native policy which called for an united front from all Europeans. His idea was frowned upon at home and when, as a necessary preliminary to such a movement for union, he responded sympathetically to a proposal from the Free State for re-incorporation with the Cape, he was disavowed (*See* also CAPE COLONY) Now Carnarvon reverted to the idea and the method, and sent up Shepstone, an able Natal official, to the Transvaal with instructions to agree to its annexation if he found any disposition there in that direction Shepstone found a section of the burghers willing to evade their difficulties by this solution; so in 1877 he proclaimed the annexation of the Transvaal. But thereafter everything went awry. Instead of leaving the South Africans to work out their own salvation Carnarvon prepared a scheme himself, chose delegates to consider it and sent out Sir Bartle Frere, a most distinguished Indian official, as governor of the Cape to carry through the measure This in itself awakened suspicion in the Cape, which had only recently obtained responsible government and was very touchy on its privileges The Transvaal soon repented of its change of master, especially since the appearance of the promised representative institutions was delayed As a culmination of calamity the British arms had a serious loss of prestige at the beginning of the Zulu War of 1879, when Chelmsford was routed at Isandhlwana and the Prince Imperial's life was sacrificed through unpardonable bungling, disasters hardly retrieved by the subsequent defeat of the Zulus at Ulundi. In the following year came a change of ministry in England Unfortunately Gladstone's cabinet was divided on the question of restoring to the Transvaal its independence, and did not make the offer of independence under the suzerainty of the Crown until the garrison of Potchefstroom had been forced to surrender to a Boer commando and Colley's force had been wiped out at Majuba in 1881. After this disaster and the retrocession of the Transvaal, which had the appearance of being a surrender to force, British prestige was at its lowest ebb in South Africa and no more was heard of Carnarvon's scheme. By the convention of 1881 the suzerainty of the queen over the Transvaal was safeguarded, but in 1884 Kruger persuaded Lord Derby to drop the term in a new convention, and the only remnants left of British influence over the South African Republic were certain stipulations for civil and trade rights and an agreement that no treaties should be made with other States, except the Free State, without the approval of the British Government.

South-west Africa and Bechuanaland.—A scramble for Africa had now begun and Great Britain thus found herself with a rival power at her very gates. Namaqualand and Damaraland across the lower reaches of the Orange river, although the sphere of the Rhenish Missionary Society's activities, had long been regarded as within the Cape's sphere of political interest, and in 1878 Carnarvon had sanctioned the occupation of Walfisch bay, the best port on the coast. But in spite of an actual invitation from Bismarck, owing partly to the dilatoriness of the Cape ministry, partly to the hesitation of Downing street, the opportunity of annexing the whole territory was foregone, and in 1884 it was taken over by Germany Almost at the same time the Transvaal began to show an inclination to encroach beyond her borders and from the other side to seize the narrow strip of Bechuanaland territory bounded by the Kalahari desert along which the missionaries, Moffat, Livingstone and the rest, had penetrated into the interior; indeed, the only route left for expansion from the Cape northwards Largely owing to the persistence of Cecil Rhodes (*q v*), then beginning his career in the Cape parliament, Cape politicians realized the danger in time The missionary Mackenzie and Rhodes himself were sent up in turn to deal with the intruding Boers, who had actually set up the republics of Stellaland and Goshen over territory clearly outside the Transvaal by the terms of the recent convention, and finally 5 000 men were sent from England to assert British rights and proclaim a protectorate over Bechuanaland This display of force was effective with Kruger and the "missionaries' road" was saved

Rhodesia.—Rhodes had already formed a definite scheme for the utilization of this road. Already in his diamond-digging days he had learned from hunters and missionaries of the rich gold-bearing and pastoral land sparsely occupied by the Matabele since they had been driven north by the early Boer trekkers into the Transvaal By 1888 he had secured a concession from the Matabele chief Lobengula to search and dig for gold in his domain, and in the following year obtained a royal charter incorporating the British South Africa Company to exploit the concession. In 1890 the pioneer expedition to take possession of the rights thus acquired was sent up to Mashonaland, the country east of Matabeleland, but subject to Lobengula's control; and the first settlement was founded at Salisbury An attack in 1893 by some of Lobengula's braves on the settlement at Victoria further south was the occasion for the Matabele War, in which Lobengula was driven a fugitive from his capital Buluwayo, which was at once appropriated by the company as one of its principal stations Again in 1896 the Matabeles rose against the English and this time were joined by the Mashonas, the race they had subjected when they invaded the country from the Transvaal. Rhodes himself, who had resigned his office of prime minister of the Cape after "the raid" (*see* p 58), took part in the operations, and by his courage and diplomatic skill in dealing with the chiefs in their stronghold in the Matoppos secured a satisfactory settlement.

Rhodes and Kruger.—After Majuba prospect of co-operation between British and Dutch was retarded In 1879, partly as a protest against the annexation of the Transvaal, du Toit had founded the Afrikander Bond, with the avowed object of removing the British power and influence entirely from South Africa; its main branch was at the Cape, but branches were also formed in the two republics. Fortunately the Bond soon lost influence in the republics, while in the Cape it lost much of its anti-British savour when the great leader and organizer of the Dutch, J H. Hofmeyr, captured the organization in 1882 with the far less provocative objects of encouraging the use of the Dutch language and training his fellow-countrymen to take an interest in Cape and also South African politics. In these objects he found a strong ally in Cecil Rhodes, who, having founded the great de Beers mining company at Kimberley, first appeared in the Cape parliament in the same year, 1880. Rhodes in his musings at the diamond diggings had elaborated a vision of a united South Africa under the British Crown with a people welded together harmoniously from the two elements, Dutch and English With such a people he hoped to extend British influence throughout the interior of Africa, and as his plans progressed, to effect a junction with the hand stretched out by other British adventurers in East Africa, Uganda and Egypt. In the aim of uniting the races and states of South Africa, at any rate, he was at one with Hofmeyr, and with his support he attained the post of prime minister at the Cape in the same year that he launched the pioneer expedition into Matabeleland. Never have the Dutch and English worked so well together at the Cape as during his sympathetic ministry. But he found an apparently insurmountable obstacle to his larger plans in the antagonism of the Transvaal

The Transvaal was then ruled almost absolutely by President Kruger, who as a boy of ten had accompanied his parents in the

Great Trek from Cape Colony and had never lost the distrust of the English then inculcated into him and only intensified by his dealings with them between 1877 and 1884. Thenceforward one of the chief aims of his policy was to keep his people as far as possible uncontaminated by association with the English or any of their governments. But by an irony of fate this proved the last thing he was able to achieve. In order to be independent of the Natal and Cape ports he had a railway from the Portuguese port at Delagoa bay built by 1894, and in the same year secured the neighbouring native State of Swaziland as a step toward a port of his own at Kosi bay. But Kosi bay was annexed by England, and the Delagoa bay railway could not compete effectively with the railways from the colonial ports. Again in his attempts to secure support from Germany he obtained little beyond friendly gestures, as he found after the Raid and during the South African War. But his worst blow had been the discovery of gold in almost unbelievable quantities on the Witwatersrand in 1886, whereupon the hated English, with Frenchmen, Germans, Jews and others, Rhodes himself among the first, came flocking into the Transvaal to exploit the Eldorado. Though Kruger could not prevent this influx, he at least made it as uncomfortable as he could for the invaders. In spite of the fact that the population of the Rand, almost all foreigners and mostly English, numbered some 80,000, four times as great as that of the Boer citizens, and that it contributed nineteen-twentieths of the public revenue, it was not allowed any voice in the affairs of the State, nor even in the municipal affairs of Johannesburg itself. Moreover their industry was systematically fleeced by the friends of Kruger, many of them Hollanders and Germans, to whom he gave monopolies in dynamite, an essential material in mining, in liquor, whereby they were enabled to debauch the native workers on the mines, and in the transport of coal required for the mining machinery. Indeed the Johannesburgers were appropriately called *uitlanders.* Once, indeed, in 1895, in his anxiety to do injury to anything connected with Britain, Kruger went too far, when he attempted to injure the Cape export trade into the Transvaal and the Cape railways that were competing with his Delagoa bay line, by not only making the rates over the few miles of line in the Transvaal prohibitive, but also closing the drifts to prevent the carriage of goods by waggon from the Vaal. This was a distinct breach of the 1884 Convention and the colonial secretary, Chamberlain, agreed to support the Cape ministry's protest by force, if necessary; whereupon Kruger gave way.

The Jameson Raid.—Rhodes thus determined to encourage and finance a revolution in Johannesburg, and used his position as prime minister and also as head of the chartered company to organize an armed raid into the Transvaal. The raid was to be effected with Chartered Company troopers under the command of Rhodes's great friend Jameson, then administrator of Rhodesia, and there was no difficulty in collecting such a force with adequate secrecy. But there was no suitable jumping off ground for the raid except in a strip of the Bechuanaland protectorate under the control of the Imperial Government. Accordingly, on the plea that it was necessary to have this strip for the projected railway from Kimberley to Rhodesia, Rhodes secured the strip from the colonial office in time for the raid. On Dec. 29, 1895, Jameson rode in with his troopers from Pitsani near Mafeking: but the Johannesburgers were not ready and gave him no support; four days later Jameson surrendered to the Boer commandos called up to repel him.

After the raid Rhodes had to resign his offices and was condemned for his part in it by committees of the Cape and imperial parliaments. But the grievances of the *uitlanders* still remained unredressed and were the occasion for a controversy conducted with growing exasperation on both sides. A direct negotiation between Milner, the new high commissioner and governor of the Cape, and Kruger at Bloemfontein in June 1899 led to the refusal of Kruger of an effective franchise and on Oct. 9 Kruger's Government issued an ultimatum. The course of the South African War is described in the article under that heading.

Reconstruction.—By the treaty of Vereeniging of May 1902 the Boer delegates from both republics agreed to give up their independence; they were promised cash and a loan to repair the ravages of war and full responsible government at any rate before the franchise was given to the natives. Immediately afterwards Botha and other leaders went to Europe to try and obtain better terms from Chamberlain and also to raise a fund on the continent for the Boer peoples; but had little success. The work of reconstruction which affected the whole of South Africa was almost entirely the work of Milner and his devoted staff of young helpers whom he had brought out from England, Milner himself being governor of both the annexed republics, with two lieutenant-governors under him. In the Cape the chief problem was how to deal with the Dutch rebels who in the later stages of the war had joined or openly helped the Boer raiding forces. At one time, indeed, the rebels had appeared to be so serious a danger that it was proposed to suspend temporarily the Cape constitution; but wiser counsels prevailed, and after the peace the rebels were let off lightly with little more than temporary disfranchisement as a penalty. Natal was given the two neighbouring districts of Vryheid and Utrecht, which gave it a firmer control over Zululand. But the great problem was with the old republics. Most of the farms had been destroyed in the course of the long war, while the Boer women and children had been cared for by the British in concentration camps away from their homes. The fighting forces, prisoners of war, women and children had all to be sorted out and taken to their own places; houses had to be built and seed, agricultural instruments and cattle to be supplied; and the schooling which had been provided for the children had to follow them up to their homes. At the earliest moment Crown colony government with a nominated legislative council was established in both colonies; but as the leading Boers would not accept nomination the arrangement was unsatisfactory. Not the least of Milner's preoccupations was to devise a temporary system which should facilitate transition to a hoped for confederation of all the four colonies. Thus for the two colonies of which he was governor he established a common railway system and debt service and a joint constabulary: as high commissioner responsible for all intercolonial affairs he appointed a commission to investigate the whole native problem of South Africa; and in all intercolonial conferences about customs and railway rates agreements he consistently showed a willingness to yield points on behalf of the inland colonies for the sake of harmonious cooperation.

THE UNION OF SOUTH AFRICA

Grey, Carnarvon and even Milner himself had all thought that union would most easily come by a preliminary merging of one or more of the various constituents of South Africa with a more dominant colony: this too had perhaps been Kruger's idea. But the actual method of approach was not found until all the four colonies could meet together as independent entities and on absolutely equal terms. This condition was secured far sooner than almost anyone could have expected by Campbell Bannerman's courage and faith in granting full responsible government to the two new colonies within five years of the peace of Vereeniging. The confusion of four separate governments for a total European population of less than a million and a quarter were obvious. These and other considerations were brought out in a lucid and convincing memorandum largely prepared by Lionel Curtis and his friends and adopted by the new high commissioner, Lord Selborne, who then issued it with a covering letter in Jan. 1907 at the request of Jameson, then prime minister of the Cape. The memorandum was actually published just before the two new colonies obtained responsible government, in January and June 1907 respectively: but, as soon as the new governments had found time to take stock of South African affairs, they heartily agreed with the Cape and Natal in welcoming a national convention to formulate a plan of union. This convention, which met successively at Durban and Capetown and was attended by delegates not only from the four self-governing colonies but also from Rhodesia, lasted from Oct. 1908 to the following February and elaborated the constitution of the Union in very much the same shape as it was finally adopted by votes in the parliaments of all the colonies except Natal, which accepted it by a referendum to all the voters. Passed by the imperial parliament by an act of 1909, the Union

of South Africa was established on May 31, 1910, under the auspices of a new governor general and high commissioner, Lord Gladstone, son of the great statesman who had formerly restored its independence to the Transvaal and himself a member of the Government which had so promptly granted self-government to the new colonies after the war.

Certain characteristics of the Union constitution, due to the special circumstances of South Africa, are noteworthy. Much friction was avoided at the earliest sittings of the convention by the decision to make Dutch, equally with English, an official language. In the last sittings the question of the capital threatened to split the delegates irretrievably; but finally the difficulty of reconciling rival claims was overcome by the ingenious device of making Pretoria the seat of government, Bloemfontein the seat of the judiciary and Capetown the meeting place of parliament, an arrangement which has at least the merit of causing legislators and ministers to travel about the Union more than they would otherwise It was found impossible to devise a uniform scheme of franchise or non-franchise for the natives; so the more liberal system of the Cape in making no distinction of colour, but only of education, was retained and safe-guarded there, while the other colonies kept their own exclusive system. Provision was made for Rhodesia's future admission to the Union on terms to be approved by the privy council, and also for enabling the Union to take over the native protectorates of Basutoland, Bechuanaland and Swaziland, on special terms laid down in a schedule and drawn up in consultation with the high commissioner, but only after obtaining the consent of the Imperial Government, which had special obligations to these territories

The form of constitution adopted was as far removed as possible from that of the Australian Commonwealth, the latest confederation of British colonies before the Union of South Africa. There the aim had been to retain as much of the separate states' particularism as was consistent with any form of confederation. But in South Africa the constitution, as it came from the convention, formulated what was practically a unitary state for the whole of South Africa, with a truly sovereign parliament (subject of course to the purely nominal overriding power of the Imperial parliament), though with certain municipal rights left to the provinces, *i e*, the former self-governing colonies.

Botha's Ministry.—On Lord Gladstone fell the duty of choosing the first prime minister of the Union Government It was a difficult choice, as he had none of the guidance available normally to constitutional rulers from the trend of parliamentary opinion A suggestion had been made that a junction between Jameson and Botha as representing the two main nationalities and parties in South Africa might effectively start the new venture on harmonious lines; but Botha found the idea impracticable. Then the choice lay between Merriman, the grand old man, as he might have been called, of South African politics and Botha, both actual prime ministers of the two leading provinces of the Union, the Cape and the Transvaal Merriman himself and the Cape generally, as the senior colony, thought he was entitled to it. but Gladstone chose Botha, a choice which was amply justified by the event. Botha was successful in securing representatives of all four colonies in his ministry, in which besides himself the other outstanding figure was his *fidus Achates* General Jan Smuts (*q.v.*). It was indeed a party ministry, and at first it was chiefly supported by the Boers with insignificant exceptions

The supreme aim of General Botha was conciliation between the two European races, which he hoped in time to weld into one Afrikander race; he also was determined to abide loyally by the spirit of Vereeniging and, from policy as well as sentiment, attached importance to the imperial connection. On the other hand there were many Boers, of whom the chief representative in the cabinet was General Hertzog, who were afraid of the insidious influence of British ideas, and were determined to keep the old Boer Afrikander strain undiluted. Botha's suggestion of a contribution to the navy at the Imperial Conference of 1911, his willingness to welcome immigration from Britain and his curt declaration that if Great Britain were at war, South Africa would necessarily be involved in it· all these indications awakened the alarm of Hertzog and his adherents, and he gave expression to this alarm in two public utterances that entirely ran counter to Botha's conciliatory policy Since Hertzog would not resign, Botha himself resigned and on being entrusted with the formation of a new ministry in Dec 1912 excluded Hertzog In the following year when the whole subject of policy was brought up at a general meeting of the South African party, while Botha secured the approval of the majority of those present, an appreciable minority, in agreement with Hertzog's views and led by de Wet, seceded Thus Botha was more and more driven into cooperation with the progressive or unionist and mainly British party and lost much support from the backveld Boers

Education.—With two races and two languages, education has been a controversial subject The Boers naturally wished their children to be taught in their own language, at any rate in the early stages, but against that were two obstacles, one that it was difficult to find enough good teachers who were also bilingual for schools where the races were mixed, the other that there was some difficulty in deciding between true Dutch and the *Afrikaans* form of it Before the Union Smuts had introduced a fairly satisfactory compromise in the Transvaal, making the medium of instruction the home language up to the 3rd standard and English as the medium in all except two subjects thereafter; but Hertzog in the Free State had made the mother tongue the medium up to the 4th standard and insisted on more Dutch in the higher standards After the Union, parliament exercised its over-riding right of final decision even in educational questions by setting up a committee to report on the language question, as a result of which a compromise was adopted between the Transvaal and Free State arrangements This report was more or less adopted by the four provinces. Primary education is now compulsory and free for all European children in the Union

Native Policy.—One of the most important reasons for union and one of the most difficult problems to adjust was the elaboration of a consistent native policy uniform for the whole of South Africa The importance and urgency of the problem is evident from the mere fact that in 1911 out of a total population in the Union of 5,973,394 no fewer than 4,019,006, *i e*, 67·3%, were natives, as compared with only 1,276,242, *i e*, 21·4%, Europeans, the remainder of the population being made up of 11·3% Asiatics and mixed races Each of the four colonies had had a different system of administration for this large population of natives. In the Cape ever since 1854 there had been nominal equality between Europeans and educated natives, who enjoyed the privilege of the franchise, and a clause in the constitution specially safeguards this native franchise at the Cape against precipitate abolition by a majority from the other provinces But since Rhodes's introduction of the Glen Grey Act in 1895 the policy of entrusting natives of the Transkeian territories, where there were hardly any European settlers, with a large measure of responsibility for their own affairs, encouraging them to adopt individual tenure of their lands, and at the same time depriving them of the franchise for the Cape parliament, had been greatly extended. In Natal, though theoretically the natives had the same rights to the franchise as in the Cape, in practice only a handful exercised it. the serious rebellion in Zululand in 1906 had brought home to Natal the weakness of its native administration and recently the care of the natives had been entrusted to an expert commission almost independent of parliament In the Transvaal and the Orange Free State the natives were still under the same régime as in the old republics, obliged to hold identification passes, subject to heavy hut-taxes, unable to hold land of their own and mostly confined to ill-defined reserves or to squatting on farmers' lands with much the same status as villeins; in the mining areas of the Transvaal there were also specially stringent pass provisions and enactments as to enlistment and employment of natives. This discordance of policy was recognized as a danger, all the more as with education and a growing tendency among natives to get employment in various parts of the Union and compare notes with one another, those more drastically repressed were beginning to demand the more favourable treatment accorded to others. Above all the feeling that they were being crowded out by a minority

of Europeans from their just requirements in land was causing discontent. A commission appointed by Lord Milner before the Union had already made a comprehensive report on the whole native policy, and many commissions have since been constituted to investigate detailed aspects of the problem. But hitherto the difficulties have been too great to formulate a satisfactory and comprehensive policy for the whole Union. Some reforms however have been introduced. In 1911 a Native Labour Regulation Act was passed to apply to labour districts, similar to the Transvaal mining areas, throughout South Africa, and in some respects making better provision for the welfare of the natives. In 1913 the Natives Land Act merely provided that natives and Europeans should not encroach on one another's lands, but foreshadowed a measure providing that more land should be made available for natives. So far, however, in spite of commissions and committees, the difficulties in giving material expression to this good intention have not been overcome. Useful legislation, however, has been passed in the Native (Urban Areas) Act of 1923 which makes for uniformity in the housing, etc., of natives in locations within urban limits, and still more by the act of 1925, which at last enacts one consistent system for the taxation of natives throughout the Union, while a great step forward was taken by Smuts in 1920 in securing more sympathetic and harmonious relations with the natives by the institution of a special Native Affairs Commission devoted to their interests and the revival of regular conferences with representative bodies of natives.

These measures, owing to the difficulty of finding a generally acceptable solution of the whole problem, have necessarily been of a piecemeal nature. The one serious attempt to deal with native policy as a whole has been put forward in General Hertzog's declaration of policy in 1925. He proposed to abolish the Cape franchise for natives and to substitute for it a system applicable to the whole Union, whereby the natives of South Africa should elect seven Europeans to represent them in the House of Assembly; secondly that additional land should be provided for the sole use of natives and that the system of native councils to decide on their own local affairs, which has been so successful in the Transkei, should be largely extended. The whole tendency of these proposals is, it is evident, to raise even higher the barrier between Europeans and natives, on the avowed principle that the only method of retaining a white South Africa is by preventing either natives or Europeans from trenching on one another's preserves. In 1925, largely in deference to the labour section of his supporters, Hertzog introduced the first instalment of his programme with the bill legalizing a "colour bar," whereby in certain districts natives, and Asiatics too, were to be absolutely prohibited from engaging in any skilled or semi-skilled employment where they might compete with Europeans and be confined to unskilled labour. This bill provoked intense opposition from the natives as also from Smuts's South African party and especially from those members used to the more liberal methods of the Cape: so bitter was the controversy that it was rejected by the Senate in 1925 and only passed into law in 1926 after a joint sitting of both houses. So far the other proposals in Hertzog's scheme, which have also evoked deep suspicion in the natives, have not been passed into law.

Asiatics.—In the Cape province the Asiatic, or Malay community as it was called, dating originally from the days of Dutch rule, has in time fitted itself harmoniously into the rest of the community: and a charming picture it is that Lady Duff Gordon gives in her *Letters from the Cape* (1927) of this community as she saw it in the early sixties. But difficulties have arisen from Asiatics at first (since 1860) imported under indenture from India to cultivate the Natal sugar plantations. There was at first nothing to prevent these Indians, after finishing their indentures, from settling in the country with their families; and they not only did so but began spreading as small traders or market-gardeners into the Transvaal and the Free State. Soon all three colonies began to object to the settlement of this third great race in South Africa, already enough troubled with problems arising from the juxtaposition of Europeans and the sons of Ham. Smuts himself as minister of the Transvaal had already had much trouble with them and their redoubtable leader Gandhi on the very eve of Union. From the outset of the Union Government the trouble recurred in an aggravated form. The question did not merely affect South Africa, for the Indian Government took a deep interest in the complaints of its citizens and the Imperial Government was much concerned at the difficulties experienced by members of one part of the empire in another. But South Africa was determined that no more Indians should be allowed to come into the country and become residents and that those already there should be restricted in their movements. After much disturbance and negotiation with India, the Immigrants' Act of 1913 was passed, which without directly mentioning Indians, stopped their immigration and retained the objectionable £3 tax on those left in the country; this act, however, after further agitation and negotiation with Gandhi, was modified to his satisfaction by the abolition of the tax and other slight concessions. Until 1919 this arrangement held, when the Indians already domiciled in the Transvaal found themselves suddenly deprived of their right to hold property and trade by a Gold law of 1908; while in 1924 the Natal Indians lost the Natal franchise they had hitherto enjoyed, and a Class Areas bill was introduced empowering the government to segregate Asiatics in reserved areas. Once more excitement flared up in the Indian community and in India itself: finally an arrangement was made with representatives from India whereby Indian rights were respected and a distinguished Indian was permanently stationed in South Africa to look after his fellow-countrymen's interests.

Labour Questions and Strikes.—One of the most notable developments since the Union has been the rise of a strong white labour party, with its strength centred chiefly on the Rand. Its programme resembles that of the Australian labour party with its emphasis on the maintenance of a high standard of wages and conditions of labour for all skilled and semi-skilled European workmen and the rigid exclusion of all but these from participation in such work. White labour had many grievances on the Rand and elsewhere that called for redress: trade unions were insufficiently recognized by mine managers; and the havoc of miners' phthisis, owing to inadequate precautions, was alarming. The first outburst occurred in 1913 when a strike occurred on the Rand owing to a dispute between a manager and some miners: for a time Johannesburg was at the mercy of the strikers until Botha and Smuts were forced to call in imperial troops, as the new citizen force was not yet organized. After some casualties a truce was patched up whereby the unions were recognized and remedies for other grievances were promised. But in the following year the trouble broke out afresh with redoubled violence. Owing to a dispute in the Natal coal-fields a general strike was proclaimed which affected not only the Rand but also the government railways. But this time Smuts was ready with his new citizen force. Sixty thousand men were hurried on to the Rand, martial law was proclaimed and within a week all the labour leaders in the Union had been arrested and ten of the chief agitators summarily deported without trial. Smuts's excuse for this high-handed action was "that the Government could not run the ordinary risks of the law-courts"; but he was severely criticized for it not only in England but also in South Africa, where the Government's indemnity bill was hotly debated and was followed by a labour majority in the elections for the Transvaal Provincial Council. Once more in 1922, when Smuts was prime minister he had to suppress a strike on the Rand, partly due to labour troubles, partly to republican agitation, which, owing to its violence, was called the reign of red terror and was not overcome till 10,000 agitators had been arrested. These ruthless, however necessary, repressions naturally led to the persistent opposition of the labour party to Smuts personally and eventually to its junction in 1923 with the Nationalists under Hertzog. Nevertheless both Botha and Smuts during their ministries, which lasted from 1910 to 1924, introduced several improvements in the conditions of labour, such as acts directed against the scourge of phthisis in 1911 and 1919, acts for the security of workmen's wages and for compensation against accidents, and a scheme for arbitration and conciliation in labour disputes, measures which have been further elaborated

by the Hertzog Government. Since the Union also the whole railway system has been unified and the vexatious differential railway rates and customs between the different colonies abolished.

The War and the Rebellion.—When the World War broke out in Aug. 1914 many of the Boers wished to stand out of it altogether, but Botha and Smuts were determined to abide by the empire. They relieved the home forces by offering to dispense entirely with imperial troops and be responsible for South African defence, and further agreed to conquer German South-west Africa. But before doing the last they had to meet a serious rebellion among some of their own people, who wanted entirely to disassociate the country from Britain's concerns. Beyers, the commander of the Defence Force resigned and with de Wet and others collected a force to resist the Government; the commander of the border force went over to the Germans. In this crisis Botha, sorely against his will, decided it was his duty to take the field against his own rebellious Boers; but he and Smuts decided that their suppression must be entirely the work of Boers, for if troops of English origin were employed fresh racial bitterness would surely ensue. Beyers and later de Wet, the two chief rebel leaders were defeated with comparative ease in Oct. and Nov. 1914, and the bitterness aroused was considerably assuaged by the very moderate punishments inflicted on the rebels

Botha was then able to turn his attention to his task of capturing South-west Africa The waterless country rather than the comparatively small numbers of the German troops proved the most formidable enemy in the campaign which lasted from March to July 1915, when the German forces surrendered themselves and their colony unconditionally to Botha. The easy victory was due to fine organization for which Botha and Smuts were responsible.

After this success, South Africa as a whole took no direct part in the war, but no fewer than 50,000 South Africans fought in German East Africa, where Smuts was in command during 1916, while about half as many went overseas to Europe, gaining great honour for themselves and their country in such engagements as Delville Wood and Givenchy; in addition nearly 100,000 Bantus volunteered for work behind the lines in labour battalions. Smuts himself left the East African command only to take a seat in the Imperial cabinet during the rest of the war, while he and still more Botha were notable figures at the Versailles conference, where they signed the Treaty as equal representatives of South Africa with the other allies and dominions.

South-west Africa.—One provision of the treaty attributed to South Africa as a mandatory of the League of Nations the administration of South-west Africa. At first the administration was placed under the arbitrary rule of an administrator, G R. Hofmeyr, assisted by a nominated council of which half the members were Germans. In 1922 the attention of the Mandates Commission of the League of Nations was directed to the methods of the administration in suppressing a revolt of the Hottentot tribe of Bondelswarts, whereby 100 men, women and children were killed, and some strictures were passed on the administrator's policy in the matter. Otherwise the territory has prospered; although about half the 15,000 Germans in the territory at the time of its occupation returned to Germany, some 10,000 South Africans have taken their place and the administration has done much by railway, roads and irrigation to increase the country's prosperity, while a long-standing boundary dispute with the Portuguese Government of Angola was amicably settled in 1926. But before this a demand had come from the European inhabitants for some voice in the administration. Partly elective municipal institutions were granted in 1922, but for a more extended electoral system it was necessary to regularize the position of the Germans, who were still technically aliens Under an agreement negotiated with Berlin by Smuts in 1923, the Germans automatically received British citizenship, unless they elected specifically not to accept it, and in 1925 a regular system of partly representative executive, legislative and advisory councils was established. The territory may ultimately be incorporated in the Union.

Rhodesia, Swaziland and Bechuanaland Protectorate.—A section of the South Africans—and notably General Smuts—was desirous, when in 1922 the British South Africa Co.'s régime in Rhodesia came to an end, to incorporate that country in the Union. The issue was left to the vote of the settlers in Rhodesia, who, in spite of the very favourable terms offered them by Smuts, preferred to have an independent and responsible Government of their own. To this incorporation the Imperial Government would have offered no objection; but it was different with a proposal mooted in 1924 for the incorporation of Swaziland and Bechuanaland, over which the Imperial Government exercised a protectorate. Here the white settlers are few compared with the natives on whose behalf the Imperial Government has undertaken special responsibilities, and, as the natives do not appear to be anxious for the change, it is not likely to be effected in the near future

The Hertzog Ministry and the Flag Question.—Botha, the first prime minister of the Union, died in Aug 1919. On General Smuts, his devoted follower, naturally fell his mantle He had aroused suspicion among the Dutch by his participation in imperial affairs and the lukewarmness attributed to him in supporting the Dutch point of view when it conflicted with that of the British, by his conduct in combating the various strikes on the Rand he had made a bitter enemy of the growing labour party led by Col Creswell In 1920, after a general election he found himself in a minority in the house, and, after one more effort to heal the breach with Hertzog and his Nationalists, he saw there was nothing for it but a junction with the Unionists, who had given general support to Botha and himself since 1914. In 1921 he formed a coalition ministry with them and in the ensuing general election improved his position in the house. At the same time the Nationalists, an entirely Dutch party, and the Labour party, predominantly English, were tending towards an alliance which was practically consummated in 1923 The alarm felt by the Labour leaders at the talk of Hertzog's supporters of a desire to cut adrift from the empire was overcome by assurances from Hertzog. The parties found much in common in their native policies, the Labour party being determined to limit the Kafirs to purely unskilled work, and the Nationalists for somewhat different reasons being anxious to keep them frankly in subjection to the Europeans The most hopeful result of these two alliances, Labour-Nationalist and South African-Unionist, was that parties were not divided on national lines, but each an admixture of Boers and English

Smuts once more went to the country in 1924, after a defeat at a by-election, and found himself in a minority of 27. Hertzog then formed a ministry of Nationalist and Labour elements and introduced the native and labour legislation already described But the measure which stirred the country to its depths and at one time threatened to split the ministerial coalition was the Flag Bill of 1926 To take the place of the Union Jack the Nationalists demanded a new flag for the Union, which should express something of the history of the Afrikander nation and especially the traditions of the old republics. This was only reasonable, but unfortunately in the flag originally suggested practically every symbol of the imperial connection had been eliminated. All those of English blood, including many of the Labour party, were at once up in arms and the controversy was so acute that a decision was wisely postponed for that year. Shortly afterwards followed the imperial conference at which the new and almost independent status of the dominions was defined in a document of which Hertzog, who had helped to draft it, said that it "lays a deep and enduring foundation for national cooperation by members of the British Commonwealth of Nations" But on his return the flag controversy was revived, Natal threatened to secede and opinion was even more enflamed than before, when, by one of those suddenly inspired compromises, by which, before now, South Africans have averted a calamitous breach, the bitterness of the struggle was assuaged, and a place found in the new national flag for the Union Jack to symbolize the strong sentiment for the empire felt by a large section of South Africans.

Characteristics.—The South African census perhaps wisely does not attempt, directly at any rate, to distinguish between the two principal European races in the country. But there is no doubt that those of Dutch origin exceed in numbers those of

English descent. Besides numbers the Boers have two great sources of strength, in their being mainly those attached to the soil as farmers or pastoralists, and also because their sole attachment, the only country to which they look, is South Africa itself. Those of English descent, even when they have made South Africa their only home and look to descendants to live on in that home, have almost invariably a further attachment to the mother-country.

South African literature is dealt with below. In art the greatest achievement of the South Africans is to be sought in architecture, especially that of the old Dutch farmhouses still to be found at the Cape, beautifully adapted to the climate and the needs of the inhabitants—buildings to some extent imitated, but developed for more modern conditions, by the genius of Herbert Baker, the architect of the best modern public and private buildings.

Bibliography.—(Unless otherwise stated, the books etc. referred to are published in London). H. C. Schunke Hollway, "Bibliography of South Africa to 1888" in *Trans. S. African Phil. Soc.* (Capetown, 1898); *Subject Index of London Library* (1909) and *Supplement* (1923); S. Mendelssohn, *South African Bibliography*, 2 vols. (1910). *See* also *The Times History of the War in South Africa*, vol. vii. (1900–09); E. Walker, *History of South Africa* (1928). There are good bibliographies also in Dr. Theal's works; for the Rhodes period there is a bibliography in his life by Basil Williams.

History: H. C. V. Liebbrandt, *Précis of the Archives of the Cape of Good Hope*, 10 vols. (1896–1906): these vols., each under separate title, contain documents dating from Van Riebeek's Journal (1651–62) to 1806; Sir E. Hertslet, *Map of Africa by Treaty*, 3 vols. (1896); Sir C. Lucas, *History of South Africa to the Jameson Raid* (1899); G. McCall Theal, *History and Ethnography of Africa, S. of the Zambesi, 1505–1795*, 3 vols. (1907–10); *History of South Africa since 1795*, 5 vols. (1908–10); *Records of the Cape Colony 1793–1827*, 36 vols. (1897–1905); *Records of South Eastern Africa*, 9 vols. (1898–1903); F. R. Cana, *South Africa from the Great Trek to Union* (1909); Sir G. Cory, *The Rise of South Africa to 1857*, 4 vols. (1910–26; is not yet finished), a carefully edited and well-documented history, of which vol. i. (to 1820) is the best; A. Wyatt Tilby, *South Africa 1486–1914* (1914); G. W. Eybers, *Select constitutional documents illustrating South African history 1795–1910* (1918); *Van Riebeek Society Publications* (1918–26), original reports, journals, etc., of early Cape times; A. P. Newton, *Select Documents re Unification of South Africa*, 2 vols. (1924); *Official year book of the Union of South Africa*, published periodically at Pretoria.

Natives and Missionaries' Work among them: R. Moffat, *Missionary Labours and Scenes in South Africa* (1842); D. Livingstone, *Missionary Travels and Researches in South Africa* (1857); J. M. Orpen, *History of the Basutos of South Africa* (1857); *The Natives of South Africa* (1901) and *The South African Natives* (1909), edited by S. African Native Races committee; D. Kidd, *The Essential Kaffir* (1904); Sir G. Lagden, *The Basutos*, 2 vols. (1909); G. W. Stow, *The Native Races of South Africa* (1910); W. M. Macmillan, *The Cape Colour Question* (1927); A. S. Cripps, *An Africa for Africans* (1927).

Miscellaneous: John Pinkerton (ed.), *Voyages and Travels*, vol. xv. (Thunberg's account of the Cape of Good Hope, 1814); Olive Schreiner, *Story of an African Farm* (1883); Lord Bryce, *Impressions of South Africa* (1897); Lady Anne Barnard, *South Africa a Century Ago* (1901); E. H. Crouch (ed.) *Treasury of South African Poetry* (Capetown, 1907); S. G. Millin, *The South Africans* (1926).

Biographies: Biographies of English statesmen concerned with South Africa, such as those of Gladstone, Ripon, Granville, Harcourt, Chamberlain, Carnarvon, Beaconsfield, Campbell-Bannermann, may be usefully consulted. Among those of South Africans the following may be mentioned:—J. Martineau, *Sir Bartle Frere* (1895); P. A. Molteno, *Sir J. C. Molteno* (1900); *P. Kruger*, by himself (1902); W. D. Mackenzie, *John Mackenzie* (1902); *Sir Harry Smith* by himself (1903); A. Wilmot, *Sir R. Southey* (1904); Sir Lewis Michell, *Life of Cecil Rhodes* (1910); Basil Williams, *Cecil Rhodes* (1921); J. H. Hofmeyr and F. W. Reitz, *J. H. Hofmeyr* (Capetown, 1913); I. Colvin, *Sir Starr Jameson* (1923); E. Walker, *Lord de Villiers* (1925). *See* also the articles and the bibliographies of the separate South African States. (B. Wi.)

SOUTH AFRICAN LITERATURE. The earliest of the books written in or about South Africa were naturally devoted to description of the country and its inhabitants.

The best of those in English is *Travels in the Interior of Southern Africa* (1822) by William John Burchell. Among many later works David Livingstone's record of his early explorations entitled *Missionary Travels and Researches in South Africa* (1857) is of outstanding importance. South African literature proper must be divided into that written in English and that written in Afrikaans.

ENGLISH

The first poet with any claim to be called South African is Thomas Pringle (1789–1834), who spent six years in the country as librarian and journalist. Among his poems the best known are *Afar in the Desert* (1828), which was highly praised by Coleridge; *The Lion Hunt*, and *The Bechuana Boy*. It was some time before any other notable work in verse appeared. A recent anthology, *The Centenary Book of South African Verse* (1925), edited by Francis Carey Slater, contains poems by 68 writers, most of whom are still living. Slater's own poetry is saturated with the feeling of the country to which he belongs. Among his works are *The Sunburnt South* (1908), and *The Karroo and other Poems* (1924). Arthur Shearly Cripps, for many years a missionary in Mashonaland, has written poetry in which the influence of Oxford is blended in a surprisingly beautiful way with that of the country to which he devoted the best part of his life. His poems include *Pilgrimage of Grace* (1912), *Lake and War* (1917); and he has also written stories of life in those remote parts, including *Faerylands Forlorn* (1910), *Cinderella in the South* (1918) and *Lion Man* (1928). Cullen Gouldsbury, for several years a native commissioner in Rhodesia, showed poetical gifts of a high order in his *Songs out of Exile* (1912) and *From the Outposts* (1914). Mary Rosalie Boyd, in her poem *The Veld*, which won the Capetown Bardic Chair in 1921, has finely expressed the fascination exercised by South Africa upon those who come to make it their home. Charles Murray, formerly chief of the Public Works Department, has written some excellent poetry, mainly in a Scots dialect. *Hamewith* (1909), *A Sough of War* (1917) and *In the Country Places* (1920) are among his volumes. Arthur Vine Hall has published his collected poems under the title *Poems of a South African* (1926). Roy Campbell, one of the youngest of South Africa's poets, made a startling appearance with *The Flaming Terrapin* (1924). Among his later poems *Tristan da Cunha* gives promise of more mature work with an increasing feeling of historical atmosphere.

The most famous novel yet produced in South Africa is Olive Schreiner's *Story of an African Farm* (1883), which with all its faults has the stamp of genius. Some of Rider Haggard's most thrilling stories, such as *King Solomon's Mines, Jess* and *Swallow*, belong to South African literature, for they arose directly out of his residence in that country. William Charles Scully, a magistrate in the Cape Colony, has written stories based on a first hand knowledge of native life. *The White Hecatomb* (1897) and *A Vendetta of the Desert* (1898) are among his works. *Margaret Harding* (1911) by Percival Gibbon, and *God's Step Children* (1924) by Sarah Gertrude Millin, deal with the difficult problems arising out of the contact of the white races with the black. Pauline Smith, a young writer born in the district of Oudtshoorn, has published some short stories under the title of *The Little Karoo* (1925), which are marked by a fine sympathy and sincerity.

In history and biography some valuable work has been done. The letters of Lady Anne Barnard belong in a sense to both categories. Though not published till 1901 (*South Africa a Century Ago*) they give a vivid picture of life at the Cape about 1800. An interesting account of the writer is given in Dorothea Fairbridge's *Lady Anne Barnard at the Cape of Good Hope* (1924), which includes much previously unpublished material. Among many later workers the name of George McCall Theal (1837–1919) stands out conspicuously for the untiring industry which he gave to investigating the original records upon which the work of future historians must be based. Sir George Cory's *Rise of South Africa* (1910 *seq.*) deals mainly with the development of the eastern part of Cape Colony, and gives the results of many years of patient research. Another work of outstanding importance is *Lord de Villiers and his Times* (1925), by Eric A. Walker, professor of history in the University of Capetown, who has also written a valuable *History of South Africa* (1928). An extensive literature has gathered round the name of Cecil John Rhodes, including lives by Sir Lewis Michell and Sir Thomas Fuller. Ian Colvin's *Life of Jameson* (1922) and Earl Buxton's *General Botha* (1924) are also of importance. Frederick Charles Kolbe (Monsignor Kolbe), a poet and critic of distinction, has written

a delightful autobiography entitled *Up the Slopes of Mount Zion* (1924). *Education in South Africa 1652 to 1922*, by Ernst G. Malherbe, is a useful survey of an important subject. Among many works dealing with the difficult and complex problems involved in the relations between the Europeans and the natives may be mentioned *Black and White in South-East Africa* (1911) by Maurice Evans; *The Education of the South African Native* (1917) by C. T. Loram; and *The History of Native Policy in South Africa from 1830 to the Present Day* (1924) by Edgar H. Brookes. The views of the natives themselves have found expression in *The Black Problem* by D. D. Tengo Jabavu, and in other works. *A History of Christian Missions in South Africa* (1911) and *Thrice through the Dark Continent* (1917), a record of missionary travel by Prof. J. du Plessis, deal with another aspect of the same subject.

See Mendelssohn, *South African Bibliography* (1910). (H. C. N.)

AFRIKAANS

Afrikaans is the name given to the language spoken and written by the descendants of Dutch, French and German colonists who settled in South Africa prior to the British occupation of 1806. Formerly the language was also known as "Cape Dutch" or "the Taal" (Dutch for "language"). Afrikaans has developed from the seventeenth century dialects of the province of Holland; but though it still agrees very closely with these dialects and with literary Netherlandish Dutch in sounds, syntax, vocabulary and idiom, it shows a striking simplification in its flexional system, having become even more analytic in its structure than English. Isolation from Holland, the almost total absence of conserving influences like schools and literature, the novel surroundings and changed occupations, and the incorporation of numbers of French Huguenots and German immigrants account for the rapid development of a form of speech grammatically as distinct from the Dutch of Holland as Shakespeare's English is from that of King Alfred. There is considerable evidence to prove that Afrikaans had reached its modern form not much later than 1750.

Till quite recently, however, the language employed in writing was modelled on that used in Holland, and particularly on that found in the seventeenth century version of the Bible. Apart from one or two stray rhymes in old newspaper files, a few documents by unschooled writers, and a word-list of 1844, we find no written Afrikaans before 1860. In that year the magistrate of Cradock, Louis Henri Meurant, anonymously published a political dialogue in what was almost pure Afrikaans. Meurant's example proved infectious, and Afrikaans articles began to appear in several newspapers. In 1870 followed the well-known adaptation of Burns' "Tam o' Shanter" ("Klaas Geswint en sy Perd") by F. W. Reitz, afterwards Chief Justice and later President of the Orange Free State. In 1872 a movement in favour of Afrikaans as a written language was initiated by A. Pannevis, with whom C. P. Hoogenhout soon afterwards became associated. In 1875 a society, "Die Genootskap van Regte Afrikaners," was founded at the Paarl with the avowed object of working for an Afrikaans Bible and an Afrikaans written language. After a considerable amount of success with a newspaper (*Die Afrikaanse Patriot*, 1876–1904), a monthly magazine (*Ons Klyntji*, 1896–1905), and a number of other publications, the movement collapsed, largely owing to the fact that its leader, the Rev. S. J. du Toit, began to entertain political views which were not shared by the bulk of the Afrikaans-speaking population. The activities of the "Genootskap" and of the Rev. du Toit cover the greater part of the first period of written Afrikaans (1860–1900). Most of the publications of this period being primarily intended as propaganda among an almost purely rural population were written in very simple language and issued in cheap pamphlet form. A few of them are today still read (*e.g.*, J. Lion Cachet's didactic stories *Die Sewe Duiwels*, S. J. du Toit's historical novel *Die Koningin van Skeba*, and a number of poems like the above-mentioned adaptation of "Tam o' Shanter"); but the vast majority of these have sunk into oblivion. Another author, also entirely forgotten today, is Melt J. Brink, who worked independently of the "Genootskap" and who published a series of humorous farces in an artificial language, a mixture of Afrikaans and Netherlandish Dutch.

The New Generation.—After the Boer War of 1899–1902 the Afrikaans movement was taken up by a new generation, and a second period of activity commenced. A system of orthography more conservative than that of the Rev. S. J. du Toit made the transition from Netherlandish Dutch to Afrikaans much easier, while the publication of the historical novel *Johannes van Wyk* by J. H. H. de Waal (1906) and of poetry of considerable literary merit like *Die Vlakte* by J. F. E. Celliers (1906), *By die Monument* by Totius (1908), and *Oom Gert Vertel en ander Gedigte* by C. Louis Leipoldt (1911), furnished a most powerful argument. Propaganda work was actively carried on in the newspaper press and especially in the monthly magazines *De Goede Hoop* (founded 1903), *Die Brandwag* (1910–1922), *Ons Moedertaal* (1914–1915) and *Die Huisgenoot* (founded 1916). The result was that Afrikaans was introduced in 1914 into the schools; and in 1919 university professorships in this language were instituted at Stellenbosch and Bloemfontein. By the year 1924 all the Dutch Church denominations had adopted Afrikaans as an official language, and an Afrikaans version of the Bible is now being prepared. In 1918 the Union legislature sanctioned the use of Afrikaans as one of the official languages for all purposes except for bills, acts, and other Parliamentary documents, in which Netherlandish Dutch had still to be used. In 1925 this restriction was removed, and since that date Afrikaans has enjoyed full official sanction. An Afrikaans literature, distinctively South African in colour and sentiment, has arisen. Poetry of outstanding merit has been written by J. F. E. Celliers, Totius (J. D. du Toit), C. Louis Leipoldt, C. J. Langenhoven, and A. G. Visser. Most of the poetry is lyrical, but there are a few successful examples in the narrative style (*e.g.*, Leipoldt's *Oom Gert Vertel*).

In prose a great deal has been published. *Uit Oerwoud en Vlakte*, by Sangiro (A. A. Pienaar), depicts in a highly artistic manner the tragedy of animal life in the forests of East Africa and has been translated into English under the title of *The Adventures of a Lion Family*. Novels or short stories have been written by J. H. H. de Waal, D. F. Malherbe, C. J. Langenhoven, Leon Maré, J. van Bruggen and E. de Roubaix—to mention only a few of the best known names. Especially the works of Langenhoven exhibit qualities of style and composition that have made a wide appeal to the Afrikaans-reading public, while those of van Bruggen reflect a psychological insight and literary power of a high order. To dramatic literature some notable contributions have been made by J. F. E. Celliers, J. F. W. Grosskopf, C. J. Langenhoven, H. A. Fagan, C. Louis Leipoldt, and others.

In biography G. Preller's *Piet Retief*, N. J. van der Merwe's *Marthinus Theunis Steyn*, J. P. la Grange Lombard's *Paul Kruger* and J. D. Kestell's *Christiaan de Wet* are the best known works.

The most comprehensive Afrikaans grammars are Botha and Burger, *Grammar of Afrikaans*, and Bouman and Pienaar, *Afrikaanse Spraakkuns*. For the history of the language *see* the article by J. J. Smith in *Official Yearbook of the Union of South Africa 1919–1925*; D. C. Hesseling, *Het Afrikaans* (Leiden, 1923), D. B. Bosman, *Oor die Ontstaan van Afrikaans* (Amsterdam, 1923), and S. P. E. Boshoff, *Volk en Taal van Suid-Afrika* (Pretoria, 1921). The history of the literature is treated by L. van Niekerk, *De Eerste Afrikaanse Taalbeweging en Letterkundige Voortbrengselen* (Cape Town, 1920), E. C. Pienaar, *Taal en Poesie van die Twede Afrikaanse Taalbeweging* (Cape Town, 1926); and P. C. Schoonees, *Die Prosa van die Twede Afrikaanse Beweging* (Pretoria, 1927). (J. J. S.)

SOUTH AFRICAN WAR, 1899-1902. The South African War may be divided into three distinct periods. The first comprises the Boer invasion, terminating with the relief of Ladysmith on Feb. 28. The second ended in Oct. 1900 with the flight of President Kruger. The third consisted of guerrilla warfare on the part of the Boers, met by the blockhouses and punitive columns of the British, which operations were in force until May 31, 1902, when peace was ratified at Pretoria.

Operations in Natal.—The war opened with the investment of Mafeking by a Transvaal force under P. A. Cronje and the envelopment of Kimberley by Free State commandos under Gen. Wessels. But these were minor operations. The main Boer effort was made in Natal, where their forces were commanded by P. J. Joubert, while Lieut.-Gen. Sir George White

was the British commander-in-chief. The northern part of Natal presented two faces of a triangle to the two enemies, the short base being formed by the Tugela river. Close to the head of the triangle at Dundee and Glencoe was posted a small British force under Maj.-Gen. Sir W. Penn Symons. Against this force there advanced a Boer force under Lukas Meyer from the east, and, more slowly, the foremost portion of the main Boer army from the north, while at the same time other Transvaalers descended upon the railway between Glencoe and Ladysmith, and the Free Staters from the passes of the Drakensberg advanced towards Ladysmith, the British centre of operations at which the reinforcements sent from India gathered. On Oct. 20 the Dundee brigade vigorously and successfully attacked Talana hill, and drove back Lukas Meyer, but Symons was mortally wounded, and 226 officers and men were killed and wounded. Half the mounted men lost their way in attempting to pass the enemy's flank and were taken, and the brigade, threatened to its left rear by Joubert's advance and by the force that had seized the railway, only escaped by retreating upon Ladysmith, where it arrived in an exhausted state on Oct. 26. Meanwhile Sir George White had discovered the Boer force on the railway, and, though anxious on account of the advance of the Free Staters, on the 21st, stimulated by the news of Talana, he sent out a force of all arms under Gen. French to drive the Boers from Elandslaagte and so to clear Symons's line of retreat. This was accomplished by French and his subordinate, Col. Ian Hamilton, in the action of Elandslaagte on Oct. 21 (British losses, 258). But on the 22nd the Free Staters' advance caused the victorious force to be recalled to Ladysmith, and the third action north of that town, Rietfontein (24th), was only a demonstration to cover the retirement of the Dundee force. By Oct. 29, all the British forces at the front and their reinforcements had fallen in on Ladysmith, which the Transvaalers on the north and east and the Free Staters on the west side began to invest. Before the junction of the two allied wings was complete Sir George White attempted by a general attack to break up their line. The result of this decision was the battle of Lombard's Kop, outside Ladysmith, in which the whole of the available British force was engaged. The engagement was disastrous to the British, who had undertaken far too comprehensive an attack, and the Natal Field Force was obliged to fall back upon Ladysmith with the loss of 1,500 men, including a large number of prisoners belonging to the left column, who were cut off at Nicholson's Nek and forced to surrender by a mixed force of Transvaalers and Free Staters under Christian de Wet. Two days later Ladysmith was isolated, but not before French had escaped south by train, and the naval authorities had been induced to send into the town a naval brigade with large guns, able to answer Joubert's artillery.

Buller's Arrival.—Gen. Sir Redvers Buller, who had been appointed to the supreme command in South Africa as soon as it was perceived that war was imminent—his force being one army corps in three divisions, the divisional generals being Lord Methuen, Sir W. Gatacre and Sir C. F. Clery—arrived in Cape Town, ahead of his troops, on the day following Lombard's Kop. The situation which presented itself was delicate in the extreme. In Natal practically the whole of the available defence force was swallowed up by the steady success of the invasion; on the western frontier two British towns were isolated and besieged; and Boer commandos were on the point of invading Cape Colony, where the Dutch population seemed on the verge of rebellion. The army corps was about to arrive, practically as a whole unit, in South Africa; but it was evident that the exigencies of the situation, and the widely divided areas of invasion, would at least defer the execution of the plan which had been formed for an invasion of the Orange Free State from Cape Colony. The first duty was to effect the relief of the British forces which had been rendered immobile, and another duty imposed by political circumstances was to relieve Kimberley (where Cecil Rhodes was), while the prospect of rebellion forbade the complete denudation of the central part of the colony. Thus Buller had no choice but to disintegrate the army corps. Clery and some brigades were sent to Natal; Gatacre with less than a brigade, instead of a division, was despatched to Queenstown, Cape Colony; while Lord Methuen, with a division, was sent off to relieve Kimberley. As November wore on, the situation did not improve. Cape Colony was invaded; while in Natal a flying column of Boers, pushing down from the Tugela, for a short time isolated the newly-arrived force under Gen. Hildyard, which opposed Joubert's advance on Pietermaritzburg at Estcourt. The situation in Natal seemed so serious that on Nov. 22 Buller left Cape Town and sailed for Durban.

Failures of Methuen and Gatacre.—In the meantime Methuen had begun his march to the relief of Kimberley. He encountered resistance at Belmont on the 23rd, but drove the Boers out of their strong positions. Two days later he won another action at Enslin. Still persevering he moved on to the Modder, where he was seriously opposed by De la Rey and Cronje, the latter having posted down from Mafeking with 2,000 men and arrived on the previous night. The Boers, who held a river line, kept the British attack at bay all day, but eventually fell back, relinquishing the position after dark, as their right had been turned by Pole-Carew's brigade. It was a long and wearing fight, in which the British lost 485 killed and wounded, and what was more serious, Methuen (himself wounded) found that his force had exhausted its forward momentum, and that he would have to collect supplies and reinforcements on the Modder before fighting his next battle. The extent of the operations and the gravity of the situation now began to be felt in England; every available man was called up from the reserves, and the War Office made what at the time seemed adequate provision for the waste which it was seen would occur. On Nov. 30 the mobilization of a sixth division was ordered, offers of colonial aid were accepted, and every facility was provided for local recruiting. On Dec. 10 Gatacre essayed a night march and attack upon the enemy's position at Stormberg, and, misled by his guides in unknown ground, was himself surprised and forced to return with a loss of 719. On the following day Methuen delivered an attack upon Cronje's position between the Upper Modder river and the Kimberley road, a line of kopjes called Spytfontein and Magersfontein. In a night attack on Magersfontein hill the Highland Brigade was caught under heavy fire while still in assembly formation, and lost its general, Wauchope, and 750 men, and in the battle by day which followed, the total losses amounting to about 950. Buller had collected at Chieveley in Natal a mounted brigade and four infantry brigades.

Buller's Failure. Lord Roberts Sent Out.—On Dec. 15 Buller made his effort and failed. Behind the Tugela at Colenso (*q.v.*) were Louis Botha's forces covering the siege of Ladysmith, and, imperfectly acquainted with the lie of the ground, Buller sent a force to turn Botha's left, in conjunction with a frontal attack. But the flank attack became entangled in mass in a loop of the river and suffered heavily, and two batteries that formed part of the frontal attack came into action within a few hundred yards of unsuspected Boer trenches, with the result that ten guns were lost, with some 1,100 men. Buller then suggested to White the surrender of Ladysmith, believing this to be inevitable and desiring to cover White's responsibility in that event with his own authority; but White replied that he did not propose to surrender, and the cabinet at home, aware of Buller's despondency, appointed Field Marshal Lord Roberts to the supreme command, with Maj.-Gen. Lord Kitchener as his chief of staff. As the formation of a seventh division practically drained the Mother-Country of trained men, a scheme for the employment of citizen soldiers was formulated, resulting in the despatch of Imperial Yeomanry and Volunteer contingents, which proved one of the most striking features of the South African campaign. Pending the arrival of Roberts and reinforcements, the situation in South Africa remained at a deadlock: the three besieged towns—Mafeking, Kimberley and Ladysmith—merely held their own. In northern Cape Colony, French, with two cavalry brigades, kept at arm's length a superior force of the enemy in the vicinity of Colesberg. On Jan. 6 the Boers in Natal tried to storm Ladysmith. The garrison, though weakened by privation and sickness, made a stubborn resistance, and repulsed the attack at Caesar's Camp and Wagon

Hill with severe loss to the enemy, itself having 500 casualties.

Roberts arrived in Cape Town on Jan. 10, 1900. His first duty was to create a field army out of units in Cape Colony. Buller essayed a second attempt to cross the Tugela, by turning the Boer left. But the upshot of several days' fighting was the retreat of the British. They had penetrated the enemy's right centre by the seizure of Spion Kop (*q v.*), but the force there became the target for the concentrated attacks of the Boers, and, after suffering heavily, was withdrawn (Jan 24, 1900).

By Feb. 1 Roberts had matured his plans; on the 3rd he ordered a demonstration against the right of the Boer position at Spytfontein-Magersfontein to cover the withdrawal of French's cavalry from before Colesberg, and the concentration of his army at Modder river, disregarding another set-back in Natal to Buller, who had against his advice made a third attempt to relieve Ladysmith and failed to make good the purchase which he secured across the Tugela (Vaal Krantz).

Roberts's Advance.—Roberts's plan was first to concentrate to his left, taking every measure to induce the Boers to believe that the original scheme of invasion by the centre would now be resumed, and in this purpose he succeeded so well that his field army with the necessary transport for a cross-country march was assembled between the Orange and the Modder without serious mishap. Cronje at the new centre of gravity was not reinforced, all available Boers drawing down towards Colesberg The concentration effected, Cronje still believed that the relief of Kimberley was the object of the gathering behind Modder river, and therefore held on to his Magersfontein kopje The relief of Kimberley was indeed urgent, for dissensions between Rhodes and the military authorities had become acute But to this part of the task only the cavalry division assembled under French was assigned The army itself was to force Cronje into the open and then advance on Bloemfontein from the west. Roberts began his operations on Feb. 11 French started from Ramdam (near Graspan) eastward on that day, intending to make a wide sweep round Cronje's immobile army. Skirmishing with De Wet in the first stages of their ride, the cavalry brigades crossed the Modder at Klip Drift on the 13th Cronje sent only detachments to oppose them, but these detachments were broken through by a sword-in-hand charge of the whole division, and Kimberley was relieved on the 15th The infantry, meeting with great difficulties in its crossing of the Riet at Waterval owing to the country and its own unwieldy transport, followed one and one-half to two days later But Cronje had now realized his danger, and slipped away westward behind French and in front of the leading infantry at Klip Drift. These were deflected by Kitchener westward to follow up the Boer rearguard, and after some delay the remainder of the infantry, at first fronting northwards, swerved westward likewise, while French from Kimberley, with such of his men as he could mount on serviceable horses, headed off Cronje in the northwest. The result, after one premature and costly assault on Cronje's lines had been made by Kitchener, was the surrender of 4,000 Boers at Paardeberg (*q v.*) with their leader on Feb. 29, the anniversary of Majuba. At the same moment came in news at last of the relief of Ladysmith.

Relief of Ladysmith.—It was part of Roberts's purpose to relieve the pressure in Natal by his own operations Buller began his fourth advance on Feb 14, and though this was checked the foothold gained was not abandoned, and a fifth and last attempt (Pieter's Hill [*q v*]) was successful Ladysmith (*q v*) was relieved on Feb 28 It had fared worst of all the beleaguered garrisons, and its 22,000 inhabitants were almost at their last gasp when relief came The casualties from shell-fire had been few, but those from sickness were very heavy. Buller's operations, too, had cost at Colenso, 1,100 men, at Spion Kop 1,700, at Vaalkrantz 400, and now in the last long-drawn effort 1,600 more—over 5,000 in all. But the tide of war had changed The Natal invaders fell back to the mountains which enclose the north of the colony; Oliver and Schoeman retired from Cape Colony; and the presidents of the republics hinted at *status quo* before the war These proposals were rejected by Lord Salisbury.

Capture of Bloemfontein.—The surrender of Cronje and the relief of Ladysmith for the time being paralysed the Boer resistance. Two half-hearted attempts were made early in March, at Poplar Grove and Driefontein, to stem Roberts's advance upon Bloemfontein, President Kruger himself arriving on the scene to give confidence to his burghers But on March 13, 1900, Roberts's army marched into the Free State capital, this in spite of the fact that much transport collected at Ramdam had been cut off by De Wet

It was only on March 29 that the new railway communication recommenced to feed the army In the meantime rebellion had broken out in the Prieska district of Cape Colony, but was promptly quelled by Kitchener. The enforced halt at Bloemfontein was unfortunate; it not only resulted in a bad outbreak of enteric, but it gave the Boers time to recuperate, and by the beginning of April they again took the initiative The death of their commandant-general, Piet Joubert, on March 28, seemed to mark a change in the fortunes of the Republican army. Christian De Wet, who had first come into prominence as the captor of Roberts's convoy at Waterval, and was now operating east and south-west of Bloemfontein in order to counteract the influence of Roberts's numerous flying columns which rode hither and thither offering peace to the burgher, added to his laurels by ambushing Broadwood's mounted brigade and horse artillery at Sannah's Post, just outside Bloemfontein, on March 31 Four days later he reduced a detachment at Reddersburg, and then went south and invested a mixed force at Wepener, which was relieved after ten days by Gen. Hunter's Ladysmith division

Relief of Mafeking.—On May 11 Roberts and his army moved northwards upon the Transvaal capital, Pretoria. A flying column on May 17 relieved Mafeking, where Col Baden-Powell had throughout shown an unconventional gaiety The same day the Natal Field Force under Buller moved up into the Biggarsberg and occupied Dundee. On May 12 Roberts entered Kroonstad, and on May 31, occupied Johannesburg, the Orange Free State having been annexed three days earlier. On May 30 President Kruger had fled with the State archives to Waterval Boven on the Komati Poort line The gold mines were now securely in the possession of the British, and on June 5 Roberts occupied Pretoria practically without resistance

Diamond Hill.—The army of occupation had still to face two years of almost unprecedented partisan warfare. On June 8 Buller, who had made a long halt after the relief of Ladysmith and reorganized his army and its line of communication, forced his way over Alleman's Nek, and on the following day occupied Laing's Nek, the Natal gate to the Transvaal, while Roberts fought a widespread battle against Botha, De la Rey and Kemp at Diamond Hill, 20m east of Pretoria. The object of this action was to push back the Boers from the neighbourhood of Pretoria, but no sooner was this done than the north-western Transvaal became active, in spite of Hunter's and Baden-Powell's advance from Mafeking through this district. As the British line of operations now extended eastward from Pretoria, the advance of these Boers to the Magaliesberg threatened their rearward communications, and as Buller had moved far more slowly than the main army there was not as yet an alternative line through Natal Most serious of all was the pressure between Bloemfontein and the Vaal, where the Free Staters, under De Wet and other commanders, had initiated the guerrilla war as soon as Botha and the Transvaalers retired over the Vaal and ceased to defend them by regular operations Large forces had been left behind during the advance on Johannesburg for the protection of the railway and the conquered territory, and these had now to be reinforced. Hunter and Rundle successfully herded Prinsloo with 4,000 Free Staters into the Brandwater Basin (July 29)—a very satisfactory result, but one seriously marred by the escape of De Wet, who soon afterwards raided the Western Transvaal and again escaped between converging pursuers under Kitchener, Methuen, Smith-Dorrien, Ian Hamilton and Baden-Powell.

Flight of Kruger.—Before this Roberts had initiated a movement from Pretoria to sweep down to Komati Poort on the Portuguese frontier, in which Buller, advancing across country from the south, was to co-operate On Sept 25 Komati Poort was

occupied by Roberts's troops. From October the military operations were confined to attempts to reduce guerrilla commandos which had taken the field. Kruger, deserting his countrymen, left for Europe in a Dutch man-of-war, and Buller sailed home. The Boer leaders definitely decided upon a guerrilla policy, deliberately dispersed their field army, and then swelled and multiplied the innumerable local commandos. On Oct. 25 the ceremony of annexing the Transvaal was performed at Pretoria.

Kitchener Takes Command.—The prevailing opinion was that the war was over, and Roberts left South Africa, handing over the command to Lord Kitchener. Then followed a long period of groping for a means to cope with the development of guerrilla tactics, which for the next six months were at their zenith. The railway communications were constantly damaged, isolated posts and convoys captured, and the raiders always seemed able to avoid contact with the columns sent in pursuit. De Wet, after escaping from Brandwater Basin, was hunted north-westward, and crossed into the Transvaal, where, joining the local guerrilla bands, he surrounded an infantry brigade at Fredrikstad. But, unable to reduce it, and threatened on all sides, he turned back. On Nov. 6 he was severely handled and his guns and wagons captured at Bothaville. But this misadventure only stimulated him. His emissaries roused the Free Staters west of Bloemfontein, and disaffection broke out in Cape Colony to an alarming degree, while, as forerunners of the promised invasion, scattered bodies of Free Staters crossed the Orange river to swell the rebellion. From Bothaville De Wet made for Thaba Nchu, where the Bloemfontein garrison held a cordon of posts. He passed through this and on to Bethulie, capturing Dewetsdorp and 500 men *en route*. Pursued closely and finding the rivers in flood De Wet hid some of his men under Kritzinger near the Orange and himself doubled back, traversing again the line of posts east of Bloemfontein. Kritzinger, Hertzog and bodies of Cape rebels raided Cape Colony as soon as they were able to cross the Orange, and Hertzog penetrated so far that he exchanged shots on the Atlantic coast with a British warship. All that the British forces could do was to localize the raids and to prevent the spread of rebellion. Botha meanwhile held his own in the northern Transvaal, attacked the railway posts on the Middelburg railway and captured Helvetia. De la Rey operated successfully and scathelessly in the western Transvaal, in concert with Beyers. Kitchener called for more men, and on Dec. 22 the War Office announced that 30,000 more mounted men would be despatched to the seat of war.

Concentration Policy.—With the opening of 1901 Kitchener tried new schemes. He withdrew all his detached garrisons except in the most important centres, and set himself to make his railway communications secure. He determined to make the area of operations a waste, and instituted the concentration camps, into which he intended to bring the whole of the noncombatant inhabitants of the two republics.

Although there were no great disasters, the new policy was not prolific in success. The enemy invariably dispersed before superior forces, and the removal of the women and children from the farms did not have the effect of disheartening the burghers as had been anticipated—it rather mended their vitality by relieving them of responsibility for their families' welfare.

On Feb. 10 De Wet, with five guns and 3,000 men, carried out his promised invasion of Cape Colony. Passing the Bloemfontein-Thaba Nchu cordon a third time, he crossed the Orange to join Hertzog and rouse the Cape Dutch. But this invasion failed. By judicious use of the railway Kitchener concentrated sufficient troops in the Colony to cope with the attempt, and, after being hunted for 18 days, De Wet escaped into the Orange River Colony with the loss of all his guns, munitions and half his force. In the northern Transvaal a force under Sir Bindon Blood cleared the country, but could not prevent Viljoen from escaping eastward to join Botha. Botha's activity in the south-east caused Kitchener to despatch thither a large force under French. This swept the country up to the Swaziland border, but Botha escaped. On March 3, after various raids, De la Rey, the lion of the western Transvaal, essayed an attack upon Lichtenburg, in which he was heavily repulsed. Signs of weakness were now apparent, and as a result Louis Botha, acting with the authority of Schalk Burger, the representative of President Kruger, opened negotiations with Kitchener. A meeting took place at Middelburg, Transvaal, on Feb. 28. These negotiations, however, broke down mainly over the treatment to be awarded to Cape rebels.

Blockhouse Policy.—Kitchener now resolved upon chains of blockhouses like those protecting the railways. In April Plumer occupied Pietersburg, the last remaining seat of government open to the enemy. In July, Botha applied for permission to communicate with Kruger. This was allowed, but, Kruger advised a continuance of the struggle. In the meantime, the concentration camps were becoming filled to overflowing, and a steady stream of captures were reducing the Boer resistance.

In August a proclamation was promulgated formally threatening the Boer leaders who did not surrender with permanent banishment from South Africa, but this proclamation had very little effect. Desultory fighting continued till the close of the year. Affairs again took an unsatisfactory turn in Cape Colony, and on Oct. 8 the whole colony was placed under martial law. The British began a succession of night marches and raids which practically blotted out the resistance in the eastern Transvaal. The year closed on a low note, however, as De Wet on Christmas Eve captured a large force of Yeomanry at Tweefontein.

The "Drives."—In 1902 the blockhouse system was finished. But the enemy still had about 25,000 men in the field. The mobile columns, of which there were over 60 in the field, could be pushed out along whatever blockhouse line they touched. In January, Viljoen was captured in the Leydenburg district. Early in February Lord Kitchener commenced his first drive, and it was so successful that it was evident that the key to the situation had been found. First the country east of the line Bloemfontein-Vereeniging was swept four times over, then the method was employed in the Transvaal, east and west, and finally against the Cape rebels. There were a few reverses, of which De la Rey's successful rush upon Paris's column and the capture of Lord Methuen were the most important, but when some initial mistakes in the composition of the driving lines, which robbed the earlier drives of part of their effect, were made good, the system worked like a machine. The Boers were at last convinced of the futility of any attempt to prolong the struggle, and on March 23 the representatives of the Boer Governments came into Pretoria. Six weeks were spent in negotiation, and then a meeting of delegates, under the presidency of Gen. Kemp, was held at Vereeniging.

Peace of Vereeniging.—As a result of this conference articles of peace were signed at Pretoria on May 31; their essential points were: (1) Surrender of all burghers in the field, with all arms and munitions of war; (2) all burghers duly declaring themselves subjects of King Edward VII. to be repatriated; (3) no burghers who should surrender to be deprived of either their liberty or property; (4) no proceedings to be taken against burghers for any legitimate acts of war during the period of hostilities; (5) the Dutch language to be taught in public schools on the request of parents, and to be allowed in courts of law; (6) sporting rifles to be allowed upon the taking out of licences; (7) the military administration to be superseded by civil administration as soon as possible, the civil administration to lead up to self-government; (8) the question of the native franchise not to be considered until after the introduction of self-government; (9) landed property not to be subjected to any special tax to defray the cost of the war; (10) a commission to be formed to facilitate the repatriation of the burghers, a grant of £3,000,000 being given as compensation for the destruction of farms.

In the whole war the British lost 5,774 killed and 22,829 wounded, while the Boers lost about 4,000 killed. The number of Boer prisoners in the hands of the British at the end of the war was about 40,000. (L. J.; C. F. A.; X.)

SOUTH AMBOY, a city of New Jersey, U.S.A., on the Raritan river, opposite Perth Amboy, with which it is connected by the fine Victory bridge (opened 1926). Pop. (1920) 7,897 (83% native white). South Amboy has terra-cotta works and was laid out in 1835, becoming a city in 1908.

SOUTH AMERICA, the southern of the two American continents of the Western Hemisphere, situated between 34° and 82° W. long., and 13° N. and 55° S. lat. It is roughly triangular in shape and in the north-west is joined to the continent of North America (*q v.*) by the Isthmus of Panama South America is the 4th largest of the continents having an approximate area of 7,570,000 sq m, or about 14% of the land surface of the globe. Its estimated population in 1928 was 74,500,000, or 9·8 per sq.m. South America lies much farther east in the Atlantic Ocean than North America, the meridional line of New York city cutting it so as to leave 95% of the southern continent lying closer to the Old World *See* also AMERICA

PHYSIOGRAPHY

The Coasts.—The South American continent rises abruptly from the ocean floor along nearly all of its coast but the steepness of the continental margin is more marked on the western side than on the eastern. On the west coast between 5° S. lat. and 35° S. lat. the continental shelf is extremely narrow and is bordered by abysmal faults (the 3,000-fathom line lies less than 60 m from the coast-line at Iquique) In this section, and in fact throughout their whole length north of Valparaiso, the Andes, in spite of their great height above the sea, are only the upper portions of mountains whose bases are thousands of feet below the surface of the Pacific ocean. South of Valparaiso the continental shelf broadens, but it is nowhere of great width and at the entrance to the Strait of Magellan again narrows so that the 1,500 fathom line is within 150 m of the coast-line In general the Pacific coast follows the direction of the Andes. The whole west coast north of the Patagonian archipelago is but little articulated and is completely lacking in good natural harbours The harbours of Guayaquil and Buenaventura would be exceptions to this rule if it were not that the rivers which empty into them carry so much silt that only constant dredging or carefully engineered dykes to direct the flow and deposit of the silt would make them possible for steamers of deep draught.

From 41° S lat to Cape Horn the coastal zone is a broad chain of islands which were probably formed by recent subsidence of a mountainous strip and the consequent invasion of its valleys by the sea. The islands, some of which are very large, are only the higher portions of these mountains that have remained above the sea, while Smyth channel, the Strait of Magellan, and other large channels and sounds are submerged valleys. The channels, which separate the islands near the mainland and extend back like fiords into the mainland cordilleras, appear to have been greatly over-deepened by the action of the old glaciers Even to-day great glaciers flow down from the inland ice-fields of the cordilleras to the heads of many of these fiords and, along the Beagle Channel, to the coastline of the channel itself Many of the larger islands are steep, barren mountain masses which rise to altitudes of 4,000 ft. and in some cases bear glaciers (mostly of the hanging type, but in some cases long valley glaciers that reach to the sea) on their protected north and north-east slopes

North of 41° S lat the coast belt between the Andes and the ocean averages about 40 m in width. Its character varies greatly. In southern and central Chile it is occupied by high coast ranges From 30° S. lat to the mouth of the Guayas river it is a sandy arid belt broken by a discontinuous line of coast ranges Across this arid belt flow streams from the Andes which water narrow, fertile valleys. Few of these streams, however, are perennial; many never reach the sea, and others reach it only in time of flood. North of the mouth of the Guayas river the coastal belt is covered with tropical vegetation.

The east coast is in strong contrast with the west. Between Cape San Roque and São Paulo the coast to some extent follows the orientation of the eastern border of the Brazilian plateau On this part of the coast are some of the most beautiful harbours in the world, notably those of Rio de Janeiro, Santos, and Victoria. These harbours are submerged coastal valleys but the subsidence which produced them was limited in extent and probably did not affect the whole east coast In fact in north-eastern Brazil uplift movements have added to the coast a belt of marine deposits. The estuary of the Rio de La Plata is the most marked indentation of the whole South American coast. It is the outlet for the combined waters of the Uruguay and Paraguay river systems South of the La Plata in the Patagonian region many great transverse valleys open to the Atlantic but the recession of the glaciers of the Patagonian Andes, which during the Ice Age were an abundant source of supply, has greatly diminished the streams in many of these valleys. Others, since the recession of the glaciers and the re-opening of old drainage channels through the Andes to the Pacific, are completely dry

The east coast of South America has few islands and these, except Trinidad, off the coast of Venezuela, and the islands at the mouth of the Amazon, are mostly small. Trinidad (area 1,755 sq m) is separated from the continent by the Gulf of Paria but along its northern edge is a range of mountains averaging about 3,000 ft high which is geologically a continuation of the Cumana range of Venezuela. On the south side of this island is the famous asphalt lake—the largest known deposit of its kind. West and north of Trinidad and lying farther off the coast are several small islands of historical interest and considerable commercial importance. Tobago, Margarita, Blanquilla, and the Curaçāo group The main island of the Fernando de Noronha group of volcanic islands 230 m off Cape São Roque has an area of only 12 sq m. Although separated from the mainland by a channel 13,000 ft. deep, it really stands upon the submerged corner of the continent. The Falkland islands in lat. 51° S. also stand upon the submerged edge of the continent. Their fauna and flora indicate that they were once a part of the mainland from which they are now separated by shallow water. On the west coast north of the Patagonian archipelagos are the Juan Fernandez islands west of Valparaiso, the famous guano islands close to the mainland of Peru, the Galapagos islands on the equator, and the islands of the delta of the Guayas river near Guayaquil.

Land Relief.—The continent of South America is divided, from west to east, into three longitudinal zones—the cordilleras of the Andes, the lowland belt, and the plateaux of Guiana and Brazil—the last being interrupted at 35° S lat by the narrowing of the continent and the opening of the lowland belt to the Atlantic coast

The Andes, north of their Patagonian section, have been, until recently, described as a series of more or less parallel but distinct ranges It is now known that, except in the two widest sections (the Central Andes of Bolivia, where they consist of two ranges bordering the high *altiplano,* and the Andes of Colombia, where they finger out into three distinct ranges), they form a broad plateau, carved far over toward its western border by tributaries of the great river systems of the Atlantic slope and surmounted by narrow ridges and isolated mountains (many of them volcanoes of various ages) which include some of the highest peaks in the world (For further details *see* article on the ANDES)

The South America lowlands, so-called, include the *llanos* of the Orinoco, the Amazon plains, the *Chaco,* and the *Pampa,* and form a more or less continuous belt reaching from the mouth of the Orinoco to the northern border of Patagonia north of the Rio Negro Patagonia, however, may also be properly included in the lowland belt. There is no sharp line of division between it and the *Pampa;* much of its surface has a steppe-like character, and its soil-cover is alluvial like that of the rest of the lowland belt This alluvial cover, throughout the lowland belt, is mainly of Andean origin supplemented locally by elements derived from isolated mountain masses that here and there break the general level. In the regions of heavy rainfall the alluvial soils are almost entirely distributed by water. In the *Chaco,* where the rainfall is distinctly seasonal in character and the network of streams from the Andes does not reach far into the lowlands, the transportation of alluvial deposits is assisted by the winds during the dry season On the *Pampa* it is almost entirely transported by the winds The cover of rounded pebbles characteristic of large sections of Patagonia is believed to be of glacial origin distributed from the fronts of the old glaciers by water before the streams had been confined to definite beds and since that time by action of the winds Throughout the lowland belt are evidences of im-

perfect stability, of movements of uplift and subsidence that have given rise to new local cycles of erosion and alluviation.

Geologists now recognize a close relationship between the highlands of Guiana and those of eastern Brazil. Both are composed of a shield of ancient crystalline granites and gneisses and of old folded schists and quartzites on platforms of sandstone, and belong to an old continental mass recently raised by vertical movements to its present elevation. At the edge of the Brazilian plateau falls still occur even on the largest rivers, some of which, like the São Francisco, flow on the surface of the plateau, while others, as in the southern part of Goyaz and Minas Geraes, have eroded deep gorges there. The interior is occupied by high monotonous surfaces at various levels and in a more or less perfect state of peneplanation. In the Guianas, however, and in the Serra do Mar of Brazil the mountains have the convex-dome shape characteristic of crystalline mountains under the action of intense tropical rainfall. The mountains of the Serra do Mar are extremely picturesque. At many points they rise directly from the seashore to an elevation of 2,000 ft., forming in places bare granite walls. In other places they are covered with luxuriant tropical vegetation. Their highest point (7,323 ft.) is in the Serra dos Orgãos near Rio de Janeiro.

Rivers and Lakes.—The most important river systems of South America—the Amazon, Orinoco, and the Paraná-La Plata system—have the greater part of their drainage basins in the lowland belt. The chief headwater tributaries of the Amazon and the Orinoco have their sources on the Andean plateau where they have cut deep valleys. The principal sources of the Paraná-La Plata system are in the Brazilian plateau, although the Pilcomayo and Bermejo (right bank tributaries of the Paraguay) rise in the Andes of southern Bolivia and northern Argentina. These three river systems together drain an area of about 3,700,000 sq.m. During the rainy season all of them overflow their banks and flood large sections of the central lowland belt. The Amazon is the largest river in the world. The main stream is navigable for ocean steamers as far as Iquitos, while many of its tributaries are navigable for steam launches almost to the foot of the Andes. In the time of high water the main stream of the Orinoco is navigable for 1,000 m. or more. Other important rivers are the Magdalena in Colombia, the Essequibo in British Guiana, and the São Francisco in Brazil. The Magdalena is navigable, in two sections separated by the rapids at Honda, for river steamers as far as Girardot, the river port of Bogotá. The São Francisco which rises in the highlands of Minas Geraes is navigable nearly to the falls of Paulo Affonso, 140 m. from its mouth, and also above the falls.

Most of the lakes of South America are mountain lakes in the Andes or along its base. Of the Andean lakes, Titicaca and Junín are the largest. (*See* ANDES.) The glacial lakes along the eastern base of the Andes in southern Argentine and those of the Llanquihue district of southern Chile are described in the articles on the Andes, Argentina, Chile, and Patagonia. There are many lakes scattered over the flood plains of the great rivers but these are mostly phases of river development. Along the east coast there are occasional lakes, like the Lagoa dos Patos of southern Brazil, of brackish water, produced by depression of the coast and the closing of the mouths of estuaries formed thereby or by barrier beaches thrown up by the sea. Lake Maracaibo is a large narrow-necked bay like that of Rio de Janeiro rather than a true lake.

GEOLOGY

The most extensive old land areas (Pre-Cambrian) of South America are found in the plateaux of Guiana and Brazil where the ancient crystalline granites and gneisses have been laid bare over large areas. The *Brasilides,* so-called, are a series of Pre-Cambrian and Pre-Devonian folds of which traces are found on the western border of the Brazilian plateau and as far south as the Sierras in the Argentine provinces of Cordoba and La Rioia. These old land areas formed the larger units in a chain of islands of which the old rocks of the Falkland islands are a part. On their shores were laid down the sedimentary beds of the Cambrian seas. At the close of the Cambrian period these Pre-Cambrian islands with their Cambrian sediments were uplifted and many of them united to form continental masses of considerable extent. During the Silurian period, however, seas still covered a large area including the present basin of the Paraguay river and a large part of the present basin of the São Francisco and extending northward between the axis of the Andes and the Matto Grosso highlands and eastward by way of the region now occupied by the lower Amazon valley.

During the Devonian period further uplift and the consequent disappearance of the Silurian seas from the basin of the São Francisco increased the area of the continental mass; but in early Carboniferous times the sea still covered a narrow strip through the lower part of the Amazon valley and part of what is now the Andes south of the Equator. During the Permian the basin of the Paraguay and the south-east coast of Brazil were covered with lagoons and swamps in which here and there coal beds were laid down. Continental Permian deposits have been found at a number of places in the southern part of the Brazilian plateau, in northern Argentine, and in the Falkland islands. Analogies between Permian fauna and flora of South America and South Africa are accepted as evidence of a Permian continental mass, known as *Gondwana,* connecting South America with South Africa and India, the western limits of which are formed by the Argentine pre-cordillera between San Juan and Jachal where the Permian layers are strongly folded. These folded Permian layers are continued south-eastward by the sierras of the Argentine province of Buenos Aires and are known to geologists as *Gondwanides.* South of them, between the Negro and Chubut rivers, is the Patagonian massif, which consists, like the *Brasilides,* of very old rocks and may have been connected with an ancient Antarctic continent. Against this massif and between it and the Andes, and antedating the latter, is a series of Cretaceous folds known as *Patagonides.* At the close of the Devonian there was widespread volcanic activity that covered with lavas large areas in what is now Paraguay and Brazil.

The importance of Jurassic and Cretaceous marine deposits in the Andes is evidence that, during the Mesozoic period, the region now occupied by the Andes was a great geosyncline occupied by the sea between two continental masses, one of which has since subsided to form the Pacific ocean. This geosyncline connected at the north end with a sea that reached from the region of the present West Indies to the present Mediterranean and persisted through the Mesozoic and into the early part of the Tertiary. The South America-South Africa land mass (*Gondwana*) continued from the Carboniferous to the Cretaceous and may have persisted into the Tertiary. There is no evidence on the present coast of Brazil of invasion by the sea between the Devonian and the Cretaceous, while the first invasion of the east coast of Patagonia and, consequently, the formation of the South Atlantic ocean dates from the Upper Cretaceous. The folding of the Andes also began in the Upper Cretaceous and continued into the Tertiary, although how far into the Tertiary is not known.

Great changes took place in the Tertiary period. The continent rose considerably higher than its present elevation and the continental land mass was, consequently, much larger than at present, including such coastal islands as the Abrolhos islands on the east coast of Brazil and the Falklands. It is possible, also, that, during this period, South America had land connection with New Zealand and Australia by way of the Antarctic continent or through the south Pacific ocean. The formation of the Isthmus of Panama with the resulting migration of North American faunal species to South America also dates from the Tertiary period; but its formation could not have taken place until the Pliocene, since the analogies between the marine fauna beds of Navidad (Chile), which date to the end of the Miocene, and European fauna of the same date can only be explained by the existence of free communication between Europe and the west coast of South America by way of the Tertiary Mediterranean up to the end of the Miocene. The elevation of the Andes during the Tertiary period was due only in part to the elevation of the continent as a whole. It was in large part assisted by the folding of the rocks and the outpouring of lavas and the accumulation of other volcanic mate-

rials in the neighbourhood of the vents. Nor was this volcanic activity confined to the Andean region. It extended into Venezuela and the islands along the north coast, the Patagonian plains, the highlands of the Paraná basin, and as far east as the islands of Fernando de Noronha. Toward the end of the Tertiary subsidence again occurred and the sea entered the Amazon, Orinoco, Cauca, and Magdalena valleys and the Maracaibo basin, and again made an island or groups of islands of the Guiana highlands

In recent times, volcanic activity has greatly diminished over the continent and has ceased entirely in its eastern and north-eastern section Throughout the southern part of the continent there is evidence of several periods of glacial development and recession during the Ice Age Ice covered the whole of the Patagonian plateau as well as the western side of the Andes but the continental glaciation did not extend as far north on the east side of the Andes as on the west. Throughout the Andean zone there is evidence that the present glaciers are only remnants of much larger glaciers There were no glaciers in the eastern or Brazilian section of the continent

CLIMATE

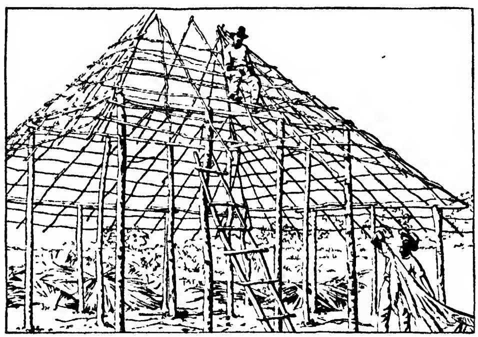
South America is the only one of the southern continents which extends far into the temperate latitudes; but, unlike the land masses of the northern hemisphere, it tapers toward the pole and, therefore, does not experience the extremes of temperature of the northern continents The winters in the temperate latitudes are much warmer and the summers cooler than in North America or Asia At no time of the year are there freezing temperatures at sea-level The continent is broadest in the equatorial section and has the widest expanse of truly tropical weather of any of the continents, but, because of the width of the zone covered by the Andes, it has also the greatest area of temperate and sub-Arctic climate in tropical latitudes. Off the west coast from Cape Horn to the Equator the isotherms bend sharply toward the north. North of 40° S lat. this is due to the cooling effect of the Humboldt Current The east coast as far as the La Plata estuary is washed by the warm south equatorial current which the projection of the continent at Cape San Roque divides into two branches. There it meets the cool waters of the Falkland Current flowing north from Cape Horn

Except in the south the winds blow parallel to the Andes on the west coast They bring heavy rainfall to Ecuador and Colombia. South of this section, however, to 30° S. lat, the western side of the Andes and the coast are very dry on account of the Humboldt Current and the colder upwelling waters between it and the coast, and what little rain does fall there falls in the coolest months. South of 35° S lat. there is much rain all the year but the maximum is in autumn and winter. This is the region of the Roaring Forties which in summer extend as far north as central Chile so that the Santiago region has mild rainy winters and rainless summers. In general the Andes offer a barrier to surface air circulation from both sides; but, south of 40° S lat. they are relatively low, and the west winds are able to cross them, their ascent bringing heavy rainfall to the Chilean side while their descent causes the sparse rainfall of Patagonia On the north coast of Colombia and the coasts of Venezuela and the Guianas the north-east trades blow all the year, strongest and steadiest in January and weakest during July when the rainy season occurs. The Equatorial zone has a double rainfall maximum from the north coast to about 10° S. lat.; but, except on the Equator, there is really one long rainy season with two especially heavy maxima In all seasons the east coast, from Cape San Roque to the Tropic of Capricorn, has easterly winds varying from south-east in July to east and north-east in January Between the tropic and the La Plata estuary the coast is on the west side of the south Atlantic anticyclone all the year and has, therefore, warm rainy winds.

SETTLEMENT

Discovery.—The continent of South America was first visited by Europeans in 1498 when Columbus, on his third voyage, touched near the mouth of the Orinoco. Others soon followed and by 1509 the east coast had been followed as far as the Rio de La Plata. In 1513 Balboa discovered the Pacific ocean at the Isthmus of Panama; in 1520 Magellan navigated the strait that bears his name; in 1527 Pizarro landed on the coast of Peru at Tumbez and, in the same year, Cabot ascended the La Plata and Paraná rivers as far as the mouth of the Bermejo, in 1533 Cartagena was founded and the native town of Quito peacefully occupied; in 1535 Pizarro founded Lima and, in the same year Almagro invaded Chile and Mendoza established a settlement at Buenos Aires; in 1537 Jiménez de Quesada made his way from Santa Marta up the Magdalena river to Bogotá, the capital of the Chibchas, and in 1541 Valdivia founded Santiago de Chile and Orellana travelled from eastern Ecuador to the Atlantic by the Napo and Amazon rivers It is claimed that the bay of Rio de Janeiro was discovered by the Portuguese in 1502 Affonso de Souza visited it in 1531 but went on to São Vicente near Santos to establish his colony The first settlement on the bay was made some years later by French Huguenots

Aboriginal Inhabitants.—At the time of the discovery of South America the aboriginal inhabitants differed greatly among themselves in customs, language and state of civilization Those of the temperate regions of the Andes had reached a high state of culture Wherever the Europeans have invaded in any considerable numbers the aborigines have been profoundly affected. The importation of slaves from Africa has, likewise, had an important effect on the natives of the coastal regions of Brazil and the countries of the north coast. Indians of pure blood still, however, form a large portion of the population, while those of mixed white and Indian blood constitute its chief element except in Argentina, Uruguay and southern Brazil In Brazil and the countries of the north coast there has been, also, considerable intermixing of Indians, negroes and whites. In the interior, where the whites have penetrated but little, the aborigines are still in very much their original savage state In some localities, as on the Argentine *pampa* and in Uruguay, where there has been much recent colonization from Europe, the Indians have practically disappeared In the Andean countries, where they had reached their highest state of culture at the time of the discovery, they still form the major part of the population and the native Quechua and Aymará tongues are still widely spoken The countries having the largest Indian population at present are Bolivia, with an estimated 60–70% of Indians and the remainder mixed Indian and white; Ecuador, with about 50% Indians and 45% mixed, Peru with a small



NATIVES IN RURAL VENEZUELA BUILDING A HOUSE

white population and the remainder Indian and mixed, together with a considerable number of negroes, Japanese and Chinese among the poorer classes in the cities; Paraguay, with a population mainly Indian; Colombia, with about 15% pure Indians and the remainder chiefly of mixed blood; and Venezuela, with few pure whites, a large majority of mixed blood, and a considerable number of negroes.

Settlement and Industrial Development.—Early colonization began and developed for a long period on a completely different basis in South America than in North America Colonists

in North America were seeking new homes and, therefore, settled in regions which duplicated as closely as possible the climatic and agricultural conditions that they had known in Europe. The early colonists went to South America, on the contrary, to exploit such natural resources as Europe lacked. Gold and silver were the first attractions, and the Andean regions, where the mining of these metals was already in an advanced state of development by the natives, were the centres of the first intensive invasion. The centres of mineral exploitation in the Andes were soon widespread. At an early date gold was being washed in Darien, the Ecuadorean Oriente, the valleys of the Cordillera de Carabaya in Peru, and the Araucanian section of Chile. The mining of silver also attracted large numbers. The silver mines of Potosí and Cerro de Pasco were particularly famous, those at Potosí alone being estimated as having yielded in all over a billion and a half dollars' worth of silver. In the eastern part of the continent the exploitation of mineral deposits began much later than in the Andes. Gold was discovered on the Brazilian plateau in 1693, and, in a few years, Minas Geraes, as the gold-mining region was called, came to be the chief gold-producing region of the world. The mines there reached their greatest productiveness between 1752 and 1761, when the annual yield was worth about six million dollars. The actual work of mining in the Andes was done mainly by native labour, in Brazil by native labour and imported negroes.

Mining still remains the chief industry of Chile, Bolivia and Peru; but copper has taken the place of gold and silver in Peru, tin and copper in Bolivia, and nitrates and copper in Chile. Nitrates rank first in value among the mineral products and copper second. Considerable gold and silver are still produced, largely in connection with copper mining. The chief mineral product of Colombia is still gold and Colombia is now the leading gold-producing country of South America; but her annual thirty-five million dollar coffee crop is seven times as valuable as her annual production of gold. Colombia leads the world in the production of platinum but the annual value of her platinum production is less than that of her bananas. Brazil, which, from the first discovery of diamonds in the gold districts about 1729 to the discovery of the South African fields, was the leading diamond producing country of the world, now probably produces less than one million dollars' worth annually, while her coffee crop in normal years is valued at upwards of two hundred million dollars. In fact the whole annual South American production of precious metals and precious stones probably does not exceed twenty-five million dollars, or less than that of a single copper mine at Chuquicamata, Chile. In the Maracaibo basin and the lower Magdalena valley, on the Peruvian coast at Talara, and in the Comodoro Rivadavia region of Argentina, the production of petroleum is rapidly increasing.

Agriculture in the hands of the Spanish colonists, or, as was more commonly the case, agriculture superintended by the Spanish but carried on by native labour on Spanish-owned estates seized from the natives, to which the Indians were bound by a system derived from the communal organization of the Incas, developed first around the mining centres which supplied their market. In fact the whole life of the Andean region came to be, and still is, centred in the mining industry. Farmers and traders found in the mining centres their markets not only for foodstuffs but for pack animals as well. The Andean towns and cities were, and are today, centres of service and supply for the mining districts. In addition, the transportation of minerals from the mines and supplies to them necessitated that a considerable portion of the population should be engaged in packing over the difficult trails not only to and from the towns of the plateau but to the coast as well. Next in importance to the mines in attracting colonists to South America were the tropical agricultural products. Sugar cane was for long the principal crop, followed later by cotton, indigo, cacao and coffee. The tropical crop colonies developed first in the Brazilian states of Bahia, Pernambuco and Maranhão, and spread later to the Guianas and northern Venezuela and Colombia. To-day only a small part of the world's supply of cotton and sugar comes from South America, mainly from Brazil. Argentina and Peru. Brazil, Ecuador and Venezuela still produce about one-third of the world's crop of cacao. Coffee now not only is the leading tropical export of South America but the chief agricultural export of the whole continent, the greater part coming from Brazil but an important amount from Colombia and Venezuela. The export second in importance now is wheat, mainly from Argentina which is also the world's leading producer and exporter of flaxseed.

The grazing industry dates from the early days of colonization.

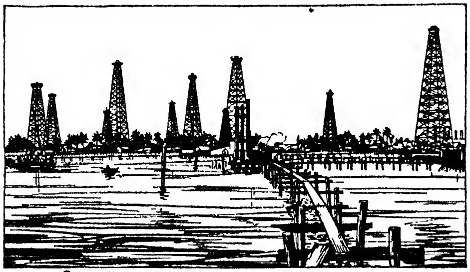
A SNAKE FARM NEAR SAO PAULO, BRAZIL

The three chief grazing districts of colonial times were the northern Brazil district which supplied Bahia and Pernambuco, the south central Brazil district which supplied Minas Geraes and Rio de Janeiro, and the Argentine *pampa*, which supplied the mining centres of Bolivia and Peru. Exports from the cattle-growing regions consisted until fairly recently almost entirely of hides, as is still the case with Chile, Colombia, Venezuela, the Andean countries, and the interior of Brazil. Only Argentina and Uruguay are even to-day large exporters of beef, although southern Brazil ships a considerable amount. The first meat exported from Argentina was jerked beef and even in 1876, it consisted chiefly of mutton. The shipping of frozen beef began some time later but it was not until 1901 that chilled beef was shipped in quantities. Now Argentina exports more beef than any other country in the world. Sheep are still numerous in Uruguay and on the *pampa*, but they have been greatly decreased by the spread of cattle-raising and the cultivation of the land for cereals and alfalfa. In Patagonia and in Tierra del Fuego the sheep industry has had a remarkable development. In the exportation of wool Argentina, with three to four hundred million pounds of wool shipped annually, is second only to Australia.

The exploitation of the forests in South America, as elsewhere, has had little to do with the establishment of permanent colonies, although it has at times seriously depleted those already established. In the 18th century the sugar-mills of Maranhão were deserted for the exploitation of cacao found in the neighbouring forests. In the 19th century men left the cacao plantations to search for rubber. In general only the most precious forest products have been exploited for exportation, such as logwood, rosewood, woods rich in tannin, quebracho, rubber and the vegetable ivory nut. In the east slope forests of the Andes of Bolivia, Peru and Ecuador, the collecting of cinchona bark, from which quinine is extracted, was an important industry from the middle of the 18th to the latter part of the 19th century and was at one time one of the chief resources of Bolivia. The introduction of the tree into Java, Ceylon and India has now, however, completely destroyed the industry in South America. The collecting of maté (Paraguayan tea) is still an important industry in Paraguay. Some Paraná pine is cut in Brazil for exportation to Uruguay and Argentina and saw-mills on the Strait of Magellan are engaged in manufacturing lumber from the forests of the west coast of Patagonia for the Argentine trade; but, in general, the exploitation of forests for lumber is profitable only in the vicinity of important towns. In the early days of the railroads much wood was consumed by locomotives but it is largely, though not entirely, supplanted now by coal and petroleum. Along the routes of the river steamers there is still a large demand for wood for fuel. The main routes for the transportation of lumber and other forest products are the rivers of the Atlantic side of the Andes and river

ports are the chief centres of the industry—Itaquy on the Uruguay (centre of the maté industry), Posadas, Iquitos and Manãos.

One result of the wide dispersion of the early colonies in South America was the development of long transportation routes. The most famous of these was that from the Rio de La Plata settlements to Lima by way of the mining centres of Bolivia and southern Peru. Its function was not only that of the route by which cattle from the *pampa* were driven to the mining centres but also to serve as a link in the line of communication and supply between Spain and the Rio de La Plata settlements since, by decree of the Court of the Indies, direct communication between Europe and the Spanish settlements of the east coast was forbidden. There was also in colonial times much traffic on the large rivers of the Amazon and Paraná systems but these rivers were of little importance in transcontinental traffic because of the difficult ascent of the Andes from the heads of navigation. Everywhere, more or less local, but still, in many cases, long and arduous pack routes were developed between the productive areas, whether mineral or agricultural, and the local markets or the coast ports. In the Andes the mules became the chief beast of burden. On the lowlands east of the Andes where wheeled traffic was possible the ox hitched to great carts was used Even to-day only the Argentine *pampa*, with about 25,000 miles of track, and the coffee region of Brazil, with about 20,000 miles centring at Rio de Janeiro and Santos, have a real network of railways Elsewhere the pack train is still an essential feature in transportation. In the west coast and Andean countries, except in Chile where a longitudinal railway has been built for strategic reasons, the railways are chiefly short lines from the mining centres to the nearest ports The exchange of commodities between the South American countries is limited and is served chiefly by water routes Only two railway routes cross the continent—the transandine route from Buenos Aires to Valparaiso opened in 1909, and the route from Buenos Aires to Mollendo by way of La Paz (all rail except for the Lake Titicaca section), the last link of which was completed in 1926. Motor road mileage is still limited although good progress is being made.



OIL FIELDS OF LA ROSA, TOUCHING LAKE MARACAIBO

The direction of the maritime trade of South America has been greatly affected by the World War and the completion of the Panama Canal Whereas in 1913 the total tonnage of the traffic between South America and Europe was about five times that between South America and the United States, it has now been reduced to about four times as much. Traffic is still much better balanced between the east coast of South America and Europe than between the east coast and the United States, many ships returning to the United States in ballast. The United States now has, however, more than half the traffic with the west coast. The total annual foreign trade of South America is still small (about three thousand million dollars) and half of it is carried on by Argentina alone. Not only do none of the South American countries produce any of the manufactured articles that are involved in world trade, but they do not supply to any appreciable extent manufactured articles for home consumption. There is, as in all pioneer countries, a considerable amount of home manufacturing carried on—weaving, furniture making, and the like—and some manufacturing in the larger cities, but the total of the latter does not equal that of a fair-sized city in the United States. As a result there are few large cities in South America, Buenos Aires with about 2,000,000 people and Rio de Janeiro with about 1,000,000 being the only ones of world importance

Political Divisions and Population.—The original Spanish colonies revolted from Spain toward the end of the first quarter of the 19th century and formed themselves into ten independent republics, the boundaries of which were based on the limits of the original colonial divisions Brazil separated from Portugal as an independent monarchy in 1822, but did not establish herself as a republic until 1889. Only three European colonies remain on the continent—British and French Guiana, and Surinam (Dutch Guiana). Many disputes were involved in the establishing of the international boundaries on account of the vague language of the Royal decrees which established the original colonial divisions and the hazy knowledge of the topography of the continent upon which they were based These have gradually been settled until only three of importance remain—the Peru-Ecuador dispute over the territory between the Amazon and Putumayo rivers, the Bolivia-Paraguay dispute, and the Tacna-Arica dispute

Previous to the separation of the colonies from the mother country, the colonists, except for the negroes introduced into Brazil and the north coast colonies, were almost entirely Spanish and Portuguese. Since that time there has been little emigration from other European countries to the west and north coast countries except to Chile, where there has been a considerable immigration of Germans. In fact there has been little immigration of any kind into the west countries and little into those of the north coast except for the introduction of coolies from India and the East Indies to British and Dutch Guiana, respectively On the east coast, however, there has been a large immigration from Europe. The 1914 census of the Argentine Republic gave a foreign-born population of 929,863 Italians, 93,634 Russians, 82,970 Spaniards, 79,491 French and 26,995 Germans. Brazil had, according to the census of 1920, a foreign-born population of 558,405 Italians, 433,575 Portuguese, 219,142 Spaniards and 52,870 Germans The population of Uruguay is about 25% foreign-born, mostly Italians and Spaniards Six of the South American republics have taken a census in this century—Uruguay (1908), Argentina (1914), Colombia (1918), Brazil, Chile and Venezuela (1920). Of the European colonies the British had a census taken in 1921 and the French in 1926. No census of Surinam has ever been taken Population estimates for 1928 give the following figures. Argentine Republic, 10,500,000, Bolivia, 3,500,000, Brazil, 37,000,000; Chile, 4,000,000; Colombia, 6,500,000; Ecuador. 1,500,000, Paraguay, 800,000, Peru, 5,500,000; Uruguay, 1,700,000; Venezuela, 3,000,000, French Guiana, 48,000; British Guiana, 300,000, and Surinam, 140,000.

ARCHAEOLOGY

No form of script existed in this continent; no system of recorded dates, as among the Maya, and no pictographical historical records, as among the Aztec, are found. Our reconstruction of the early history of the southern continent is based on the application of traditions, collected in the sixteenth century, to the results of the spade; and for large areas tradition is entirely lacking, and archaeological exploration is scanty. All the higher manifestations of culture are confined to the Andean highlands and the Pacific coast, roughly between Quito in Ecuador and northern Chile and Argentina, embracing, therefore, both Peru and Bolivia. But this culture had not penetrated the densely forested eastern slopes of the Andes, where the scattered population lived under extremely primitive conditions. Tradition is abundant in connection with the Inca of Peru, but the rise of the Inca to power only began about A.D. 1100 and tradition has very little to tell concerning the, in certain respects superior, "civilization" which had flowered and faded before Inca times, but which provided the basis of Inca culture. The Inca may thus be regarded as similar to the Aztec of Mexico, whose cultural life was based on Maya inspiration, but Inca rule was founded on ideas and ideals which differed widely from those of the Aztec. Our conception of this earlier period is founded almost entirely on archaeological research in the field, and it is a regrettable fact that so much excavation in South America has been undertaken by treasure-hunters who had no idea of the importance of the proper documentation of specimens. Excavation on scientific lines has only been carried out in limited areas, principally by Uhle, and later by Tello.

History.—The earliest manifestations of advanced culture in South America appear to have arisen more or less simultaneously in three widely separated geographical regions, the centres of which were, respectively: Tiahuanaco (at the southern end of Lake Titicaca in Bolivia, some 13,000 ft. above sea-level); Nasca on the coast in southern Peru; and Truxillo, also on the coast, in northern Peru. The early remains of these areas are known usually as Tiahuanaco, Proto-Nasca, and Proto-Chimu, but though they show certain very definite individual characteristics, there is an underlying similarity, which is most apparent in the case of Tiahuanaco and Proto-Nasca. Sequence-dating seems to suggest that these three centres flourished between the second century B.C. and the second century A.D., and were therefore more or less contemporaneous with the Early Maya of Central America. Archaeological evidence, as far as it is available, seems to indicate that the Tiahuanaco people gradually extended their influence northward throughout the highlands, possibly as far as Ecuador, and eventually dominated the coast as far north as Lima.

These three cultural centres suffered a collapse, and roughly between A.D. 800 and 1100 there was a "dark age" of degeneration which prevailed over the whole of the region. Then followed a "renaissance." On the coast Truxillo reappears as a cultural centre (the Chimu period). Further south the province of Yca revived the old Proto-Nasca art (the Nasca period), and in the highlands, the Inca succeeded to the heritage of the Tiahuanaco folk, and not only repeated but surpassed their predecessors in the development of an "empire" which eventually extended over coast and highland from Quito to the river Maule.

Records and traditions of the coastal population are almost entirely lacking, and the traditional history of events there is derived from Inca sources. Unfortunately the accounts preserved are not in agreement on all points, and it is not easy to reconcile discrepancies. For instance, one of the most important documents relating to Inca civilization is the account of Garcilasso de la Vega, son of a lady of the ruling Inca house by one of the conquerors, who had been brought up in his mother's family, and had exceptional opportunities for collecting the ancient traditions. But his natural sympathies led him to stress the virtues of the Inca regime to the point of exaggeration. On the other hand, the "official" history of Sarmiento was written rather with the idea of showing the Inca in the light of oppressors and the Spaniards as liberators. Between these two extremes lies the puzzling account of Montesinos.

While other accounts of Inca history give a list of twelve or thirteen rulers, Montesinos, who gives about one hundred, had access to the vanished work of Blas Valera, and it is more than probable that Montesinos' list includes both the chiefs of the Inca clan before they rose to power in Cuzco, and the rulers of the previous Tiahuanaco "empire."

In general terms, the history of the rise of the Inca to power would seem to be as follows. Their history begins with a frankly mythological account of a migration from the south to Cuzco, under the leadership of Manco Ccapac. For years the Inca, living the same life as other Andean tribes, consolidated their power in the Cuzco Valley, and then began to make their influence felt among the surrounding tribes. A career of conquest, undertaken partly as a religious crusade, eventually raised the tribe to the position of a ruling caste, whose sovereign was regarded as a god on earth. The history of this dim period is discussed fully in Joyce's book (*see* bibliography).

The first historical Inca (bearing the "royal" title of *Sapa Inca*) was Sinchi Rocca, by most authorities recorded as the "son" of Manco Ccapac, but, in Montesinos' list, separated from him by a long series of tribal rulers. His date may be set at about A.D. 1100. The list of Inca rulers in "historical" times (concerning which the early chroniclers are not quite in agreement) seems to have been as follows:

1. Sinchi Rocca.	7. Uiracocha.
2. Lloque Yupanqui.	8. Pachacuti.
3. Mayta Ccapac.	9. Tupac Yupanqui.
4. Ccapac Yupanqui.	10. Huayna Ccapac.
5. Rocca.	11. Huascar.
6. Yahuarhuaccac.	12. Atahualpa (usurper).

Under Sinchi Rocca, Cuzco was embellished with many stone-buildings, and the famous sun-temple, the Curicancha, was enlarged. It seems probable that Inca power began to make itself felt outside the Valley in a southerly direction (amongst the Colla peoples), and was consolidated by his successor. Mayta Ccapac continued the policy of expansion towards the south, and the activities of these rulers led to the annexation of a large region, extending as far as Lake Titicaca, in the reign of Ccapac Yupanqui. The next two reigns appear to have been devoted to the settlement of newly-acquired territory, but in the time of Uiracocha a crisis arose which decided the fate of the cultured peoples of South America. West and north-west of the Inca domain, the Chanca people, living under similar conditions, had built up a powerful confederation. A clash was inevitable, and the struggle was desperate; but the Inca, supported by their newly-acquired tributaries from the Collao, emerged victorious. As a result, a large expanse of territory was added to the Inca sphere, inhabited by cognate peoples, practising similar customs and religious observances, and therefore amenable to the new conditions. The annexation of the Chanca district opened the way to the coast, the conquest of which, for climatic and religious regions, was a long and laborious process. The reign of Pachacuti seems to have been devoted to a reorganization of the Inca system in view of its new colonial responsibilities. But under Tupac Yupanqui and Huayna Ccapac, the two great "conquerors" of the Inca dynasty, Inca domination was imposed throughout the highland region from Tucuman in Argentina to Quito in Ecuador. The conquest of the Nasca and Chimu peoples of the coast was a longer and more laborious process. Here religious difficulties arose owing to the unwillingness of the coastal folk to accept sun-worship, and they were reduced to submission only after a long series of campaigns which entailed the establishment of permanent forts and the cutting off of the water-supply which they obtained, by means of aqueducts, from the mountains, but by A.D. 1400 the coastal region fell under Inca influence.

Pizarro was able to succeed in Peru by the fact that he arrived just at the moment of a political "split." Huascar, the legitimate ruler, had been seized and imprisoned by Atahualpa, who claimed to be the son of Huayna Ccapac by a daughter of the ruler of Quito. According to the rules of succession, Atahualpa had no claim to the rulership, but he had the support of Ecuador. Atahualpa held Huascar captive, and assumed the divine authority. Pizarro, by a manoeuvre which was little less than an act of

treachery, captured Atahualpa, who, meanwhile, contrived the murder of Huascar. The result was that the Peruvian "empire," of which the administration centred in the ruler, regarded as a god-on-earth, fell like a ripe fruit into the hands of the Spanish invader. For chronology *see* chronological table, CENTRAL AMERICA, *Archaeology*.

Architecture.—The dawn of Peruvian and Bolivian culture produced great builders. But while the Tiahuanaco folk built in stone, the coastal peoples built in clay. The region of Tiahuanaco itself is a marvel of megalithic masonry; scattered blocks carved with a precision almost incredible as the work of a people ignorant of iron, obviously the ruins of some great architectural scheme. Megalithic building was characteristic of this early age in the high country, and the pre-Inca buildings in Cuzco (notably the triple rampart of the Sacsahuayman hill) and the Fortress of Ollantaitambo (to mention two of the most celebrated early architectural sites), belong to this cultural period. A peculiar feature of the early megalithic masonry is exhibited in the fact that the large blocks were keyed in to their neighbours by means of re-entrant angles. Consequently each block was sculptured to fit a definite position in the architectural scheme. And the masonry of this "polygonal" character was erected on a scale which, as proved by the surviving examples, represents one of the finest achievements of uncivilized man

But the polygonal method is wasteful from the point of view of labour; and the Inca developed the method of building by means of comparatively small regular blocks, cut to pattern. The principles of systematic bonding and accurate fitting were inherited from their predecessors, and, to take a single example, the apsoidal end of the great temple to the Sun at Cuzco (the Curicancha), which forms the foundation of the present Cathedral, is a famous masterpiece of early architecture.

Contemporary accounts indicate that the roofs, even of the most important buildings, were constructed of thatching supported by beams Exterior ornamentation was limited in the main to the breaking of plain surfaces by series of niches, but many, perhaps most, of the surviving stone-built ruins of pre-Inca and Inca times achieve their effect simply by their quality of massiveness and the perfect fitting of the blocks which compose them. Both the quality and the quantity of the masonry representing the two periods in the highlands mark the inhabitants as master-masons Apart from actual buildings, there exist throughout the area literally hundreds of miles of stone terracing, built for agricultural purposes on the slopes of the Andean valleys.

On the rainless coast conditions were different. Stone, in quantity sufficient for building, was lacking, and buildings were constructed in sun-baked clay (*adobe*) In this region are found enormous structures in the form of stepped pyramids (especially at Moche, in the Truxillo area), often supporting the remains of shrines All served a funerary purpose, since the early population buried their dead in what was the local "church-yard."

The art of clay-architecture attained a very high level in the Chimu period, and the great ruins of Chan-chan, near Truxillo, include long series of walls ornamented with intricate modelled designs, based mainly on textile art. Later buildings on the coast reflect the Inca conquest. The severity of Inca stone-work is reproduced in the local material, sun-baked clay.

Worship and Burial.—Traditions would seem to show that the Tiahuanaco folk worshipped a supreme god, Uiracocha, associated with rain and thunder, and therefore with fertility and creation. His worship persisted in Inca times, and he was especially associated with the southern tribes of the Inca Empire. No trace of sun-worship is found at this period. On the coast, sun-worship never existed until it was forcibly introduced by the Inca in the 15th century. The religious beliefs of the Proto-Chimu and Proto-Nasca peoples are very obscure, but probably they were much the same as those of the Chimu and Nasca, who paid reverence to certain high-gods (creator-gods and oracular divinities), to the moon and the sea, and to various lesser clan-gods, mostly in animal form, who may have been regarded as ancestors, and even possibly have had a totemic significance. The worship of special clan-gods is characteristic of the whole region in the Inca period, and, no doubt, played a more important part in the life of the ordinary man than the cult of the more remote high-gods. Of the latter, two seem to have been preëminent on the coast. Here the great creating divinity was Pachacamac, counterpart of the highland Uiracocha, whose great shrine exists in ruins to-day at the site which still bears his name. Another coastal deity of great importance was the oracular god Rimac, whose temple (from which the modern Lima receives its name) was the resort of pilgrims from distant regions in the Inca period.

The whole of Peruvian religion, in Inca times, is connected with the word "Huaca," belonging to the Quichua dialect spoken by the Inca, and employed throughout their empire as the official tongue. There is no one word in English which can convey its meaning It means "holy" in the fullest sense (and was applied to the highest and most mysterious gods). Tribal gods and clan gods were "huaca," and the meaning of the word was extended to include objects which were regarded as uncanny, or merely unusual, such as a queerly-shaped rock, or a man with a hare-lip The tribal *huaca* of the Inca was the Sun, and their campaigns of conquest were in a sense crusades, to elevate the tribal god to a paramount position amongst the neighbouring tribes. They made no attempt to suppress local cults, but planted temples to the Sun in conquered provinces and compelled the subject tribes to conform, at least outwardly, to "state-religion" In the coast region, life was one long struggle against drought and the Sun was no benefactor. The long resistance made by the inhabitants of the coast to the Inca invasion appears to have been based on unwillingness to accept sun-worship as an "established church"

Lowest in the order of *huaca* came the personal and household fetishes, known as *conopa* on the coast, and *chanca* in the highlands, usually small stones of peculiar shape or colour, or any unfamiliar object Many of the ruling Inca possessed personal fetishes or "familiars," called *huauqui*.

But throughout the region the cult of the dead occupied a very important place in religion. Many of the tribal and clan *huaca* were regarded as ancestors, and a similar sanctity attached to the mortal remains of human forbears The burial rites afford an interesting parallel with those of Egypt. The Egyptian process of mummification arose from the local climatic conditions. The fact that bodies, buried in dry sand, did not decay, led to the idea that the preservation of the body was a matter of importance, and so to the evolution of special means to arrest corruption. The dry air of the highlands in Peru and Bolivia, and the arid atmosphere of the coast, provided a parallel environment and produced similar results. In either region the bodies of the dead became desiccated, and in certain instances the preservative tendencies of the climate were assisted by the evisceration of the corpse before burial. The body was usually arranged in a contracted position (unlike the Egyptian mummy) and, after being wrapped in various folds of textile or netting, deposited in a cave (highlands), or a communal grave or "church-yard" (coast). The "mummies" of the ruling Inca were preserved in the great Sun-Temple at Cuzco, where they were seen by the first Spanish invaders. These "mummies" were *huaca* of a high order, and those of important individuals were paraded at certain festivals to the dead. The word *huaca* exists today as applied to the pottery remains discovered in aboriginal burial-grounds.

Arts and Crafts.—The skill of the Peruvians in the cutting of stone is illustrated in the section on architecture. The delicate flaking characteristic of the Maya area is not found here, but the manufacture of axes, mortars and other vessels, by means of polishing, attained a very high degree of proficiency. It is probable that stone was worked with stone, though certain metals, such as gold and copper, were known from the earliest periods in the highlands. The copper was in fact a bronze, probably accidental, but was worked both by casting and hammering In Inca times, at any rate, metal was smelted in furnaces (*huaira*) fanned by the sea-breeze which blows regularly at night on the western slopes of the Andes. Gold and silver were cast and hammered, and these metals, according to contemporary accounts, were used in combination; the Inca had gardens in which flowers were imitated in the precious metals. Metallurgical skill extended to the coast in

Chimu times, and the narrow silver vases discovered in burials of this period exhibit a perfection of technique.

For archaeology, however, it is the potter's art which is the most important, in so far as the sequence-dating of the successive cultural periods is based mainly on the various styles of ceramic art found in stratified layers at certain sites. The Peruvian potter was ignorant of the wheel, and his vases were built by the "coiling" process, at any rate in early times. Moreover, Proto-Chimu pottery is almost unique in America owing to the extreme realism of its modelling. Vases in the form of human heads and figures were modelled on lines which suggest that they were actual portraits.

In the dry atmosphere of the coast evaporation was rapid, and water was precious. A closed vessel with narrow spout was necessary for its preservation. The difficulty of pouring from a single narrow spout led to the invention of the loop-handle, which permitted the introduction of air by one branch, while the liquid issued from the other. Proto-Chimu vases, apart from their realistic modelling, are distinguished by a marvellous perfection of form. They are usually coated with a creamy slip, on which designs, in more or less conventional style, have been painted in terracotta slip. A black ware is also found, though not in large quantities. If the Proto-Chimu pottery was supreme in modelling, that of the Proto-Nasca folk was supreme in colouring. No people, living under similar primitive conditions, have ever held at their command so wide a range of tints in slip-decoration. Modelling is rare and inferior to that of the Proto-Chimu, but the qualities of paste and shape are equal.

Designs in the Tiahuanaco style, but in the colours of the coast, have been found at various sea-board sites, notably Pachacamac, and provide important evidence that the Tiahuanaco folk conquered the coast at least as far as this point. The peculiar ware of the Recuay valley, with decoration suggesting both Proto-Chimu and Tiahuanaco influences, has not yet been properly studied.

The Nasca period, which succeeded the Proto-Nasca, was not so successful as a revival. The brilliant colours of the earliest period were lost, and decoration consisted in the main of rather small-scale designs derived from textile art. The Inca, inheritors of the Tiahuanaco culture, invented certain pottery shapes, one of which, known as the "aryballus" (with flaring neck and pointed base, rather reminiscent of certain Etruscan patterns) is peculiarly characteristic. Inca ware is extremely good in quality; the coloured decoration is rich, but low in tone, and limited in range, while the patterns are mainly geometrical.

The weavers of this region displayed a proficiency almost equal to that of the potters, and it has been said that, if the art of weaving were suddenly eliminated from the Old World, it could be reconstructed from a study of ancient American textiles. This is not quite true, because no specimen of "twilled" technique has been discovered. The earliest woven fabrics appear to have been constructed on a warp which was kept extended by a band encircling the back of the weaver. The weft was put in by hand, by means of wooden needles bearing threads of different colours. The technique was that of tapestry, but there were local variations. In the area covered by the Proto-Chimu and Chimu cultures, the weft was absolutely discontinuous, with the result that slits appeared in the fabric at the points where the division between colours ran in a vertical direction (like the oriental "kelim"). For this reason most of the designs ran on diagonal lines. In the Tiahuanaco-Inca and Proto-Nasca-Nasca area, these slits were obliterated by interlocking the wefts of converging colours.

The colours of the early textiles show great range and brilliancy, and certain specimens, discovered in the burial-grounds of the Nasca region, fringed with a kind of "crochet" work, are remarkable examples of design and technique. Whether the principle of the heddle was known in early times is uncertain, but this appliance was certainly employed in the later period. In Chimu times double-faced cloths, with reciprocal patterns, were woven on a simple loom equipped with two heddles and two shed-sticks; a process involving two warps and two wefts (for further details *see* bibliography, especially Joyce's book and later works).

Social Life.—The Inca rule was a form of state-socialism, based on the idea that the sovereign was the earthly representative of the Inca tribal god, the Sun. In the course of expansion, and the meticulous organization of conquered provinces, the Inca, from a tribe, became an official caste, constituting, eventually, a huge bureaucracy. The inhabitants of the highlands acquired a mentality remarkably responsive to discipline. The expansion of Inca rule was, to the populace, merely a change of overseers.

The communistic system seems to have dated from the earliest times; under Pachacuti it was adapted to the needs of "colonial expansion." Eventually the "empire" was divided into provinces, each under the control of a hereditary *Curaca* (often a local chief, confirmed in his office owing to ready acceptance of the new regime), and a hierarchy of officials ranging from sub-chiefs to subordinate inspectors, whose supervision was limited to a few families. Intensive supervision was a condition of the peculiar form of government. All produce, agricultural, pastoral or industrial, was fundamentally state property. Trade was practically non-existent. Labour, manual, operative and official was "state-tribute," and some form of "labour" was exacted from every member of the community. Lands were apportioned for cultivation in accordance with the size of families, but the produce was essentially state property. In fact the whole of the produce of the Inca empire was pooled, and distributed according to a regular system. This system had certain merits and corresponding defects. It permitted an equal food-supply throughout the empire; the surplus of the maize-crop, for instance, in the fertile valleys, providing for the upkeep of a large herdsman population in the sterile uplands; and also for the relief of drought.

Craftsmen (weavers, potters and metal-workers), though not entirely exempt from agricultural work and *corvée* labour (involved in the construction of roads and state-buildings) were, in the main, supported by the agricultural population, who, in their turn, received a proportion of textiles and other manufactured goods. The distribution of raw material, as well as manufactured articles, was carried out on a regular system, and, to take one instance, the weavers received a regular allowance of cotton and llama (or alpaca) wool, from which they were expected to produce a certain amount of woven material. Knowledge of the carefully organized interchange of produce is based mainly on Garcilasso's account, which is probably overdrawn, but there is no doubt that the main lines are correct. The system was perhaps less perfect than appears from his description, yet there is no question of the drastic measures employed by the Inca in the organization of conquered territory. Whole sections of the population were transferred from one part of the "empire" to another. Such enforced "colonists" were known as *mitimaes,* and the practice served a double purpose, political and economic. In the first place it was a safe-guard against insurrection; in the second, it provided for the population of uninhabited areas.

Under a system of this type a rigid survey of the population was a matter of first importance, and a careful "census" was made from time to time, the records preserved on the knotted cords known as *quipus* (*qv.* and *see* Locke, *The Ancient Quipu*). It was equally important that there should be no shifting of population, except under state supervision; consequently an individual born to a certain occupation in a certain locality, could, in normal circumstances, neither change his trade, move from his village, nor even marry outside his local group. The system involved the absolute suppression of personality or enterprise, acceptable to the local psychology, but intolerable to Anglo-Saxon concepts.

Behind the state-organization, lay a clan-system, still imperfectly studied, and obviously far older than the imposed Inca regime. Local family-groups, which appear to have been true clans (known as *ayllu*), practising the cult of a common *huaca,* existed within the tribal complex of the Peruvian aborigines.

The administration of the enormous length of mountainous territory administered by the historical Inca necessitated rapidity of communication, and a service of professional "runners" was maintained, who traversed the country in relays, from rest-house to rest-house, along the roads which are still traceable from Quito to Northern Argentina. In the highlands these tracks are often in

the form of stairways cut in the face of precipices.

Among the populace marriage was arranged, under supervision, within the local group. But the ruler himself was limited to certain restrictions. He was allowed to maintain a number of concubines, but, at any rate in theory, his normal consort (*Ccoya*) was his sister, who alone could bear him a successor. This seems to suggest that rank followed the female line, and that Peruvian inheritance was based on a matrilineal system. Here again, chance was on the side of the Spanish invader. Pizarro arrived just at the moment of a grave politico-religious crisis. Huayna Ccapac had died recently. His legitimate heir, by his sister, was Huascar. But a pretender, who asserted that he was the son of the late "emperor" by a daughter of the chief of the lately added province of Cuzco, had assembled a force of Ecuadorian mountaineers, and, by a *coup-de-main,* had captured Huascar Pizarro, by means which it is difficult to describe save as sheerly treacherous, seized Atahualpa. Atahualpa gave orders for the execution of Huascar, and these orders were obeyed The motive power behind the Inca empire therefore ceased to exist Huascar was dead, and Atahualpa, who by force of arms might have taken his place, was a prisoner. The Inca organization was for the moment like a clock without a mainspring, though the works were otherwise unimpaired. Yet the organization was so complete that when the Spaniards by a lucky random stroke, held in their possession the person of the only possible claimant to the position of divine ruler, they were able to set the wheels going to their own advantage Naturally there was a certain amount of opposition, but Pizarro had little to face in this respect compared with Cortez. His main difficulties lay in the dissensions which arose among the Spaniards

Allusion may be made to the system of training which was imposed on boys of prominent Inca families in the capital Cuzco. Lads of prominent families, destined to the higher posts in administration and the army, were subjected to a severe training of a "public-school" nature (which the heir to the throne also underwent), and submitted to tests of a very severe nature The culminating ceremony was a race from the sacred Huanacauri hill to Cuzco, after which candidates who had "passed" received certain insignia of "nobility," including the ear-ornaments which distinguished the ruling caste

The Lower Cultures of South America.—In the north-western provinces of Argentina, amongst the Diaguite people, remains have been found which display strong influences emanating from the Tiahuanaco culture, and, subsequently from the Inca Inca influence is also evident in northern Chile Elsewhere material culture was at a low stage, though the beautifully flaked arrow-points of jasper and chalcedony, of the lower Chilean coast are unsurpassed in the history of stone-technique A few rather remarkable stone-carvings have been found in the Santa Caterina province of Brazil, and a very interesting class of decorated pottery has been discovered in some quantities on the island of Marajo in the Amazon delta, which appears to have been the burial-ground of a vanished Arawak population.

Ecuador.—At the time of the Spanish conquest, practically the whole of Ecuador had fallen under the domination of the Inca, and arts, industries and social life had been organized on the Inca system. Quito had risen to almost the rank of a second capital of the Inca empire, and by troops collected in this region Atahualpa was enabled to attempt to oust Huascar from the rulership. Before the Inca conquest, a contrast, remarkably similar to that in early Peru, between the culture of the coast and highlands respectively, is indicated by the archaeological remains. The pottery of the coast, in its realistic tendencies, displays a certain similarity to that of the Proto-Chimu; while the ware of the highlands shows affinities with that of Colombia, especially in the prevalence of reservation on patterns in the ground by means of wax-painting or some analogous process. History is confined to a few surviving traditions, mostly of a mythological character; but containing certain "historical" details which may be summarized as follows A tribe known as Cara arrived on the coast in rafts (the nature of the craft suggests a coasting voyage), under a chief termed Scyri. Later they migrated to the uplands, where they amalgamated, first with the Quitu tribe, and subsequently with the Puruha. Later the warlike Canari and the Palta became members of the nascent "empire," which at the time of the Inca conquest included practically the whole of the Ecuadorian highlands

Bibliography—A fairly complete archaeological bibliography of South America is given in the work of Beuchat mentioned in the last section, and in T A. Joyce, *South American Archaeology* (1912), which deals at length with the history and culture of the early tribes Though mentioned in the above bibliographies, especial attention may be called to the annotated translations by Sir Clements Markham of certain early chroniclers, published by the Hakluyt Society of London; viz. Garcilasso de la Vega (1871 and 1879), Molina, Salcamayhua, Avila and Ondegardo (in one volume 1873), Cieza de Leon (1864 and 1883) and Sarmiento (1907) *See* also the translation of Montesinos, in the same series, by P A Means (1920) But a considerable bulk of archaeological literature has been published, chiefly in the form of monographs and papers in scientific journals, since the compilation of Beuchat's and Joyce's bibliographies. These cannot be given in detail, but the most important authors are Max Uhle (for Peru and Ecuador, papers printed from time to time in those countries) and detailed summaries of the results of Uhle's excavations made by A. L. Kroeber, A. H. Gayton and W D. Strong (University of California Publications, vols. 21 and 24). L L Locke, *The Ancient Quipu* (American Museum of Natural History, 1923); and E Nordenskiold, *The Secret of the Peruvian Quipus* and *Calculations with Years and Months in the Peruvian Quipus* (both Goteborg, 1925), describe the Ancient Peruvian method of recording by means of knotted strings, so far as elucidated The writings of J. C Tello (in the publication *Inca*, Lima, Peru), of J. Jijon y Camaano (published in Ecuador, notably *La Religion del Imperio de los Incas*, 1919), and respecting Chile, of R E Latcham and Max Uhle (published locally), all demand attention The literature dealing with the archaeology of the West Indies is adequately covered by the bibliographies appended to the work of Beuchat (mentioned above), and to T A Joyce's *Central American Archaeology* (1916), the latter of which deals comprehensively with the culture of the Antilles. Since the publication of these works, two others of importance have appeared, M R Harrington, *Cuba before Columbus* (Museum of the American Indian, 1921), and Sven Loven, *Über die Würzeln der Tainischen Kultur* (Goteborg, 1924) The abundant footnotes in both these publications practically constitute bibliographies Shorter papers, in scientific publications, are too numerous to mention singly Of these journals perhaps the most important are —The *Journal of the Royal Anthropological Institute;* the *Journal de la Société des Américanistes de Paris;* the *Zeitschrift fur Ethnologie*, the *American Anthropologist; Inca* (Lima, Peru) The *Reports* of the International Congress of Americanists, in particular, present a wide range of archaeological material, though the standard of the papers printed varies considerably Access to current literature is best obtained through the *Bibliographie Américaniste*, compiled from time to time by P Rivet and published in the *Journal de la Société des Américanistes de Paris,* Dr Rivet's own publications ranking amongst the most important contributions to archaeological literature (T A J)

ETHNOLOGY

Practically all the definite data available indicate that the aboriginal population of South America was derived from that of the northern continent, by successive drifts coming by way of the isthmus of Panama and possibly to a lesser extent by way of the Antillean chain from Florida It has been urged by some that a trans-Pacific origin may, at least in part, be assumed In spite, however, of a few striking cases of cultural parallelism, the practical difficulties involved are so great that one must regard this theory as still unproved An occasional canoe from Oceania may, it is true, have reached the South American shores, but the racial significance of such cases would be negligible

The older theory of the origin of the American Indians regarded them as belonging to one single racial type, designated as Mongoloid Such variations as were recognized were thought to be merely local forms of no significance. Evidence has, however, in recent years been coming to light which tends to make this view more and more impossible. The crania found at Lagoa Santa in Brazil, at Paltalcalo and Puñin in Ecuador, in Lower California, the islands off the southern Californian coast, and among the Basket-makers of the south-west, etc, with their strikingly Melanesian and Australoid characters, have led many able anthropologists to believe that at least two fundamentally different racial elements were present in the New World. Of these the Melanesian-Australoid type is the older, as shown both archaeologically and by its marginal position A Caucasoid and even a Negroid factor are also possibly present. The peoples of the New World are, therefore, like those of the old, almost

certainly of complex racial origin.

Linguistic Stocks.—The primary classification of the American Indians is usually based on language. In the northern continent some seventy odd different linguistic stocks are officially recognized by the Bureau of American Ethnology, although the investigations of the last generation have shown that without much doubt this number should be largely reduced. For South America the linguistic data available are far less abundant and satisfactory, but taking the evidence as it stands, the latest attempt to classify the tribes of the continent on the basis of language (A. F. Chamberlain, "Linguistic Stocks of South American Indians," *American Anthropologist* [N.S.], vol. xv.), recognizes 83 linguistic stocks. Just as in North America, a considerable number of these are actually related, either to each other, or to one or other of the large stocks, such as the Arawakan, Chibchan, Cariban, Tupian, etc. These and other large stocks have spread widely, the Arawakan being perhaps the greatest wanderers, representatives being found from Bolivia to Cuba.

The linguistic stocks as recognized by Chamberlain are as follows:—

Alikalufan	Coconucan	Otomacan
Allentiacan	Corabecan	Otuquian
Andaquian	Cunan	Paniquitan
Apolistan	Curucanecan	Panoan
Araucanian	Enimagan	Peban
Arawakan	Esmeraldan	Piaroan
Ardan	Goyatacan	Puelchean
Atacamenan	Guahiban	Puinavian
Aymaran	Guaraunan	Puquinan
Barbacoan	Guatoan	Quichuan
Betoyan	Guaycuruan	Salivan
Bororoan	Itonaman	Samucan
Calchaquian	Itucalean	Sanavironan
Cañarian	Jivaran	Tacanan
Canichanan	Jurian	Tapuyan (Ges)
Carayan	Lecan	Ticunan
Cariban	Lorenzan	Timotean
Caririan	Lulean	Trumaian
Cayubaban	Mainan	Tsonekan
Changoan	Makuan	Tupian
Chapacuran	Matacan	Uitotan
Charruan	Miranhan	Uran
Chavantean	Mocoan	Yaghanan
Chibchan	Mosatenan	Yaruran
Chiquitan	Moviman	Ypurinan
Chocoan	Muran	Yuncan
Cholonan	Ocoronan	Yurucarean
Chonoan	Onan	Zaparan

(*See* also SOUTH AMERICAN LANGUAGES.)

Social Organization.—Three main types of political organization may be recognized among the South American Indians. The simplest is found among the more primitive nomadic or seminomadic tribes such as those of the Tapuyan peoples of the Brazilian highlands, many of the smaller stocks of the Amazon-Orinoco basin and of the Chaco and Pampas region southward to Tierra del Fuego. There is no centralized authority, no true tribal chiefs; the people are organized in small local and independent units, submitting themselves only in case of war to the effective leadership of the best fighters. Above these come the majority of the tribes of the region east of the Andes, among whom, as relatively sedentary communities, the tribal unit is more clearly organized, and village and occasionally tribal chiefs have acquired a considerable measure of authority, often quasi-hereditary in character. In the Andean highlands and along the Peruvian coast the position and power of the chiefs had advanced to such an extent that in several instances, such as among the Chibchas of Colombia, the Caras of Ecuador and the Yuncas and Incas of Peru, there existed an actual monarchical type of government. In Peru, this was in some measure complicated by the elaborate communistic organization of the mass of the population, which was, however, largely imposed upon them by the ruling Inca caste.

The typical totemic clan system which characterized the social structure of large parts of North America was apparently less widely and less clearly marked in the southern continent. This may be more apparent than real, since data are less abundant.

As regards marital relationships, one finds a comparatively wide range from the usual monogamy of the more primitive tribes to the highly developed polygamy of the Chibchas and Incas, where the ruling chiefs or kings possessed harems numbering several hundreds. Secret society organizations, military and otherwise, seem to be rather less common than in North America.

Mode of Life.—Among the South American Indians one may find every gradation between the purely nomadic tribes depending wholly on fish, game and wild vegetable products, represented by the Maku or Botocudos of the forest region, the Puelche and Tehuelche of the open pampas or the Onas of Tierra del Fuego, to sedentary agriculturalists, such as the Guarani tribes of Paraguay, or the higher cultured peoples of the Andean highlands, such as the Incas, Yuncas and Chibchas of Peru and Colombia. There were, however, relatively few tribes wholly destitute of agriculture, and the Incas, with their elaborate terrace irrigation, and the Yuncas of the Peruvian coast, with highly developed irrigation and the use of fertilizers, had carried the art to a remarkable stage of perfection. While maize was the major crop along the Peruvian coast and in portions of the Andean highlands, it was less grown in the tropical forest region, where in some sections it was even unknown. In this tropical area manioc was the chief agricultural product. Two different varieties were known, the poisonous and the non-poisonous, the former being rendered harmless by a simple and ingenious process. In the colder highlands the common potato was largely grown, the sweet potato being raised in the warmer sections of the continent. The quinoa was grown in the coldest regions of the highlands, where other crops would not mature. Nearly all the South American tribes, except those of the extreme south, prepared and consumed large quantities of fermented drinks, made from maize, manioc, fruits and palm-sap. In the Andean region, from Bolivia northward and east into the borders of the forest area, the dried leaves of the coca plant were chewed, in some cases mixed with lime, and widely throughout the western portion of the Amazon-Orinoco basin, various kinds of narcotic snuffs were inhaled by means of Y- or V-shaped tubes of bone or cane. Tobacco was smoked in the form of cigars or cigarettes throughout most of the tropical forest region, but pipes were, with few exceptions, in use only in Argentina. The use of tobacco seems to have been practically unknown in Peru and Bolivia and was rare along the Pacific.

Dress ranged from the complete nakedness of some forest tribes of Brazil, through the use of kynodesmy (penis supporters) and various forms of breech-clouts, aprons and kilts of tapa, palm-fibre or cotton, to the elaborately ornamented cotton or woollen mantles, ponchos and skirts of the peoples of the Andean highlands. The Yaghan of Tierra del Fuego, despite their harsh and cold environment, wore only a sealskin hung over the windward shoulder. The most characteristic feature of personal ornament was probably the labret worn in the lower lip. This was usually either in the form of a rod-like pendant or a plug of varying diameter, and was worn (chiefly by men) over a large portion of the northern half of the continent. The ear-lobe and nasal septum were also often pierced and ornaments of bone, wood or metal worn therein. On the Ecuador coast the teeth were inlaid with gold, after the fashion prevalent in parts of Central America. Tattooing was less in use than body painting, the latter type of decoration being sometimes applied by means of pottery or wooden stamps, carved or moulded in patterns. The dwellings of the forest nomad tribes were quickly constructed temporary shelters of leaves or bark, whereas the tribes of the open pampas and Patagonian plains made use of lean-to tents of skin, of the "toldo" type, open on the side away from the wind. The houses of the sedentary population were usually wholly of wood and thatch, some circular with conical roof, some rectangular with gable roof; some very small and used by but a single family, some large and communal, accommodating from 50 to 100 persons.

The bow was the principal weapon of the region east of the Andes, but was unknown or little used in the highlands or on the Pacific coast. Distinctive of South America was the use of the blowgun with poisoned darts, this weapon being in use over a large portion of the western Amazon-Orinoco basin, and reaching

the Pacific coast at one or two points in the north-west. Clubs took two main forms, the two-handed wooden broad-sword or "macana" used in the north, and the shorter, stone or metal-headed club of the Inca empire. The throwing-stick, similar in principle but differing in details from the Mexican "atlatl," was widely used in the north, and has been found in early archaeological sites as far southward as northern Chile The nomad hunting tribes of the pampas made much use of the bolas, composed of two stones attached together by a short cord, in hunting the guanaco and the rhea or South American ostrich.

The dog was a well-nigh universal possession as a domestic animal. In the highlands of Peru and Bolivia the alpaca and llama were also domesticated, the former for its wool, the latter primarily as a beast of burden. Here also land transport was greatly facilitated by the remarkable system of roads built by the Incas, paved in places, and crossing streams by suspension bridges, and over which an elaborate courier service was maintained Bark and dug-out canoes were widely in use, but were supplanted on the Pacific coast from northern Chile nearly to Panama, by reed or log "balsas" or rafts, often furnished with sails In southern Chile the "dalca" or three-plank boat was in use.

Religion.—The methods of disposal of the dead comprise almost every known form. Simple inhumation was probably the commonest, the deep shaft graves of Colombia and Ecuador marking its highest development, as these in some cases attained a depth of 50 or 60 feet In this region mounds were sometimes built over the grave. Platform burial, cave burial and urn burial were fairly commonly employed. In the Andean region various methods of preserving the body were tried, desiccation in the dry, cold air; smoking over a fire, etc. The well-known Peruvian "mummies" are, like those of the south-western United States, primarily the result only of natural desiccation Some of the Orinoco and upper Amazon tribes who practised inhumation, were accustomed to exhume the bones after a time, burn and powder them, and then drink the powder mixed with their fermented drinks The shaman or medicine-man was, among all except the tribes of highest culture, an outstanding figure, a curer of disease by sucking, blowing or the use of charms, a sorcerer, diviner and intermediary between man and the supernatural world Often he was supposed to have the power of turning himself into a wild animal at will. In the higher Andean cultures the shaman developed into an elaborate priesthood

Ritual, involving mimetic and other dances, sacrifice and prayer, presents a wide range of complexity. Mimetic dances, with or without the use of masks, were characteristic among many peoples of the western and central parts of the tropical region, and more commonly with animal and bird skins for disguises, played a large part in the ceremonies of the Incas and other folk of the Andean cultures In Venezuela and far to the southward, the whipping-dance was widely spread, in which the participants lashed each other's legs with whips. Puberty initiation ceremonies, very often involving severe ordeals, were also found widely, all the way from Panama to Tierra del Fuego. Sacrificial offerings were developed mainly in the Andean section. In Colombia, these were most commonly of gold objects, or parrots to whom a prayer or message had been taught. Among the Incas, large numbers of llamas were offered. Human sacrifice, if we except the killing of war captives, was practised occasionally; in some cases it was restricted mainly to infants, as in parts of Colombia and north-western Argentina. Mature victims were sometimes tied to a pole and shot to death with arrows, as in middle America. In Peru and more doubtfully farther northward, the heart was sometimes torn out in the Mexican fashion. The practice of head-hunting (*q.v*) and the preservation of head trophies was widespread from Colombia to Peru, and reached its highest development in the region of eastern Ecuador, with the curiously shrunken heads prepared by the Jivaro (*q.v.*) and other tribes of that area.

Temples and purely religious structures were also, in the main, confined to the area from Colombia to Peru. In the former region they were of perishable construction like the dwellings, although often decorated with a great wealth of gold. In Peru and about Lake Titicaca, they were massively built of cut stone.

The use of images was confined to the Andean highlands, as was incense. Among the great majority of the tribes worship and ritual were addressed to tribal deities of the simpler sort, or to totemic or ancestral spirits, or to local deities of mountain or stream. In Peru, these features were strongly marked, although overlaid by the sun-cult of the Incas imposed by them on the conquered peoples The figures of some of the creator gods, notably of the Incan Uiracocha or Pachacamac, "the soul of the Universe" attain, however, a higher stage. A notable feature of the mythology of the highland tribes is the appearance of a fair and shining culture-hero, who disappears, promising to return at some later time Something of the initial success of Pizarro and his followers in Peru seems to have been due to their being regarded as divine beings, fulfilling prophecy.

SOUTH AMERICAN LANGUAGES. The languages of South America are for the most part still very imperfectly known. and the number of linguistic stocks considered independent of and unrelated to any linguistic family in the New or Old World is reckoned at 75. For many of them we have only vocabularies often very scanty and of doubtful accuracy Grammars are rare and nearly all compiled on the model of Latin by missionaries who did not realise that the methods of Latin are totally unsuited for describing languages with essentially different structure and syntax Finally for most of the languages we have no ancient material. On the Pacific side the main languages are as under:

Chibcha was once spoken almost all over Colombia up to the frontier of Nicaragua and northern Costa Rica, with representatives as far as the latitude of Guayaquil in Ecuador, prior to the Inca invasion, when Chibcha speech was ousted by Kichua on the Andean Ecuadorian plateau

Kichua.—The language of the Inca, Kichua or Runa-Simi, is still spoken by Indians on the high plateau of Ecuador and Peru, in Bolivia (Cochabamba, Chuquisaca and Potosi), in the north-west of the Argentine (Jujuy, Santiago del Estero) It is the only language in America which was an element of civilization before the Discovery, when it was the instrument of an invading culture brought by an organized conquering people Inca imperialism forced it on the vanquished peoples, then the Catholic missionaries continued and completed the work of the overlords of Cuzco.

Aymara.—Speakers of Aymara exist in Peru in two provinces of the department of Puno, in the departments of Arequipa and Moquegua, in Bolivia. Before the spread of Kichua it was more widely diffused and the builders of the famous monuments of Tiahuanaco almost certainly spoke it.

Araukan.—This language still exists in Chile between the Pacific and the Andes, between the 27th and 43rd degrees of latitude and in the Argentine up to Buenos Ayres.

Choko was spoken on the Pacific side between eight and four degrees North and Esmeralda on the north coast of Ecuador

On the Atlantic side at the time of the Discovery the people were at a low level of civilization and we find there several large language families and a great number of small independent groups.

Tupi-Guarani.—In the north this language was spoken in Guiana (Oyampi and Emerillon), in the west up to the slopes of the Andes and in the plains west of the Bolivian Grand Chaco (Chiriguano). Southwards it is still spoken throughout Paraguay. In the east, tribes of this speech, at the time of the Discovery,

occupied the largest portion of the Brazilian coast up to the mouths of the Amazon.

Old Tupi or Abañeenga had two dialects, that of the south or Guarani, the parent of modern Guarani, as still spoken in Paraguay and adjoining territories, and the northern, Tupi, the forerunner of modern Tupi or Neeñgatu, the "lingoa geral" used in commerce and missionary work throughout the Amazon basin.

Carib.—A wider area was covered by the Carib, whose place of origin is thought to have been the region between the Upper Xingu and the Tapajoz, whence they spread northwards to the Lesser Antilles and to the southernmost point of Florida. They reached the Andes on the west and small groups entered Colombia (Motilon, Opon and Carare Indians) and Peru in the Jaen area (Patagon). On the east they found the coast at Guiana (Oyana, Rukuyen, Kaliña, Galibi, etc.).

Arawak.—The Arawak area is almost identical with that of the Caribs, and in some cases they seem to have migrated together. Their centre of dispersion was somewhere in the Venezuelan-Brazilian area, about the basins of the Orinoco and the Rio Negro. Arawaks were found in Florida and southwards in Paraguay, in Peru (Uru and Pukina) and in the east at the mouths of the Amazon (Araua). So far this form of speech is the earliest of the forms found in the Peruvian-Bolivian area, being earlier than Aymara, which was ousted by Kichua.

Pano.—Of the three geographical groups of this family, the most important is found on the south bank of the Amazon, from the Jutahy east to the Huallaga west, on both banks of the Ucayali from its mouth to parallel 10° and the right bank of its tributary, the Urubamba, in the entire basin of the Upper Jurua and the sources of the Purus. The second group covers the basin of the Inambari, while the third group holds the banks of the Mamore, the Beni and the Madre de Dios between 9° 15′ and 12° 30′ latitude and 64° 45′ to 67° 30′ longitude.

Ge.—This family probably represents one of the oldest elements in South America and extends over the whole of the southern half of the Brazilian plateau reaching Xingu on the west and the Atlantic coast on the east, whence its speakers were expelled by Tupi-Guarani in the 15th century. The classification of Ge speech has yet to be accomplished and is one of the most urgent linguistic tasks awaiting the Americanist.

Tukano.—The first or eastern of the three geographical groups of the Tukano family covers the basins of the Uaupes, Curicuriary and Apaporis. The western group occupies the entire basin of the Napo from its junction with the Amazon up to the mouth of the Aguarico, along the latter river, along the Putumayo from its source to its junction with the Yaguas, along the upper Caqueta to about the 74th degree longitude. The northern group is found at the sources of the Manacacia, a tributary of the Meta.

Katukina.—An immense area south of the Amazon between 72° 30′ and 62° 30′ longitude and between 4° and 9° latitude is occupied more or less continuously by this family.

Puinave.—Like the Ge group the speakers of the Puinave languages are among the most primitive peoples of South America and represent a very ancient element of the population. The Puinave are found in the basin of the Inirida and the nomadic Maku between the Rio Negro and the Yapura, between 69°30′ and 61° 45′ longitude.

Guaykuru.—The Guaykuru languages are spoken by a series of tribes along the banks of the Paraguay, the Parana and their tributaries and in the Chaco, *e.g.*, Mbaya-Guaykuru, Guachi, Payagua, Toba, Mokovi, Abipon.

Matako-Mataguayo.—In the lesser Chaco a compact group is formed by the following: Mataguayo, Matako, Vejoz, Choroti, Ashluslay, etc.

Unclassified Languages.—All over the western portion of South America are spread isolated languages, such as Jirajara, Timote, Yaruro, Otomak, Guahibo, Saliba, Maku, Shiriana, Auake, Kaliana, Guarauno in Venezuela or on the borders of Brazil and Venezuela; Koche, Kofane, Zaparo, Chirino, Kahuapana, Cholona, Amuesha, Tuyuneiri, Leko, Moseten, Yurakare, along the eastern slopes of the Andes and the upper tributaries of the Amazon from southern Colombia to Bolivia; Witoto, Yuri and Mura on the upper and middle Amazon; Mobima, Kayuvava, Kanichana, Itonama, Chapakura, Mashubi, Huari, Nambikuara, Karadja, Trumai, Bororo, Chiquito, Guato, Samuku, Maskoi, Enimaga and Shavante in central and southern Brazil, in eastern Bolivia and in Paraguay; Kariri in eastern Brazil; Charrua formerly spoken in Uruguay; Vilela-Chulupi, Sanaviron, Allentiak, Het and Puelche in the Chaco and in the Argentine Plain.

Australian Affinities.—Of the three southernmost languages of the continent, Alakaluf, Yahgan and Chon, only the last, now spoken by the Patagonians or Tehuelche of the Argentine Pampa, and by the Ona in Tierra del Fuego, has been identified and is found to belong in respect of vocabulary to Australian languages. The migration of Australians to America must have taken place via the Antarctic during the post-glacial optimum when the climate of those regions was sensibly more favourable than now, a period counted by geologists as not less than 6,000 years distant. (Rivet, *Bulletin de la Société de linguistique de Paris*, t. xxvi. 1–2, pp. 23–63, 1925; *Compte-rendu sommaire des séances de la Société de bio-géographie*, Paris, 3ème année, no. 18, séance Feb. 19, 1926.)

Although links have been established with Australia and in the north with Malayo-Polynesian Australasian (*e.g.*, the Hoka group) and with Sino-Tibetan (*e.g.*, the Na-Dene group), linguists have failed to prove any relationship between the languages of North and of South America or with those of Central America. Information is also needed about the dying languages before they have completely disappeared.

BIBLIOGRAPHY.—*Les Langues du monde*, by a group of specialists under the direction of A. Meillet and Marcel Cohen (1924); W. Schmidt, *Die Sprachenfamilien der Erdkreise* (1926).

SOUTHAMPTON, HENRY WRIOTHESLEY, 3RD EARL OF (1573–1624), one of Shakespeare's patrons, was the second son of Henry Wriothesley, 2nd earl of Southampton, and his wife Mary Browne, daughter of the 1st Viscount Montague. He was born at Cowdray House, near Midhurst, on Oct. 6, 1573, and succeeded to the title in 1581, when he became a royal ward, under the immediate care of Lord Burghley. He entered St. John's College, Cambridge, in 1585, graduating M.A. in 1589; and his name was entered at Gray's Inn before he left the university. At seventeen he was presented at court, where he made friends with the earl of Essex, and received extraordinary marks of the queen's favour. He became a munificent patron of poets. Nashe dedicated his romance of *Jack Wilton* to him, and Gervase Markham his poem on Sir Richard Grenville's last fight. His name is also associated with Barnabe Barnes's *Parthenophil and Parthenope*, and with the *Worlde of Wordes* of John Florio, who taught him Italian. But he is best known as a patron of the drama and especially of Shakespeare. *Venus and Adonis* (1593) is dedicated to Southampton in terms expressing respect, but no special intimacy; but in the dedication of *Lucrece* (1594) the tone is very different. "The love I dedicate to your lordship is without end . . . What I have done is yours; what I have to do is yours; being part in all I have, devoted yours." Nicholas Rowe, on the authority of Sir William Davenant, stated in his *Life of Shakespeare* that Southampton on one occasion gave Shakespeare a present of £1,000 to complete a purchase.

If the sonnets were addressed to Southampton, the earlier ones urging marriage upon him must have been written before the beginning (1595) of his intrigue with Elizabeth Vernon, cousin of the Earl of Essex, which ended in 1598 with a hasty marriage that brought down Queen Elizabeth's anger on both the contracting parties, who spent some time in the Fleet prison.

Meanwhile in 1596 and 1597 Southampton had accompanied Essex on his two expeditions to Cadiz and to the Azores, in the latter of which he distinguished himself by his daring tactics. In 1598 he had a brawl at court with Ambrose Willoughby, and later in the same year he attended Sir Robert Cecil on an embassy to Paris. In 1599 he went to Ireland with Essex, who made him general of his horse, but the queen insisted that the appointment should be cancelled, and Southampton returned to London. He was deeply involved in Essex's conspiracy against the queen, and in February 1601 was sentenced to death. Cecil obtained the com-

mutation of the penalty to imprisonment for life.

On the accession of James I. Southampton resumed his place at court and received numerous honours from the new king. On the eve of the abortive rebellion of Essex he had induced the players at the Globe theatre to revive *Richard II.*, and on his release from prison in 1603 he resumed his connection with the stage In 1603 he entertained Queen Anne with a performance of *Love's Labour's Lost* by Burbage and his company, to which Shakespeare belonged, at Southampton House.

Southampton was an active member of the Virginia company's council. He seems to have been a born fighter, and engaged in more than one serious quarrel at court, being imprisoned for a short time in 1603. He was in more serious disgrace in 1621 for his determined opposition to Buckingham. He was a volunteer on the Protestant side in Germany in 1614, and in 1617 he proposed to fit out an expedition against the Barbary pirates In 1624 he and his elder son enrolled themselves as volunteers for the United Provinces of the Netherlands against Spain. Immediately on landing they were attacked with fever, to which both succumbed, the father surviving, Nov. 10, 1624.

There exist numerous portraits of Southampton, in which he is depicted with dark auburn hair and blue eyes, compatible with Shakespeare's description of a "man right fair" Sir John Beaumont (1583–1627) wrote a well-known elegy in his praise, and Gervase Markham wrote of him in a tract entitled *Honour in his Perfection* (1624).

For further information *see* "Memoirs of Henry Wriothesley, the third Earl of Southampton," in Boswell's *Shakespeare* (1821), xx. 427 *sqq*, where many of the elegies on Southampton are printed

SOUTHAMPTON, Thomas Wriothesley, 1st Earl of (1505–1550), obtained extensive lands between Southampton and Winchester at the dissolution of the monasteries. He was made one of the king's principal secretaries in 1540, was knighted in the same year, and was created Baron Wriothesley of Titchfield in 1544 Having been lord keeper of the privy seal for a few months, he became lord high chancellor in 1544, in which capacity he became notorious by his proceedings against Anne Askew He was one of the executors of Henry VIII's will, and was created earl of Southampton in Feb. 1547 However, he had committed an offence in appointing four persons to relieve him of his duties as lord chancellor and he was deprived of his office in March, when he left privy council. Again in the council, Southampton helped to arrange the fall of Somerset. He died on July 30, 1550.

For the career of the 1st earl *see* Lord Campbell, *Lives of the Lord Chancellors;* E. Foss, *Judges of England.*

SOUTHAMPTON, Hampshire, England, 79 m. S.W. of London by the S.R. The town stands near the head of Southampton Water, an inlet of the English Channel which forms the estuary of the river Test; on a peninsula bounded east by the river Itchen. The county borough includes, since 1920, South Stoneham, part of North Stoneham, Swaythling, Bitterne, Sholing, Itchen and Woolston, and Weston and Newtown, giving a total area of 9,192 ac and a population (1921) of 160,994.

There was a Roman settlement on the east bank of the Itchen. It was walled, and inscribed stones, coins, pottery, etc., have been found. Southampton (*Hantune, Suhampton*) superseded the Saxon *Hantune* and was a royal borough before 1086. The charter was given by Henry VI. in 1445, while by charter of 1447 the neighbouring district was absorbed. A charter was finally given by Charles I. in 1640. Southampton has returned two members to parliament since 1295. There are remains of the old Norman walls, strengthened by towers at intervals, such as the Arundel Tower at the north-western corner. The site of the castle, near the water, is built over. It was originally a Saxon fortress, and was partly demolished in 1650.

One old house, known as King John's Palace, is considered to be earlier than any example of the 12th century in England. The South and West town gates date from the early 14th century, while Bar Gate, as it stands, is later, and retains excellent Decorated work. Blue Anchor Gate also survives. Numerous early vaults remain below the houses within the walls. The two old churches, St. Michael's, the central tower and lofty spire of which rise from Norman arches, and Holy Rood, partly Decorated, are greatly modernized. St. Michael's contains a Norman font of black marble The chapel of St Julian is of transitional Norman architecture, greatly altered by restoration It was originally attached to the hospital of God's House, founded in the time of Henry III for eight poor persons, the existing buildings of which are modern The chapel was allocated as a place of worship by Queen Elizabeth to certain Protestant Walloon refugees. The priory of St. Denys, an Augustinian foundation of 1124, gives its name to a suburb by the Itchen, and has left only fragmentary ruins Netley Abbey (*q v*) 3 m S E is a ruined Cistercian abbey

The Gildhall, used as a court-house, is in the upper part of Bar Gate. The Tudor House is a well preserved relic, now corporation property and used as a museum The Edward VI grammar school was founded in 1550 and reorganized in 1875, and occupies modern buildings Alderman Taunton's trade school was founded in 1752, and includes a technical department. The University College of Southampton, formerly housed in the Hartley Institution, removed to new buildings at Highfield in 1914

The Port and Its Trade.—Southampton was the chief port of Winchester. It had a large import and export trade, and in the 13th century was the second wine port in England Wool was very largely exported, and the fact that it was brought to this port to be shipped probably extended the woollen trade in the west of England The rise of London as a port, the prohibition of the export of wool, the loss of the Winchester market after the suppression of the monasteries, and the withdrawal of the court led to a gradual decline of trade in the 16th century.

The modern importance of the port begins with the creation of a pier and harbour commission in 1803, and the erection of the Royal Victoria Pier in 1831. The prosperity of the town was enhanced by the opening of railway communication with London in 1840. The harbour is one of the finest natural harbours in the kingdom, and has the advantage of a double tide, the tide of the English channel giving it high water first by way of the Solent and two hours later by way of Spithead In 1892 the docks, which lie at the southern end of the peninsula, became the property of the Southern Railway Company, then the London & South-Western The present docks include the Empress open dock (18½ ac) with a depth of 26 ft. at low water. The quays on the rivers Itchen and Test have been extended to 4,492 ft and 4,220 ft. respectively The depth at these quays is 28 ft. and 32 ft. respectively (low water). There are the Outer (16 ac) and Inner (10 ac) docks. The total extent of quays and jetties after the extension power of 1925 is approximately 21,214 feet Besides this there is the Prince of Wales graving dock, the Trafalgar graving dock, a large floating dock some 960 ft long and four other dry docks. The west station has been rebuilt with a view to giving further railway traffic facilities Southampton has an air service which operates from Woolston aerodrome to the Channel Islands. The Woolston area has large shipbuilding and engineering works Southampton is the chief port for express transatlantic passenger services, notably those of the Cunard, White Star and Canadian Pacific lines, while the West African, West Indian, South American, South African, Peninsular and Oriental, and Australian and New Zealand services also use this port, as do a number of cross-channel services under the control of the Southern Railway.

Southampton gives name to a suffragan bishopric in the diocese of Winchester The county borough was created in 1888.

SOUTHAMPTON, a township of Long Island, New York. Pop. (1925) 15,393 (State census). It embraces several villages, including Southampton (pop. 3,952 in 1925), Quogue, West Hampton and Eastport, and is a summer resort, with many fine estates and clubs. Potatoes are grown in large quantities. Southampton was settled in 1640, from Lynn (Mass.). It became an important whaling centre, and in 1678 Governor Andros mentioned it as one of the principal trading ports of the Colony The Shinnecock Indians long took part in the whaling industry, and many of them were lost in the wreck of the "Circassian" here on Dec. 31, 1876 The village of Southampton was incorporated in 1894.

SOUTH AUSTRALIA, a state of the Commonwealth of Australia, occupying 380,070 sq miles (12·78%) in the central

southern portion of the continent. Its southern boundary is the coast-line whose absolute length (1,540 m.) somewhat belies its geographical significance.

Physiography.—Situated athwart the junction line of the great western plateau and the great central plains of Australia, and having also special features of its own, South Australia falls into a number of different physical areas though its relief is nowhere so marked as that of the eastern States and there is relatively little land above 2,000 ft. (a) The north-west quarter is occupied by the south-western extension of the western plateau. (b) The north-eastern quarter is occupied by the Lake Eyre depression, with its horseshoe of mud and marsh-filled depressions ("Lakes" Frome, Callabonna, Blanche, Gregory, Eyre [3,700 sq. miles], Torrens) surrounding the northern Flinders Ranges. (c) Southwards from these lies an area where recent (Pliocene) cross-patterned warping and faulting, elevation and submergence have provided the most decisive features of the State:—Mount Lofty–Flinders Range, the northern part of Yorke Peninsula, the Spencer Gulf–Lake Torrens (semi-drowned) valley; the Flinders–Barrier spur or ridge, the extremities of the peninsulas, Kangaroo Island and perhaps also—though it is older—the Gawler Range. (d) South and east of this lies the Murray and south-eastern lowland plain, the western fringe of the great Murray (Tertiary sea-basin) lowland and the counterpart of the Lake Eyre basin in the north.

The coasts are alternately rocky and cliff-bound (*e.g.,* Bight, Jervis Peninsula) and again low, sandy and backed by dunes. Their general inhospitality is due partly to uplift in relatively recent geological times. Most distinguished is the granite coast from Cape Jervis to Port Elliot, and most curious the long "haff" of the Coorong. (*See* further: AUSTRALIA: *Geomorphology, Soils, Drainage.*) The Murray has some 500 miles of its lower course in South Australia. Its total fall in South Australia is only 57 ft. and its outflow to the sea, through Lake Alexandrina (*q.v.*) and over a sandy bar, is meagre.

The north-eastern corner of the State (118,000 sq. miles) forms part of the Great Artesian Basin, the water-bearing beds lying at (average) depths of 4,000–5,000 ft. in the north-east but shallowing until, along the edge of the W. Australian platform, the waters well up in a line of remarkable "mound-springs." The soft strata of the Lower Murray basin also yield plentiful supplies, often of good quality, from depths of 50–350 ft. and, towards the extreme south-east (Penola–Millicent) the underground water-table intersects the surface and has resulted in extensive swamps and coastal lagoons. Boring westwards of Oodnadatta has revealed good supplies and the results of recent prospecting in the vast western interior (northwards from the transcontinental railway line) are reported to have been encouraging. The yield of the north-east bores is, however, diminishing: one well 5,458 ft. deep yields now only 50 gallons a day.

Climate.—South Australia lies wholly within the temperate zone but the greater part of the north lies in that "No Man's Land" between northern and southern rainfall and shares the aridity or erratic régime of the continent's interior. Av. ann. temps. range from *c.* 70° F in the north-east to *c.* 56° in the extreme south, but much greater extremes are experienced in the north and in the interior generally than in the coastal parts especially towards the south-east. So with rainfall. Apart from occasional descents of northern (monsoonal) summer rains into the north and north centre of the State, the rain falls in winter and is heaviest (20–25 in.) and most reliable over the central south and south-east coastal areas. Inland (northwards) the average amounts rapidly die away and practically all the areas north of lat. 31° 50′ S.—and in the east, north of the River Murray—have less than 10 in., and the extreme interior has only *c.* 5 in. (Oodnadatta, 4·97 in.) and this extremely erratic. The wettest portions are in the extreme south-east (25–30 in.) and in southern Eyre's Peninsula; the central highlands and, to a less extent, Spencer Gulf, induce heavier precipitation and cause a long tongue of higher rainfall (20–25 in. in the S., with 40 in. in the hills east of Adelaide, to 15–10 in. in the N.) to extend far into the interior. (*See* also PORT AUGUSTA; ADELAIDE; and *inf.*)

Population, Settlement and General Economic Development.—Comparatively long settled, possessing a climate mainly temperate, with little of the sensational in her development, South Australia shows few unusual features as regards population. With an area 12·78% of that of the Commonwealth, the population (1927–28) of 575,800 represents 9·27% of that of the Commonwealth's total, nearly 57% (327,700) being metropolitan. The increase, if not at a very high rate, has been remarkably steady (1920–27: 1·66–2·68%), and due to natural causes and to immigration in about equal proportions. The average density is low (1·49 per sq. mile) and this, as well as the distribution, exhibits clearly the effect of physical and also of historical circumstances. The overwhelming majority of the people live in the belt of highlands and coastal lowlands which stretch northwards from Encounter Bay and Jervis Peninsula to the lat. of Port Augusta and rather beyond. Yorke Peninsula and south-east Eyre's Peninsula, and the Murray River valley are comparatively well-peopled; the "South-East," parts of the "Mallee" country (south of the Murray) and the north-west coastal parts of Eyre's Peninsula have a fair but relatively isolated amount of settlement. The great interior, though partly pastoral, contains very few people.

Of the total area of the State only 7% has been alienated (1927–28), some 49% is held under lease and licence (42%, 259,300 sq. miles, under pastoral lease) and 44% is unoccupied. The total production (1926–27) was valued at £41,154,000 (£73 13s. per head) to which agriculture contributed *c.* £16,635,000; manufactures, £13,100,000; pastoral industry, £6,128,000; dairying, poultry, etc., £2,928,000; mining, £1,032,000 (1927: £1,189,000). Moreover, in 1921, 12·83% of the total population was classed as "industrial," 10·60% as "primary producers," 10·59% as engaged in transport and commerce. Discernible in these figures are: (a) The overwhelming importance of the "gulf" area—lowlands and highlands—containing the capital city (manufactures, commerce) with its surrounding agricultural and dairying districts, Port Pirie (*q.v.*) with its metallurgical industry and the largest continuous areas of agricultural production. (b) The relatively sparse population and secondary position of the northern areas with their pastoral industry. (c) The relative unimportance of mining.

In the northern areas—*i.e.,* the 280,000 sq. miles lying north of *c.* lat. 31° S. (*v. sup.*)—the chief geographical determinant is the climate with its high summer temperatures, large annual and diurnal range, and its small and very erratic rainfall (*v. sup.*). These lands are, and will probably long remain, pastoral areas, capable of improvement through water-conservation, pasture cultivation and control of rabbits and dingoes, but never perhaps of more than second or third rate quality. The western half is only now being slowly occupied. Recent reconnaissance and well-sinking seem to indicate wide-spread underground (shallow) water-supplies, and stock-routes (with wells) have been established from the Musgrave Range to the central railway line at Warrina (south of Oodnadatta) and from Coward, on the same line, south-west to Wilgena on the transcontinental line. The east (Lake Eyre Basin) is better known and more developed, and contains scattered cattle and sheep stations—besides a mission-station—with their artesian wells. These lie mainly along the lines of railway and the two other main stock-routes—(Marree–Diamantina River–Birdsville, and Hawker or Farina [on central railway]—Strzelecki Creek–south-west Queensland, respectively)—which branch north-north-west and north-north-east respectively from near the head of Flinders Range and serve to bring stock from as far as Central Australia and south-west Queensland to their markets in the south. Some 80,000–90,000 cattle and 890,000 sheep are carried normally—the latter mainly in the north-east—but the density per square mile is low.

The second division includes the central highlands and part of their eastern spur (the Flinders-Barrier Range "bridge"). But between these and the eastern boundary of the State lies a strip (lats. 30–34° S.) which might, not inappropriately, be termed the "Eastern Interior," since in respect of climate (large temperature range; rainfall under 10 in.) it more resembles the northern interior and is devoted almost exclusively to pastoral pursuits (cattle and sheep). The coastal zone is the best developed portion

of the State and comprises nearly all the mineral deposits so far worked, a large part of the agricultural, dairying and manufacturing areas and sites, besides the capital city and nearly all the larger towns and important parts of the State The *mineral* output is at present relatively small The copper areas, notably those of the Moonta-Kadina field, though they probably still contain valuable reserves, have virtually ceased production Their annual output (1916–20) alone averaged £600,000, whereas in 1927 the total copper production of the State was valued at £12,500 The iron-ore is practically inexhaustible; the Iron Knob area northwest of Spencer Gulf, at present vigorously exploited and the ore exported from Whyalla (1927. £831,000, *see* AUSTRALIA. *Minerals,* and *Metallurgy*) The State possesses perhaps upwards of 70,000,000 tons of available coal but much of this is of soft (sub-bituminous) and rather poor quality (high sulphur content) and unfavourably situated Valuable clays and building stones abound, and the salt and gypsum deposits are the largest and best in Australia, are easily worked and serve as a basis for industrial developments (alkali and chemical industry) Deposits of salt occur on Yorke Peninsula (Yorke Town, with port at Edithburgh), at Lake Macdonnell, near Fowler's Bay (Bight) (2,500,000 tons salt, gypsum, 70,000,000 tons), and near Port Wakefield The high temperatures (net evaporation. 30–80 in) and semi-enclosed (high-salinity) waters of the gulfs also facilitate salt-production by evaporation Some 18,000,000 tons of reserves of salt exist, the output (1927) was valued—salt. £178,400, gypsum £82,000

In the vegetation eucalypts predominate The Mallee scrub extends as far north as about the 12 in av ann rainfall line ("Goyder's Line" in South Australia), and serves roughly to differentiate the (potentially) agricultural lands from the pastoral (mulga, blue-bush, etc) areas of the interior "Mallee-country is wheat-country" is now almost a maxim, and the trees (roots and over-growth) yield useful fuel Several of the lower-growing eucalypts yield valuable essential oils (av ann output eucalyptus oil, 5,000–8,000 gal , yacka gum [picric acid] 500–1,500 tons, Kangaroo Island being important for both), and wattle (tanning) bark is also produced (5,000–8,000 tons)

Water-supply, under the existing climatic conditions, had early to be provided The highlands (including Eyre's Peninsula) form the main catchment areas and here some 18 reservoirs, having a total capacity of nearly 17,000,000,000 gallons serve an area of over 18,500 square miles, with 5,120 miles of mains In the Northern Interior agriculture is absent, in the extreme south it is of the Victorian type (*see* VICTORIA), on the Murray it is mainly by irrigation, here it is, on its extensive side, wheat—with some mixed (wheat-and-sheep)—farming and, in its more intensive aspects vine and fruit (including olive) culture, apiculture, poultry, etc There are (1927–28) 2 862,000 ac under wheat (*cf* New South Wales 2,990,000, Victoria 2,900,000; Western Australia 2,812,000 ac) and by far the greater portion of this lies, in the area under review, in Yorke Peninsula and in the lowlands and highlands east of the gulf Here the fairly reliable winter and spring rains, followed by a hot and dry summer, are ideal for early winter planting, and harvesting (December–January), and loam soils—lighter and more sandy in parts of Eyre's Peninsula—and the prevailingly flattish terrain permit of "extensive" farming methods and large harvests per unit manpower Usual farms average from 200 to 240 ac and, as elsewhere in Australia, superphosphates are largely used as fertilisers (91% of the total area cultivated in the State is manured, 147,000 tons of manure, that is to say, over 93 tons per acre, being used) and the producing areas are very dependent upon rail or port outlets The following figures illustrate the wheat-bearing capacity of the areas under review

	Fallowed		Unfallowed	
	Ac	Yield	Ac.	Yield
Central	450,444	15·25	61,617	8·45
Lower North	659,748	17 69	90,669	10 17
Upper North	189,467	13 05	34,720	5 42
Western	184,222	12·07	439,225	8 75

Barley and oats are grown in moister areas and poorer soils, and a considerable part of the wheat and oats sown is reaped as hay (500,000 ac in the whole State)

Dairying is carried on mainly on the plains and in the hills within reach of Adelaide where markets and export facilities exist, and the same applies to some extent to pig and poultry rearing, bacon-curing, etc Apart from dairy herds few cattle are now found in this area, but sheep, though not of first importance, are widely kept, often as an element in a mixed-farming régime, and bred (crosses) for both meat and wool

The southern region (Mount Lofty Range) is the home of vine, fruit, vegetable and, to a less extent, of olive culture Vines and olives thrive on the lower western slopes (below 500 ft) of the Adelaide hills, while further north-east and north the Angaston, Tanunda and Clare districts are noted for their excellent wines. (Olive oil production 1926–27 16,500 gallons) Oranges, lemons, peaches, apricots and almonds abound on the plains or in the valleys of the hills where water, shelter and warmth are available Northern fruits (apples, plums, pears, etc) also abound and the rich valley-bottoms (*e g* , Piccadilly and Uraidla) within a 20–30 mile radius of Adelaide produce and market much small fruit (strawberries, raspberries, currants, etc) and vegetables One of the striking features of Adelaide is the profusion of fruit and vegetables available, ranging from tropical (bananas, etc), through Mediterranean (including melons, etc) to temperate types A high standard of agricultural production has been achieved and is maintained by the work of agricultural colleges and research institutes (*e g* , at Roseworthy, and the Waite Institute, University of Adelaide) Such manufacturing as exists is concentrated mainly in the metropolitan area, more particularly in the outlying suburbs (*e g* , Hindmarsh, Kilkenny, Islington, etc), in ports Adelaide, Pirie, Wallaroo Many industries are carried on largely with imported fuel (coal) and even imported raw materials and owe their existence mainly to the tariff and the local market

Few inland settlements have as many as even 2,000 inhabitants (Peterborough, 3,000, Kadina, formerly a mining town, 2,500) The harbours are rarely good—Port Lincoln, a wheat port and naval station, is an exception—but the small ports are numerous Yorke Peninsula is notably devoid of railways, communication being maintained by coasting steamers and packet boats Port Adelaide alone has an outer harbour visited by ocean-going vessels Land routes within this area, apart from a fairly well-developed and growing system of roads, consist of railway lines Adelaide is an important railway centre from which the systems run, branching, mainly northwards—following the physiographic trend-lines—but also east, crossing the Mount Lofty range rather uneconomically at its highest part

By the River Murray Agreement, Lake Victoria (in New South Wales) was allotted to South Australia as a storage reservoir (514 000 acre-feet) as well as 9 weirs and locks to be constructed within the State. Of these the Lake Victoria works are virtually complete, 5 weirs are completed and 3 more are under construction (1928), one of the completed weirs operating to keep Lake Bonney (in South Australia) partly filled as a reservoir The water thus becoming available in the Lower Murray district is being applied partly to irrigation and partly to water-supply for general (farming) purposes in areas beyond the irrigation area Irrigation is generally by pumping, but, below Morgan, the flat strips and crescents of alluvium of the originally marshy trench-floor have been embanked and drained ("reclaimed lands") and here irrigation by gravity is possible Irrigation holdings are usually limited to 50 acre leases, but larger blocks of "dry" land are available Large quantities of sub-tropical fruits (including currants and raisins) are grown and exported (fresh, dried, preserved or pulped) Renmark is the oldest, largest and best-known settlement (total area 23 000 ac ; pop 4,800), and comprises large fruit-packing sheds, distilleries, etc , some of them managed co-operatively The reclaimed lands are used mainly for the production of fodders (lucerne, etc) and vegetables

The Mallee scrub lands, long regarded as a desert, are now large wheat producers Plentiful supplies of underground water

are available at 15–300 ft. depth, and the rainfall (10–15 in.) and light soils suffice to produce, under modern methods, fairly reliable crops of 10–15 bu. per acre. Clearing is an initial difficulty, and large areas (*e.g.*, in the Ninety Mile Desert) defy cultivation, and the rail-haul is long and expensive. But the areas thrive and progress. In 1926–27, 269,000 ac. (fallowed lands) were sown to wheat and yielded 13·1 bu. per acre; in addition, 352,000 ac. unfallowed (7·8 bu. per ac.) and mixed (sheep and wheat) farming is succeeding the pioneering wheat-growing. The newly-constructed railways spread a wide fan across the country, tap the Murray at Waikerie, Loxton, Renmark, etc., and the north-west Victorian "Mallee" by means of the Pinnaroo line. These lines converge at Tailem Bend, a growing centre on the river below Murray Bridge. Near by, at Moorlands (15 miles to the east), is a lignite deposit (8,250,000 tons), which assist the district.

Separated from the areas described by a large stretch of rather thin (limestone and occasional sandy) soils which form lightly timbered and rather poor pastoral country, the "south-east," with its richer patches of arable lands, is fairly self-contained, rather remote from Adelaide, and climatically (lower temperatures and heavier rainfall: 20–33 in.) more akin to south-west Victoria. The poorer country is devoted to cattle and sheep. Good agricultural lands exist (*e.g.*, around Narracoorte and elsewhere); Mount Gambier in particular has volcanic soils, and the Millicent area rich recently-drained swamp flats. Mixed farming including dairying, is carried on.

STATISTICAL REVIEW

Area, Population, etc.—*Area:* 380,070 sq. miles = 12·78% of area of Commonwealth, all within temperate zone; coast-line 1,540 miles. Population (estimated, Dec. 1927): 575,771 = 1·49 per sq. mile and *c.* 9·27% of population of Commonwealth. Metropolitan, 327,686 = 56·91% of total.

Production and Agriculture.—(1926–27): Total: £41,-154,000 = £72.13.0 per caput. Agricultural: £16,635,000; manufactures, £13,077,000; pastoral, £6,128,000; dairying, £1,882,000; poultry, £1,046,000; mining, £1,032,000. Agriculture (1926–27): *Area under cultivation:* 6,058,380 ac. Wheat, 2,768,500 ac.; barley, 256,530 ac.; oats, 152,180 ac.; hay, 496,000 ac., other fodders (lucerne, peas, etc.), 61,100 ac.; vineyards, 50,270 ac.; orchards, 31,500 ac.; fallow, 2,100,000 ac. Production: Wheat (1921–28): 22,000,000–35,559,000 bu. (7·69–14·29 bu. per ac.); barley: (av. (1920–27) *c.* 4,000,000 bu.; oats, *c.* 2,000,000 bu.; orchards, etc., apples: (av. last 5 yrs.): 674,000 bu.; oranges, 373,000 bu.; apricots, 246,000 bu. Vineyards (last 5 yrs.): wine, 11,830,000 gal.; currants, 105,700 cwt.; raisins, 121,450 cwt.

Dairying, Livestock.—Cows (1915–26): 130,000–140,000. Butter, 13–16,000,000 lb.; cheese, *c.* 3,500,000 lb.; bacon, 5,-400,000 lb. Poultry (1921–27): *c.* £1,060,000. Honey, *c.* 2,000,000 lb. Horses, *c.* 250,000; cattle, 350,000–400,000; sheep 6-7,000,-000; pigs, 60,000–90,000. Of the total sheep, 70% are comprised in flocks of up to 5,000 head, and 20·8% in flocks of 5,000–20,000 each. The clip averages 42–50,000,000 lb. (av. last 5 yr. 55,-656,000 lb.), fleeces averaging 8·2–8·5 lb. Total value of wool (last 5 yrs.): £4,878,000; (1927–28: £5,275,000).

Trade and Commerce.—Total (overseas): £32,500,000–£33,500,000. *Exports:* (1924–25—1926–27): £17,094,000–£19,-419,000 (wheat, barley, flour, £7,300,000–£8,800,000; wool, etc., £4–£5,000,000; minerals (including Broken Hill concentrates): £2,900,000–£5,200,000; hides, skins, etc.: £610,000–£800,000; wines, £92,000–£620,000; fruits, £400,000–£670,000; butter, £96,000–£171,000. Total exports to United Kingdom: (1925–26): 63·5%; (1926–27): 55·5%.

Imports: (1925–26—1926–27): £14,079,000–£15,510,000 (*c.* 56% from British countries), chiefly textiles, etc. (£2,600,000); motor vehicles (*c.* £2,000,000), fuel oils (£1,120,000), machinery and metal goods, *c.* £4,000,000.

Ports, Shipping, Railways, etc.—Total trade of Adelaide: £25–26,000,000; Port Pirie: £3,600,000–£5,600,000; Wallaroo: £1,700,000–£2,000,000; Port Lincoln: £610,000–£935,000. *Total Shipping:* (inwards: 1927): 1,444 vessels = 5,123,000 tons, of which *c.* 1,250 vessels (4,425,000 tons) are British.

Social.—Education: (1927), 1,028 schools (State primary and higher); 2,637 teachers, 86,500 pupils (average attendance: 73,-180); average cost: £10.3.2. Also 188 private schools with average attendance 14,175. University; income (1927): £98,300, with endowments £540,500. Technical Colleges, etc., average attendance: 10,400. Total (State) expenditure on education (1927): £1,-161,000 (£2.1.0 per caput of pop.), besides expenditure on public charities (hospitals, State wards, pensions, etc.).

Finance.—Public debt (1927): £88,540,152 (£155.1.9 per caput). Revenue: £10,784,897; expenditure: £11,834,947, of which £233,768 was set aside for public debt. Savings Banks: (1927) depositors, 512,332, deposited £23,600,897 (£41.6.10 per caput of pop.), *c.* 90% of the total population being depositors. Including deposits in banks of issue the total sum on deposit in banks (all types) was £50,424,077 (£88 per caput of pop.).

See A. Grenfell Price, *South Australians and their Environment*, and various official South Australian publications.

HISTORY

Though the coast of the Northern Territory was well known to Portuguese and Spanish navigators as early as perhaps 1530, being called Great Java, it was not surveyed till 1644, when Tasman laid down the line of shore pretty accurately. The western part of the southern coast had been seen and named Nuyt's Land in 1627. But Flinders, by his discovery of the two great gulfs, Kangaroo island and Encounter bay, in 1802, was the first to reveal South Australia proper. Captain Sturt descended the Murray in 1830, and looked over the hills near Adelaide. The first to direct attention to a settlement there was Major Baron who communicated with the Colonial Office in Feb. 1831. His suggestion was to establish, at no charge to the British Government, a private company, that should settle a party on Yorke peninsula. After much discussion South Australia was by Letters Patent made a British province in 1836. It was arranged that a local government should be established when the settlement had 50,000 people. Though the first settlers were sent to Kangaroo island, all were afterwards gathered on the Adelaide plains. The colony was proclaimed under a gum tree on Dec. 28, 1836. Great delay took place in the survey of land. The South Australian Company purchased large tracts from the commissioners at 12s. per acre and sold at 20s. A general speculative spirit arrested progress. Governor Gawler went into extravagant outlay on public buildings, etc., and drew against orders upon the English Treasury. Such difficulties arose that the British rulers had to suspend the charter in 1841 and create South Australia a Crown colony. A revival of prosperity took place when the farms were tilled and poverty had taught prudence. Copper and lead mines were subsequently discovered. Kapunda in 1843, and the Burra Burra copper mine in 1845, greatly aided in the restoration of commercial credit. The gold fever in Victoria drew off numbers in 1852; but the good prices then realized for bread-stuffs gave a great impetus to farming.

A partially elective legislative council was established in 1851 and in 1856 the colony was given its own Constitution and self government. From its origin as the venture of private enterprise the State has passed through orderly stages of evolution up to the zenith of democratic government. Such alterations as have been made in the Constitution have been in the direction of a still further enlargement of the franchise. Payment of members proved to be the corollary of manhood suffrage. In 1887 a temporary act was passed for the payment of £200 a year to each member of both houses, and in 1890, the law was made permanent. Thus was rendered possible the direct representation of all classes. Soon afterwards the parliamentary Labour party came into existence. In 1894 the principle of "one man one vote" was extended to that of "one adult one vote" by the inclusion of women as voters on terms of absolute equality with men. The delegates to the Federal convention and to the Commonwealth parliament were in South Australia elected by the combined vote of men and women. Elections were formerly held in successive batches, but since 1893 they have taken place simultaneously in all districts. Electoral expenses are rigidly limited, both as to objects and

amount Although there is no general statute the referendum has often been applied The salary of members was increased to £400 annually in 1921. (*See* AUSTRALIA.)

SOUTH BEND, a city and the county-seat of St Joseph county, Indiana, U S A., at the head of navigation and on the southern bend (hence the name) of the St Joseph river of Michigan, and (by rail) 86 m E. by S of Chicago Pop (1920) 70,983 (19% foreign-born white), estimated locally in 1928 at 102,000 The city has an area of 16·58 sq m, an altitude of 726 ft, and an assessed valuation (1927) of $190,781,410 It is served by the Grank Trunk, the Lake Shore & Michigan Southern, the Michigan Central, the New Jersey, Indiana & Illinois, the Chicago, Indiana & Southern, and the Vandalia railways, and by four inter-urban electric lines Among the principal buildings are the city-hall, the county court-house, the public library, and the Oliver Hotel In Notre Dame, a suburb, are St Mary's College and Academy (Roman Catholic, chartered 1855) for girls, and the university of Notre Dame du Lac (Roman Catholic, first opened in 1842, and chartered in 1844) In 1910 the university had 87 instructors, 1,005 students, and a library of 60,000 volumes It is the headquarters of the order of the Holy Cross, whose sisters have charge of St Mary's College and Academy. South Bend ranked fourth among the manufacturing cities of the state in 1905 Its industrial establishments include carriage and wagon works (those of the Studebaker Bros Manufacturing Company being the largest in the world), plough and agricultural machine works—the Oliver Chilled Plow Works, founded by James Oliver (1823–1909), being particularly well known—the wood-working department of the Singer Sewing Machine Company, iron and steel foundries, flour-mills, and paper and pulp mills. The water-supply is obtained from 122 artesian wells, with a daily capacity of about 24,000,000 gallons South Bend was the site of an Indian village and of a French trading post It was settled about 1820, laid out about 1831 (when it became the county-seat of St Joseph county), incorporated as a village in 1835, and chartered as a city in 1865

SOUTHBRIDGE, a town of Massachusetts, U S A, on the Quinabaug river. Pop (1920) 14,245 (29% foreign-born white), 15,489 in 1925 (State census) The river falls 165 ft at this point, furnishing abundant water-power Optical goods are its most distinctive product In 1801 a poll parish (popularly called Honest Town) was formed from parts of Charlton, Dudley and Sturbridge; and in 1816 it was incorporated

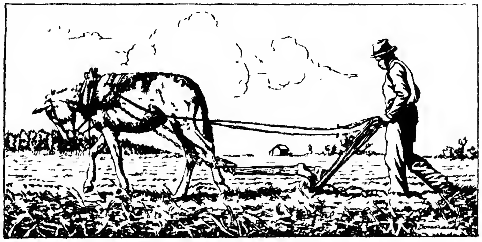
SOUTH BROWNSVILLE, a borough of Pennsylvania, U S A, on the Monongahela river, adjoining Brownsville and opposite West Brownsville The three boroughs form one community Pop (1920) of South Brownsville 5,675, of Brownsville, 2,502, of West Brownsville, 1,902, 1928 local estimate of the combined population, 12,000

SOUTH CAROLINA, popularly called the "Palmetto State," is an Atlantic coast State of America, and one of the original Thirteen Its area is 30,989 sq m, of which 494 sq m are water

Physical Features.—South Carolina is mainly in the coastal plain and Piedmont plateau regions, but in the north-west it extends slightly into the Appalachian mountain region Locally the coastal plain region is known as the low country, and the Piedmont plateau and Appalachian mountain regions are known as the up-country The coast is low and islands increase in size and number toward the Georgia border For about 10 m inland the coastal plain is occupied largely by salt marshes Then, although continuing flat, the surface rises at the rate of about 2½ ft per mile for 40 m or more

Parts of the Blue Ridge rise abruptly from the foothills to 3,413 ft in Mt Pinnacle, 3,218 ft in Caesar's Head, and 3,157 ft in Table Rock The highest point in the State is Sassafras mountain (3,548 ft) in the Blue Ridge and on the North Carolina State line The mean elevation of the State is about 350 feet

The principal rivers rise in the Appalachian mountains and flow south-east into the Atlantic ocean In the middle section, Santee river is formed by the confluence of the Wateree (known above Camden as the Catawba) and the Congaree, which is in turn formed by the Broad and the Saluda The basin of this system embraces about half the area of the State In the north-east the Great Pedee and its tributaries—the Little Pedee, Waccamaw and Lynches—are wholly within the coastal plain, but the main stream is a continuation below the fall line of the Yadkin river, which rises in the mountains of North Carolina The Edisto is the principal stream in the south-east In the Piedmont plateau there are



A "ONE-MULE" FARMER WORKING HIS FARM IN SOUTH CAROLINA

rapids, but in the coastal plain the current becomes sluggish, and in times of high water the rivers spread over wide areas

Flora.—Palmettos are confined to the coast For some distance from the ocean there are magnolias, live oaks draped with long grey moss and reed-covered marshes In the swamps are cypress, gum and bay trees In most of the uplands of the coastal plain the long-leaf pine is predominant, but large water-oaks and under-growths of several other oaks and of hickories are not uncommon On the Piedmont plateau and in some of the more hilly sections below the fall line there is some short-leaf pine, but most of the trees in these areas are hardwoods Deciduous oaks are most common, but beech, birch, ash, maple, black walnut, chestnut, sycamore and yellow poplar also abound On the mountains are oaks, chestnut, laurel, white pine and hemlock Among indigenous trees, shrubs and vines are the blackberry, grape, persimmon, plum, crab-apple, hickory, chestnut and hazel nut

Climate.—Along the coast the climate is mild and equable At Charleston, the mean winter temperature is 51°, the mean summer temperature 80°, the mean annual temperature 66° and the range of extremes from 104° to 7° For the State the mean temperature is about 63° In nearly all sections January is the coldest month and July the warmest Aiken, near Augusta, Ga has a very mild winter season and is a popular resort The mean annual rainfall for the State is about 47 75 in and its distribution is excellent Seventeen inches fall during the summer Snow is uncommon in the south-east but elsewhere there may be several inches The frost-free season ranges from 245 days on the coast to 204 days on the uplands Tornadoes occur in the west and the coast suffers from hurricanes

Soils.—In general the soils of the Piedmont plateau are such as have been formed by the disintegration of the underlying rocks These consist mostly of granite and gneiss, but in the north-central section there is trap-rock, and in the south-east section some slate On the Piedmont plateau the subsoil is a reddish or yellowish clay In the upper section of the coastal plain the soil is for the most part a loose sand, but lower down it becomes more fertile

Population.—The population of South Carolina was 249 073 in 1790; 502,741 in 1820, 594,398 in 1840, 703 708 in 1860, 705 606 in 1870, 995,577 in 1880, 1,151,149 in 1890, 1 340,316 in 1900, 1,515,400 in 1910, 1,683,724 in 1920, an increase of 11 1% in the last decade, as compared with 13 1% and 16 4% in two preceding decades The population on July 1, 1928 was estimated by the U S Census Bureau at 1 864 000 In only one other State Mississippi, in 1920, did the negroes exceed the whites; in South Carolina 51 4% of the total, or 864,719 were negroes, and 48 6% were whites There has been a steady decline in the percentage of negroes from the high point of 60 7% in 1880, until in 1928 the Census Bureau estimated them at a little less than 50% The increase of negro population during the decade 1910–20 was only 3·3% as compared with 20 5% for the whites In 1920 of the

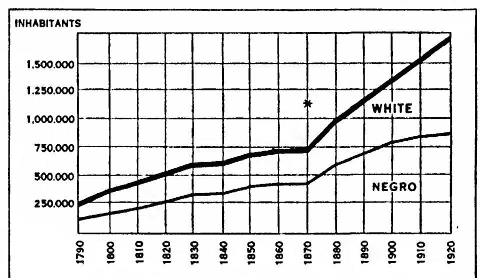
total population 99·2% were native-born. Density of population was 55·2 per square mile. The urban population was 17·5% of the whole, as compared with 14·8% in 1910.

Government.—South Carolina was governed from 1670 to 1719 under the provincial charter of 1665, from 1719 to 1775 under commissions and instructions from the Crown, and from 1776 under the Constitutions of 1776, 1778, 1790, 1865 and 1895. An amendment to the Constitution may be proposed in either house of the legislature. If approved by two-thirds of the members elected to each it must be submitted to the people at the next election for members of the house of representatives. If it is approved by a majority of those voting upon it and subsequently by a majority vote in each house of the general assembly chosen at that election, it becomes a part of the Constitution. A convention to revise the Constitution may be called by a two-thirds vote in each house ratified by a majority of those voting for representatives at the next election.

A voter must be 21 years old, a resident of the State two years, of the county one year, of the voting precinct four months and must obtain a certificate of registration conditioned on showing that he or she is able to read and write the Constitution or the past year paid taxes on property assessed at $300 or more. (Assessments are usually at about one-fourth value.) Illiterates were allowed before 1898 to register for life by "understanding" the Constitution. Paupers, idiots, the insane, prisoners and persons ever convicted of certain crimes, unless pardoned, are disfranchised. As the democratic nomination is equivalent to election, more important is the rule confining voting in the party primary to white Democrats and a negligible number of negroes who can prove by ten white men that they have voted Democratic from 1876, the only other qualifications being those of citizenship, age and residence as stated in the Constitution.

Constitutional amendments changed the terms of the governor and other State officers from two to four years, beginning with those elected in 1926. The governor is ineligible for re-election. He may veto "any one or more of the items or sections contained in any bill," but may be overruled by a two-thirds majority of those voting in each house. In practice the item veto has been used only regarding appropriation bills. The general assembly, meeting annually, is composed of the senate (one member from each of the 46 counties elected for four years) and the house of representatives (124 members elected for two years from the counties in proportion to population). The State elects seven congressmen.

The five supreme court judges and the 14 circuit court judges are elected by the legislature for ten and four years respectively.



GRAPH SHOWING GROWTH OF POPULATION IN SOUTH CAROLINA. 1790–1920 (*1870 CENSUS GENERALLY DEFICIENT IN THE SOUTHERN STATES)

Magistrates (justices of the peace) are appointed by the governor with senate confirmation, although the recommendation of the senator from the county or of a primary election practically determines the selection. In a few counties a county court with an elected judge disposes of a large part of the lesser civil and criminal cases elsewhere burdening the circuit courts. The probate judge in each county (elected) has also the duties of a juvenile court. The State is divided into two Federal court districts.

Local Government.—The unit of local government is the county. Counties are divided into townships, but there are no township governments, the township being hardly employed except for the assessment of taxes and the care of local roads. Although the forms of municipal government are prescribed under general statutes and enjoy certain constitutional rights, they are considerably subject to State legislative authority. They may exempt new manufactories from taxes for five years, except for school purposes, provided a majority in a popular election approve.

The county is administered by a commission, almost always popularly elected. Road or hospital commissions, etc., are frequently appointed by the governor, usually on recommendation of the county legislative delegation. The usual county officers are elected, except the auditor and treasurer, who are appointed by the governor with senate confirmation; however, the governor practically always names the successful primary election candidates without question. There being no county legislature, the State legislature is oppressed with a mass of local legislation. It enacts usually without question whatever the senator and representatives of the county concerned agree upon. These thus form in effect a county legislature. The senator, as controlling action by the senate, thus exercises an enormous extra-legal power.

Miscellaneous Laws.—Any officer negligently permitting a prisoner to be lynched forfeits his office and becomes ineligible to any office unless pardoned. The county, without regard to the conduct of the officers, is liable in damages of not under $2,000 to the heirs of the deceased. Since 1895 divorce has been constitutionally forbidden. The few divorces ever granted in South Carolina were under the act of 1872 permitting divorce for adultery or wilful desertion for two years.

Finances.—The State tax commission, created 1915, supervises all tax administration and directly administers the income, inheritance, gross receipts, public utilities, corporation and gasolene taxes. More than three-fourths of the revenues supporting the State Government are from these special taxes, less than one-fourth being from the general property tax. There thus exists in practice to a considerable degree separation of State and local revenues, the latter being derived from the general property tax, and in the case of municipalities from business licences in addition. The gasolene tax and motor vehicle licence fees are divided between State-maintained roads and local roads. Schools are assisted by the receipts of a small capitation tax.

Education.—As early as 1710 public school education was provided for indigent children. The present free-school system was established in 1868. The educational system is under the supervision of the State superintendent of education, with the assistance of a board composed of the governor, the superintendent of education and seven other persons appointed by the governor. State support and regulation of high schools were greatly increased in 1907. In 1925 there were 285 State-accredited public high schools. South Carolina maintains a dual school system: one for white and one for coloured children. The public school enrôlment in 1927–28 for whites was 248,272 and for negroes 228,003; the number of white teachers was 8,687 and of coloured, 4,451. The average length of session was 171 days for white and 115 days for coloured schools. Other improvements are night schools for adults, enlarged facilities for agricultural, vocational and home economics training, State standard certification of teachers and more effective State supervision. By the 1919 law four months' school attendance is compulsory, but enforcement is lax.

Agriculture.—The products of the soil equal less than half the output of the factories. The value of the 19 principal crops in 1927 (not including truck) was $155,300,000 as against $317,741,669 for all manufactures, the value of the crops being a little above, and that of manufactures appreciably below, the average for the past six years.

The total acreage in farms in 1925 was 10,638,900, or 54·5% of the total area of the State; in 1920 the acreage was 12,426,675, or 63·7% of the total area. The number of farms showed a corresponding decrease; the total in 1920 was 192,693 as compared with 172,767 in 1925. Of the 172,767 farmers in South Carolina,

82,186 were whites and 90,581 were coloured White owners were 41,601, coloured, 18,368, white tenants, 40,251; coloured 72,179, white managers 334, coloured 34 The percentage of tenancy was 65 1 The total farm acreage (10,638,900) in 1925 was divided as follows. crop lands, 5,035,956, pasture land, 1,637,431; woodland, 2,562,000, all other land in farms, 1,403,507. The average acreage per farm was 61 6, but crops were harvested from only 25 ac per farm. The valuation of all farm property was $523,084,383; of the average farm, $3,028 The average per acre value of land alone was $32 62 The farm population decreased during the five years, 1920–25, from 1,074,693 to 911,885, or a total loss of 15%

Cotton holds the first place in acreage, with about 50%, corn (maize) the second, with around 30% The State has two great cash crops—cotton and tobacco, five grain crops—corn, wheat, oats, rye, rice; four legumes that yield both hay and grain, cowpeas, soy beans, velvet beans, peanuts; two for syrup, sorghum and sugar cane Potatoes, both white and sweet, fruit and vegetables also add to the wealth of the State

The principal crops with their approximate acreage, product and value as of Dec 1927 were as follows —

Crop	Acreage	Product	Value
Cotton	2,421,000	735,000 bales	$72,030,000
Cotton seed		148,000 tons	9,004,000
Indian corn	1,407,000	25,410,000 bu	22,904,000
Wheat	80,000	880,000 ,,	1,338,000
Oats	448,000	10,327,000 ,,	7,745,000
White potatoes	29,000	3,034,000 ,,	5,765,000
Sweet potatoes	53,000	5,300,000 ,,	4,240,000
Hay	446,000	358,000 tons	6,436,000
Tobacco	104,000	75,020,000 lb	15,564,000
Peaches		615,000 bu	922,000

The coastal region, with a mild climate and a soil responding quickly to intensive cultivation, is especially suited to commercial truck farming The chief products, exclusive of potatoes and cane grown for syrup, are watermelons, cabbages, cucumbers, snap beans, spinach, asparagus, tomatoes and lettuce Strawberries, dewberries, blackberries, figs and grapes add to the fruit wealth of the State

Dairying and the live stock industry as a whole, in South Carolina, is capable of much further development The State produces only about one-third of the creamery butter it consumes, there being, it is estimated, less than one milch cow to the farm, upon the average The total value of all dairy products in 1924 was $5 852,427 The total value of live stock on the farms of South Carolina on Jan 1, 1928 was estimated at $38,299,000

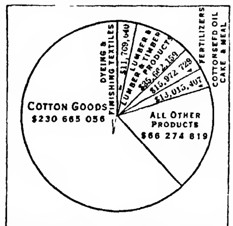
Forests.—The total stand of saw timber in South Carolina in 1920 was estimated at 25 000,000,000 bd ft, of which 15,000,000,000 bd ft were in softwoods and 10 000,000,000 bd ft in hardwoods The annual growth was estimated at about 250,000,000 bd feet The 520 sawmills operating within the State in 1925 produced 2 7% of the total lumber production of the United States Small quantities of turpentine and rosin are produced from the slash pine forests of the coastal plain

Fisheries.—The commercial fisheries are located in the five coastal counties—Beaufort, Colleton, Charleston, Georgetown and Horry Approximately 30,000,000 oz of oysters were canned in 1927 and the quantity is increasing Chief among other products are shad, mullet, sea bass, sturgeon, shrimp and hard clams

Minerals.—South Carolina's mining output is small, amounting in 1925 to only 07% of the total mineral value of the United States. The principal mineral products in the order of value were clay products, stone, sand and gravel and barite

The stone quarried in South Carolina is chiefly granite and granite-gneiss High grade granite, the "Winnsboro Blue," is quarried in Fairfield county near Rion. Barite is mined chiefly near Gaffney, Cherokee county.

Manufactures.—The manufactures of South Carolina showed a remarkable development during the first quarter of the 20th century In 1927 the capital invested was $316,115,480, the value of the products $317,741,669, and the average number of wage-earners 104,201 The manufacture of cotton goods is much the most important, its output constituting in value in 1925 61 8% of the State's manufactured products The number of cotton manufacturing establishments in 1927 was 223, the number of producing spindles 5,408,713, looms 127,061, the operatives 79,772, the amount of raw cotton consumed 1,253,112 bales and the value of the output $234,251,698 Practically every grade of cotton cloth is produced Factors contributing to the phenomenal development of the cotton textile industry in South Carolina are the abundance of cheap hydro-electric power from the Piedmont streams, a suitable climate and dependable native labour The Piedmont section leads in the textile industry The values of the output in the chief producing counties were, in 1927, for Spartanburg $39,560,544, for Greenville $33,419,033, for Anderson $22,679,697, for York $15 341,131, for Greenwood $14,945,723, for Union $13,724,135 and for Chester $10,522,567 Charleston and Richland counties are important for diversified manufactures



GRAPH SHOWING LEADING MANUFACTURES OF SOUTH CAROLINA, 1925, ON BASIS OF VALUE OF PRODUCTS

During 1927 lumber and timber products equalled $15,962,747, cotton seed oil, meal and cake, $11,769,999 electric current, $11,690,293, fertilizers $8,809,816 (temporarily greatly reduced), foundry and machine-shop products $4,668,674, printing and publishing $3,483 623, flour, feed and grist $3 135,179

Hydro-electric development has greatly aided both industrially and in bettering living conditions The report of the U S Geological Survey (1926) ranks South Carolina sixth among the States of the Union in developed water-power and estimates the State's potential water-power at 632 000 h p, while private estimates go as high as 1,000 000 The existing 58 water-power plants have a capacity of 514 428 horse-power In 1927 63% of the power used by textile mills was hydro-electric The Murray dam 10 m above Columbia on Saluda river, to be completed in 1930, 208 ft high and 7,000 ft long (one of the largest earth dams in existence), will form a lake 50,000 ac in area and develop 200,000 h p (150 000 kilowatts)

Transportation and Commerce.—The chief railway systems of South Carolina are the Southern, the Atlantic Coast Line, and the Seaboard Air Line Steam railway mileage, Jan 1, 1928, was 3,693, of which 365 m were double tracked Also, electric interurban lines operated 134 miles An extension of the Georgia & Florida railway from Augusta, Ga, to Greenwood S C, 56 m is under construction The mileage of State highway, Jan 1, 1929, was 5 809, of which 1,047 m were paved and 8 m were surfaced with bitumen and crushed stone About 227 000 motor vehicles were registered in 1928

Inland water communication is possible on a number of the larger navigable rivers, but is undeveloped except slightly near the coast Charleston in 1925 had a foreign trade of 1,142,114 tons valued at $42 893,403, and a coastwise trade of 1 531 577 tons valued at $113 239,039 Georgetown had a coastwise trade of 122,400 tons valued at $3,390,883

HISTORY

The history of South Carolina may be divided into the periods of discovery and exploration (1521–1663), proprietary rule (1663–1719); royal rule (1720–75), and Statehood (from 1776) The first Europeans to visit the coast were a party of Spaniards from Cuba in 1521 The first settlement was made by Spaniards under Ayllon in 1526, but, after a few months it was abandoned The Spaniards again settling in 1566, maintained a port on Parris island for about 20 years In the meantime (1562) French Protestants under Jean Ribaut made an unsuccessful attempt to establish a colony on Parris island (*see* PORT ROYAL) In 1629 Charles I granted to his attorney general, Sir Robert Heath, all the territory lying between the 31st and the 36th parallels and

extending through from sea to sea, but no settlement was made, and in 1663 the same territory was granted to the earl of Clarendon (1609–74), and seven other favourites of Charles II. A second charter in 1665 extended the limits to 29° and 36° 30′. The proprietors were to legislate for the Province "by and with the advice, assent and approbation of the freemen." They were empowered, though not required, to grant religious freedom to dissenters. Circulars were issued in 1663 and 1665 offering most liberal terms to prospective colonists. In the Fundamental Constitutions adopted by the proprietary board in 1669, John Locke and Lord Ashley (1621–83) prepared for the Province an elaborate feudal system of government which would have been obsolete even in Europe. Little effort was made to enforce the more impractical portions of the Constitutions. They were, nevertheless, an element in rousing the feeling of discontent among the colonists which culminated in the overthrow of proprietary rule, and they encouraged the large plantation system which constituted the foundation of the slave-holding aristocracy.

First Permanent Settlement.—The first permanent English settlement was made in April 1670 at Albemarle Point, on the west bank of the Ashley river, but as the situation proved unfavourable the government and most of the people moved over in 1680 to the neck between the Ashley and the Cooper rivers, the site of the present city of Charleston. The area of settlement was gradually extended along the coast in both directions, but did not penetrate far into the interior. There were many English from Barbados and French Protestants, who influenced the history of the Province.

Struggles for Popular Control.—Her political history during the colonial era is the story of a struggle between popular and prerogative interests, first between the people and the lords proprietors, later between the people and the Crown. From 1670 to 1700 the principal questions at issue were the refusal of the settlers to subscribe to the numerous editions of the Fundamental Constitutions and disputes over the collection of quit-rents. Concessions were finally made which brought the Government more directly under popular control. In 1693 the commons house, elected by the people, secured the privilege of initiating legislation. The truce was followed by a controversy between churchmen and dissenters. A test act requiring members of the assembly to conform to the Church of England and to take the sacrament of the Eucharist according to the rites and usages of that church (1704) was defeated only through the intervention of the Whig House of Lords in England. By an act of Nov. 30, 1706, which remained in force until 1778, the Church of England was made the established religion. After a few years of peace and prosperity, the proprietors, acting on the advice of Chief Justice Nicholas Trott (1663–1740), adopted a reactionary policy, vetoed several popular laws and could not give aid in the desperate 1715 Indian war. In 1719 the people rebelled, overthrew the existing government and elected their leader James Moore as governor. The result of the revolution was accepted in England, and the province at once came under royal control, although the rights of the proprietors were not extinguished by purchase until 1729. Theoretically South Carolina and North Carolina constituted a single province, but, as the settlements were far apart, their governments were always separate. Until 1691 each had its own governors. From 1691 to 1712 there was usually a governor at Charleston and a deputy for the northern settlements, and after 1712 there were again separate governors. The first attempt to define the boundary was made in 1730, but the work was not completed until 1815.

The period 1725–75 was a period of great prosperity, based upon the trade in pelts (mainly deer skins) and more permanently on the rapidly expanding rice and indigo culture. The southern colonies' Indian trade centred mainly in Charleston. This, and a rich agriculture and the large commercial business to serve them, supplied the economic basis of a coast country society of notable intelligence and culture. One of the earliest theatres in America, musical culture, libraries, and the education of a large number of youths in England, gave the society around Charleston a tone and finish at that time rare in the New World.

Passing under the royal Government did not check the encroachments upon the governor and council by the commons house of assembly, which defiantly announced the powers of the British Commons as its model. By 1760 the council had almost ceased to exercise any real control over legislation. They rarely initiated or amended a bill, and never attempted to change a money bill without incurring violent denunciation from the popular house and sometimes paralyzing legislative action for years.

Movements Toward Independence.—The State was preparing for independence. Although the measures of the British Government after 1763 were not especially oppressive to the province, the people were too long accustomed to having their own way, and had, especially in the bitter dispute over the Wilkes fund (1769–75) involving the right of the commons alone to control finance, developed too fully a sense of general American and even British freedom to submit to measures which they regarded as subversive of the principles of liberty. Delegates were sent to the Stamp Act Congress (1765) and to the Continental Congresses (1774 and 1775). A council of safety appointed by an extra-legal provincial congress virtually took over the Government in June, 1775. Royal administration ended when, Sept. 15, the governor dissolved the assembly and fled.

Wars with the Spanish in 1686, 1702–04, 1740, with the Spanish and French in 1706, with pirates in 1718, with the Yemassee Indians in 1715 and the Cherokees in 1760–61, with aid only in 1760–61 from British troops, and a slave rising in 1739 had accustomed the people to arms. The State suffered severely during the Revolution both from British troops and from the presence of numerous loyalists. A British fleet attempting to capture Charleston was repulsed by Ft. Moultrie, June 28, 1776. Calm prevailed until Clinton returned in 1780 with an overwhelming force and Gen. Benjamin Lincoln surrendered the city, May 12.

Completely overrun, there followed two years of fighting involving more battles, though most of them small, than occurred in any other State. A Continental army under Gen. Greene assisted by State troops under Sumter, Marion and Pickens slowly drove the British back into Charleston and wrecked the plan of British troops from the South to join those from the North to crush Washington. The chief battles fought in the State were Ft. Moultrie (June 28, 1776), the siege of Charleston (March 12–May 12, 1780), Camden (Aug. 16, 1780), King's Mountain (Oct. 7, 1780), Cowpens (Jan. 17, 1781), Hobkirk's Hill (April 25, 1781) and Eutaw Springs (Sept. 8, 1781).

The generation following the Revolution witnessed an ambitious programme of transportation development. The Santee canal, connecting Charleston with the whole Santee-Wateree-Broad-Saluda river system, was opened in 1800. Highway building followed. The latter was dropped and the canal was ruined from railroad development. The South Carolina railroad, 133 m. from Charleston to Hamburg opposite Augusta, when completed in 1833 was the longest railroad in the world.

Strife Between Sections.—The early State period was characterized by a bitter struggle between the older low country and the newer up country, the latter settled largely by Scotch-Irish coming down the Piedmont belt from Pennsylvania, Virginia and North Carolina. In 1786 it was necessary, to allay discontent, to consent to the removal of the capital to a newly located site to be called Columbia. Although removal took place in 1790, State officers until 1865 kept offices both in Columbia and Charleston and the supreme court met in each city to hear appeals from the two sections respectively. The up country (then comprising a larger area than now thus designated), containing four-fifths of the white population and one-fifth of the wealth, in 1808, with the help of a liberal low country minority led by Joseph Alston, secured a constitutional amendment apportioning one senator to each county and representatives to each county in proportion equally to white population and wealth. This left the control of the upper house to the low country and that of the lower house to the up country. Manhood suffrage followed in 1810. The low country's fear for its slave interests was allayed as slavery, fostered by cotton culture, spread up the State.

The South Carolina college was chartered in 1801 largely to

allay sectional enmity. Only the necessity of standing unitedly against anti-slavery and reconstruction agitation from the North prevented the more numerous element from forcing its democratic changes until late in the 19th century

Nullification and Secession.—Northern anti-slavery agitation and the adoption of a tariff harmful to Southern agriculture united both factions in the passage of the Ordinance of Nullification, Nov. 24, 1832, forbidding the execution of the tariff in South Carolina. The readiness of a powerful minority to assist President Jackson, combined with a reduction of the tariff, operated to deter the majority from forcing the issue to armed conflict, but left a bitterness within the State that disappeared only after 1850 in the face of graver danger from outside

Following the slave conspiracy of 1822 and the Northern abolitionism the slave code was severely revised (1840–44), even to forbidding the sending of a slave to freedom anywhere in the world The years 1850–52 saw most of the people deterred from secession only from lack of the co-operation of other States. After 1828 Virginia's Southern leadership was superseded by the more uncompromising leadership of South Carolina under John C Calhoun South Carolina was the first State to secede, her ordinance of Dec. 20, 1860, being almost unanimously approved by her citizens With a white population of 291,300, the State put into the field 62,838 effectives, with a total enrolment, including reserves, of 71,083, of whom 22% were killed or died in prison Gen. W. T. Sherman's march across the State, February to March 1865, was accompanied by enormous destruction, including the burning of Columbia

Reconstruction.—The misfortunes of war were more easily borne than the humiliation of reconstruction Under President Johnson's guidance, the white population elected officers, who were soon ejected under the Congressional plan of reconstruction, disfranchising most whites and transferring power to the negroes, Northern adventurers ("carpetbaggers") and disreputable native whites ("scallawags") In the spring of 1868 the State was "re-admitted" to the Union under the control of these elements, and entered upon a period of eight years of crime and corruption, accompanied by arrogance on the part of the blacks that the whites found unendurable Legislation was by bribery. Stealing extended from large blocks of State property to the price of a politician's whiskey Two hundred trial justices were said to be unable to read Daniel H Chamberlain, able carpetbagger and would-be reformer of his own party (governor 1874–76) declared in 1901 that if he had been re-elected in 1876, his party, even with white assistance, could not have given government "fit to be endured." The most urgent pleas on a non-partisan basis failing to draw the least sympathy in Washington, the whites in 1876, by combined fraud, intimidation and persuasion of negroes elected Gen Wade Hampton (1818–1902) governor by a narrow majority President Hayes's withdrawal of troops in March 1877 marked the collapse of "radical" rule

Political Parties.—Since 1876 practically the entire white population has been Democratic, partly from historical reasons and partly because of the conviction that union under the only national party that has defended them against negro rule in the past is necessary for the maintenance of white supremacy The only murmuring in this connection was in 1928, when the nomination of Governor Alfred E Smith for president put a severe strain on the party loyalty of thousands of South Carolina Democrats, though few voted against him

The Reform Movement.—In 1878–80, under the leadership of M W Gary (1831–81), the old conflict between up and low country became a fight mainly between the poorer masses and the propertied classes

The triumph under Benjamin R. Tillman (governor 1890–94; U S. Senator 1895 to his death in 1918), prominent "farmers' movement" leader, was facilitated by acute agricultural distress Col. A C. Haskell's appeal to the negro against Tillman, with proviso that there should be only white officials, was generally condemned even by his own class, drew practically no negroes, and only served to embitter feeling among the whites The farmers', or more broadly "reform," movement was marked by the establishment of Clemson Agricultural and Mechanical college (1889), the dispensary system of State liquor monopoly (abandoned because of corruption and failure to restrain intemperance) and the work of the Constitutional Convention of 1895 disfranchising so far as possible the negro Direct primary elections, long in use in most of the counties, beginning in some in 1878, were adopted in 1896 for naming U S Senators, Congressmen and State officers State politics since 1890 present a strange combination of rancorous personal politics, mass conservatism and dislike for "aristocratic" influence Class feeling was strongly manifested in the campaigns of Coleman L Blease (governor 1911–15). Factionalism subsiding, Blease was in 1924 elected Senator after having been badly defeated in 1918 on a platform condemning American participation in the World War The State contributed over 70,000 men to the World War

Agriculture and banking suffered severely in the deflation of 1920–22 Recovery has been made through more diversified and scientific farming and the expansion of manufacturing

Bibliography—M Tuomey, *Report on the Geology of South Carolina* (1848), *South Carolina*, a handbook prepared by State dept of agriculture, commerce and industries and Clemson college (1927), R M Harper, *Regional Geography of South Carolina, Illustrated by Census Statistics* (1920), *Fourteenth U S. Census*, and other Census Bureau publications, A S Salley, Jr, ed, *Commissions and Instructions from the Lords Proprietors of Carolina to Public Officials of South Carolina, 1685–1715* (1916); *Publications* of State Historical Commission, and *Annual Reports* of various State officials, departments and commissions, D D Wallace, *Civil Government of South Carolina* (1922), and *South Carolina Constitution of 1895* (Univ of South Carolina Bulletin, 1927) Valuable bibliographies are E D English, *Author List of Caroliniana in University of South Carolina Library* (Univ of South Carolina Bulletin 1923), and "List of References on Reconstruction in S C" being *Select List of References No 457* of Library of Congress General histories are Y Snowden, ed, *History of South Carolina* (1920), W G. Simms, *History of South Carolina*, edit by M C S. Oliphant (1918), and E. C McCants, *History, Stories and Legends of South Carolina* (1927), the two last named being elementary texts. Useful for early period are *North Carolina Colonial Records* (1886–90), B R Carroll, *Historical Collections of South Carolina* (1836), *South Carolina Historical Society Collections*, vol v being the *Shaftsbury Papers* (1857–97); and the *South Carolina Historical and Genealogical Magazine*, published by the same society The standard works for the colonial period are E McCrady, *History of South Carolina under the Proprietary Government* (1897) and *History of South Carolina under the Royal Government* (1899) Older histories are A Hewatt, *Historical Account of the Rise and Progress of the Colonies of South Carolina and Georgia* (1779), D. Ramsay, *History of South Carolina* (1809), vol. 1 being little more than a reprint of Hewatt; Wm J Rivers, *Sketch of the History of South Carolina to the Close of the Proprietary Government* (1856), based on public documents; and W R Smith, *South Carolina as a Royal Province* (1903), also based on official manuscripts, D. D. Wallace, *Life of Henry Laurens* (1915), covers many phases of economic, social and political history from 1725 to 1791; B Mitchell, *William Gregg, Factory Master of the Old South* (1928) The standard work on the American Revolution is E McCrady, *History of South Carolina in the Revolution* (1901–02) The best treatment of the controversy between up and low country is Wm A Schaper, "Sectionalism and Representation in South Carolina," in the *Amer Hist. Assoc. Report* (1901) R Mills, *Statistics of South Carolina* (1826), gives varied information on each county. His *Atlas of South Carolina* is still the standard authority Monographs covering the past hundred years are: D. F Houston, *Critical Study of Nullification in South Carolina* (1896); C S. Boucher, *The Nullification Controversy in South Carolina* (1916), H M Henry, *Police Control of the Slave in South Carolina* (1914), P. M Hamer, *Secession Movement in South Carolina 1847–52* (1918); J. G Van Deusen, *Economic Bases of Disunion in South Carolina* (1928), J S Pike, *The Prostrate State, or South Carolina under Negro Government* (1874), J S Reynolds, *Reconstruction in South Carolina 1865–77* (1905), the standard work; W Allen, *Governor Chamberlain's Administration in South Carolina* (1888), well documented, H T Thompson, *Ousting the Carpetbagger* (1926), brief, F P Simkins, *The Tillman Movement in South Carolina* (1926) "Correspondence of John C Calhoun," Annual Report of the Amer Hist Asso, II (1899), is invaluable for 1804 to 1850 Valuable for literary and educational history are C Meriwether, *History of Higher Education in South Carolina* (1889) and G A Wauchope, *Literary South Carolina* (1923). (D D W)

SOUTHCOTT, JOANNA (1750–1814), English religious fanatic, was born at Gittisham in Devonshire Her father was a farmer and she herself was for a considerable time a domestic servant. She was originally a Methodist, but about 1792, becoming persuaded that she possessed supernatural gifts, she

wrote and dictated prophecies in rhyme, and then announced herself as the woman spoken of in Rev. xii. Coming to London at the request of William Sharp (1749–1824), the engraver, she began to "seal" the 144,000 elect at a charge varying from twelve shillings to a guinea. When over sixty she affirmed that she would be delivered of Shiloh on Oct. 19, 1814, but Shiloh failed to appear, and it was given out that she was in a trance. She died of brain disease on the 29th of the same month. Her followers are said to have numbered over 100,000, and are not yet extinct. She left a locked box with instructions for it to be opened by all the bishops together assembled at a time of national crisis. The box was finally opened in 1928 in the presence of one of the bishops, but it was found to contain nothing of interest at all.

Among her sixty publications, all equally incoherent in thought and grammar, may be mentioned: *Strange Effects of Faith* (1801–1802), *Free Exposition of the Bible* (1804), *The Book of Wonders* (1813–1814), and *Prophecies announcing the Birth of the Prince of Peace* (1814). A lady named Essam left large sums of money for printing the *Sacred Writings of Joanna Southcott*.

See D. Roberts, *Observations on the Divine Mission of Joanna Southcott* (1807); R. Reece, *Correct Statement of the Circumstances attending the Death of Joanna Southcott* (1815).

SOUTH DAKOTA, the "Sunshine State," is one of the North Central States of the American Union. It is rectangular in shape with an average length (east-west) of 380 m. and an average width (north-south) of about 200 miles.

Its area is 77,615 sq.m., of which 747 sq.m. are water surface. South Dakota formed the southern half of the original Dakota Territory, organized in 1861 and named after the Dakota Indians which inhabited the land. The Territory was divided into North Dakota and South Dakota by the enabling act of Feb. 22, 1889.

Physiography.—With the exception of the Black Hills district in the south-west, the State is a broad, wide rolling plain,

ROCK NEEDLES ON STATE HIGHWAY, BLACK HILLS, SOUTH DAKOTA

ranging from level river valleys in the east to irregular plateaux broken by buttes and scored by cañons in the west.

In the extreme north-east there is a range of low hills known as the Coteau des Prairies, which crosses the State in a south-south-east direction, forming the divide between the headwaters of the Minnesota river on the east and the James river on the west. The greater part of the James river valley lies in the bed of the extinct Lake Dakota, which was once a very narrow body of water. West of the James river valley lies an elevated table-land, known as the Coteau du Missouri, which marks the water-parting between the James and the Missouri rivers.

The Bad Lands.—In the south-west extreme results of erosion are seen in an accentuated form in the region between the White river and the South Fork of the Cheyenne river, known as the Bad Lands or *terres mauvaises*. This area extends from the 101st meridian up the White river for about 120 m. and varies in width from 30 to 50 miles. The most prominent features of the landscape rise from 150 to 300 ft. above the valleys; the latter and the flat tops of the mesas are sometimes covered with a scanty soil and a sparse growth of grass. The Bad Lands of the White river are noted for their wealth of animal fossils.

The Black Hills.—North-west of the Bad Lands of the White river lie the Black Hills (*q.v.*), an irregular dome-shaped uplift, about 125 m. long and 60 m. wide, lying partly in Wyoming, and with the main axis trending almost north-west and south-east. The main mass of limestone and crystalline rocks have in general a height of 4,000 or 5,000 ft. above the sea—some ridges and peaks rise higher. Cathedral park in the southern portion, Spearfish cañon in the north and the extensive fossil forest at the foot of Mattie's peak are noteworthy; while the Crystal cave, near Piedmont, and the Wind cave, near Hot Springs, are famous.

Drainage.—With the exception of the extreme north-east, the State lies within the drainage system of the Missouri, with its tributaries the Big Sioux, the James, the Grand, Moreau or Owl, Cheyenne and White rivers.

The Minnesota river has its source in the north-east, and the Big Stone lake, a body of water about 25 m. long and 3 m. wide, forms a connecting link between its headwaters and the rest of the stream. North of this lake lies Lake Traverse, 27 m. long and 3 m. wide, whose waters flow north into the Bois de Sioux river, whence they flow into the Red river (of the North). The portion of South Dakota east of the Missouri river is dotted with numerous shallow lakes, ranging from small ponds to bodies of water from 10 to 15 m. in diameter.

Forests.—The total woodland area has been estimated at 2,500 sq.m., about 3·25% of the land area, and of this amount 2,000 sq.m. are in the Black hills district. All the higher lands of this area are covered by forests consisting mainly of yellow pine, but spruce, aspen, white birch, bur oak, box-elder, red cedar, white elm and cottonwood are among the other varieties found. In the more arid regions the sagebrush and cactus make their appearance. Harney national forest lying wholly within the State, and Custer and Black Hills national forests lying partly within the State, have an area in South Dakota of 1,064,357 ac.

Climate.—Owing to the northern latitude, comparatively high altitudes and the great distance from the ocean, there are great annual variations of temperature and a small amount of rainfall. The State is coldest in the north-east where the mean annual temperature averages 42° F and warmest in the region south of the Cheyenne and west of the Missouri river where the mean annual temperature is 48°. The crop-growing season ranges from 120 days along the northern border to 150 days in the south-east. The average annual rainfall ranges from 14 in. in the north-west to 30 in. in the south-east.

Government.—South Dakota is governed under its original Constitution, adopted in 1889, with frequent amendments.

The legislative power lies in the State legislature, consisting of a house of representatives and senate, except that the people have reserved to themselves the powers of initiative and referendum. South Dakota adopted these two methods of legislative procedure in 1898 and was the first State in the United States to do so. Petitions of but 5% of the qualified voters are sufficient to secure either of these privileges. The legislature in 1927 consisted of 42 senators and 103 representatives, all elected for terms of two years.

The executive department is headed by the governor, elected for two years. The governor's veto can be overridden by a two-thirds majority in each house, and does not extend to bills passed directly by the people through their use of the initiative or referendum. The governor's judicial power is represented in his right to remit fines and grant reprieves, commutations and pardons which the courts may have imposed.

The judicial powers are vested in a supreme court, circuit courts, county courts, justices of the peace and such other courts

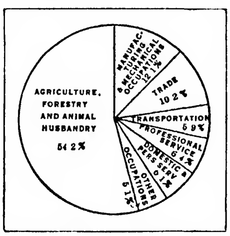
as may be created by law for cities and incorporated towns. The supreme court has appellate jurisdiction only, and two terms, at least, must be held yearly at the seat of government It consists of five judges chosen from districts by the qualified electors and serving terms of six years each The State is divided into districts or circuits in each of which is a circuit court with one or more circuit judges elected for a term of four years. The number of circuits can be increased by the legislature from time to time if deemed necessary There were in 1927 12 circuits and 21 judges. In each county is a county judge elected for a two year term

Population.—There were 636,547 inhabitants in South Dakota, according to the Federal census of 1920, an increase over the 583,888 in 1910 of 9% In 1925 the official State census registered a population of 681,000. In 1920 the white race represented 97·3% of the total population, the remainder being largely Indians, who numbered 16,384 There were only 832 negroes and but 142 Chinese The Indians are chiefly of the Dakota (or Sioux) tribes, the largest group being the Oglala Sioux at the Pine Ridge agency, which numbered 7,628 in 1925 There were also 5,700 Sioux at the Rosebud agency, 3,000 Cheyenne River Sioux near the mouth of the Moreau river, 2,500 at the Sisseton agency and 2,000 at Yankton, beside smaller bands at the Crow Creek, Lower Brule and Flandreau agencies.

A large portion of the pioneer settlers of South Dakota were foreign-born Since there has been little immigration since 1900, however, and the original pioneers are fast passing on by death, the percentage is rapidly decreasing Foreign-born numbered 175,865 in 1910, 82,391 in 1920 and 71,399 by the State census of 1925 In the latter year natives of Norway numbered 12,237, Sweden, 9,113 and Denmark, 5,395 Of equal importance, approximately, was the German element, there being 14,988 natives of Germany and 9,589 Russians, chiefly Teutonic Mennonites

In 1920 South Dakota averaged 8 3 inhabitants per square mile The most densely settled portion is in the south-east where some counties average over 25 persons per square mile East of the Missouri river towns are located every eight or ten miles along the railways and are so evenly spaced that few localities are more than 15 m. from a railroad town. South Dakota is largely an agricultural State and its high percentage of rural population (84% in 1920) is exceeded only in North Dakota and Mississippi among the States There are no cities larger than Sioux Falls, which had a population in 1925 of 30,127.

Education.—The public elementary and secondary school system is under the control of the superintendent of public instruction Under this official are three rural supervisors covering respective districts and a high school supervisor There were, in 1925–26, 5,430 elementary schools, of which 4,812 were located in rural districts, 502 in cities or villages The remaining 116 were of the consolidated type There were also 435 high schools of which 359 were properly accredited Of these 267 were giving the full four-year course There was an enrolment in the elementary schools of 138,166 and in high schools of 26,390. There were 7,106 elementary teachers with an average annual salary of $906 in rural districts, $1,114 in towns and villages and $1,053 in the consolidated schools There were 1,530 high school teachers employed at an average annual salary of $1,641.



OCCUPATIONS OF PERSONS TEN YEARS OF AGE AND OVER ENGAGED IN GAINFUL EMPLOYMENT, 1920

The State institutions of higher learning are controlled by the regents of education, five in number, appointed by the governor for terms of six years. Each institution is administered by its president. The University of South Dakota is located at Vermillion Its faculty in 1926–27 numbered 95 and its enrolment was 1,027. The university has charge of the geological and natural history survey of the State, of the State health laboratory and the State chemical laboratory. At Brookings the South Dakota college of Agriculture and Mechanic Arts is located, with an enrolment in 1926–27 of 848 and a teaching staff of 125 Preparatory work and vocational courses have been gradually dropped so that the institution can concentrate on work of college level The State School of Mines at Rapid City, in the Black Hills, enrolled 250 students in 1926–27 It issues numerous publications, among them *The Black Hills Engineer* There are several independent and denominational colleges, the most important being Dakota Wesleyan university, a Methodist institution at Mitchell (1926–27 enrolment 344, faculty 26), Huron college under Presbyterian auspices at Huron (1926–27 enrolment 311, faculty 31), Yankton college, a non-sectarian school at Yankton (1926–27 enrolment 300, faculty 33) and Sioux Falls, a Baptist institution at Sioux Falls (1926–27 enrolment 125, faculty 16) The Norwegian Lutherans support Augustana college, also at Sioux Falls

Charities and Corrections.—The State penitentiary situated at Sioux Falls had 463 inmates in July 1926 A printing department, farm garden and twine plant are operated, the latter making a net profit of $40,239 for the year 1925–26 The State hospital for the insane at Yankton had an average of 1,305 patients in 1925–26 A 1,750 ac farm is run and the labour of the patients themselves has financed the purchase of a vacationing park on the James river where a club-house has been erected for their use. At Redfield is the school and home for the feeble minded, an institution with 427 inmates in 1925 The State training school for delinquent boys and girls is at Plankinton and had an average of 131 pupils in 1925–26 A soldiers' home is maintained at Hot Springs, in the Black Hills, open to both soldiers and their wives

Finance.—The total wealth of South Dakota was estimated in 1922 to be $2,926,000,000 This amounted to $4,482 *per caput*, a higher average than in any other State of the United States For assessment purposes taxable property was valued by the board of equalization in 1926 at $1 805,466,033 Of this, $1,420,768,023 was classified as real property, represented by agricultural lands valued at $1,245,703,110, city real estate valued at $165 120,365 and mineral lands to the value of $9 944,548

For the year ending June 30, 1926 all revenue to the State Government amounted to $27,637,806, while its expenditures totalled $26,073,254 The largest items of expenditure, besides those of the general fund for administration purposes, were $4,984,267 for highways, $6,297,706 for rural credit purposes in aid of agriculture, $1,529,199 for hail insurance and $1,454,049 distributed to schools from the interest and income of the common school fund. The State in 1925 had a total debt of $62,100,000 and sinking fund assets of $45,527,000, leaving a gross debt of $17,405,000 or $25 65 *per caput* The purposes of the debt were divided into $48,400,000 for agricultural aid, $6,000,000 soldiers' bonus, $5,700,000 highways and $2,000,000 for improvements

There were, on June 30, 1926, 474 banks (108 of them national banks) with total resources and liabilities of $193,662,000 and capital, surplus and undivided profits of $18,987,000 Their deposits totalled $158,197,000, of which time deposits made up $85,570,000.

Agriculture and Livestock.—Agriculture is South Dakota's most important industry, and nearly 90% of its population are probably either directly engaged in it or engaged in industries directly dependent upon it Of the total population 361,779, or 51·1%, actually lived upon farms in 1925

The value of all crops fluctuates widely from year to year depending on crop conditions and prices In 1924, a good year in general, it was $245,606,000, in 1925, $187,344,000, and in 1926, an extremely poor year, $118,484,000 In 1919, when prices were high, the crop value was $311,007,000 In the depression following the World War the farming industry suffered most severely The depression is seen also in the drop in value of livestock on the farms, from $238,568,000 in 1920 to $146,222,000 in 1925, and in the decreased value of farm land from $2,231,423,000 to $1,201,015,000, or from an average of $64 42 to $37 51 per acre

In 1926 Indian corn was the leading crop, having a total value of $46,281,000, almost twice that of its nearest competitor, cultivated and wild hay combined As late as 1900 very little Indian corn was grown because only a few then existing varieties would

mature in most parts of the State, but the development of new varieties and acclimatization has made it now dependable in almost all sections. Its production is heaviest, however, in the south-eastern counties and decreases with the distance from the south-east corner. In 1923 the crop was 145,176,000 bushels. In 1926 there were 1,361,000 ac. of cultivated hay yielding 1,364,000 tons valued at $17,732,000 and 2,315,000 ac. of wild hay yielding 926,000 tons valued at $9,723,000.

Until recent years wheat was the largest money-producing crop of the State, and in good years it still rivals Indian corn for first place. In 1925 31,835,000 bu. valued at $40,734,000 were grown, but in 1926 a very poor crop resulted in but 10,840,000 bu. valued at $12,776,000. Wheat is relied upon more in the northern than in the southern part of the State. The oats crop valued at over $40,000,000 in 1924 decreased to $26,980,000 in the more nearly normal year of 1925. The barley crop was valued at $11,181,000 in 1925. Flax, another crop, extensively grown, especially upon new breaking, was valued at $8,552,000 in 1925. Potatoes, also very important, were grown to the value of $7,137,000 in 1925.

In the south-eastern part of South Dakota there is a large diversification of crops, and a great deal of intensive farming. These methods are spreading rapidly northward and westward over the entire State. Pigs and dairy cattle are being introduced in larger numbers, and a greater percentage of the grain is being fed to stock on the farms. Of 1,727,000 cattle in the State in Jan. 1927 (valued at $64,093,000) 534,000 were milch cows. Their value was $29,370,000. Creamery butter produced increased in value from $18,536,000 in 1918 to $29,193,000 in 1925. The number of swine increased from 1,010,000 in 1910 to 2,760,000 in 1925, in the latter year valued at $36,432,000. By Jan. 1927, they had decreased in number to 2,183,000 but increased in value to $37,111,000. They were most numerous in the south-eastern portion of the State. West of the Missouri, in the rougher country, there is a great deal of sheep-raising; the sheep grown increased in value from $3,042,000 in 1922 to $7,131,000 in 1927, when they numbered 721,000 head. Wool production in 1926 amounted to 4,712,000 lb., the average fleece being 8·1 pounds.

In 1920 69·4% of the farmers owned motor-cars, 5·7% owned motor trucks, and 59·4% were served by telephones, while 8·6% had gas or electric light in their houses. In 1925, 20·6% had tractors. The average size of a South Dakota farm decreased from 464·1 ac. in 1920 to 402·6 ac. in 1925.

Mining.—The bulk of the mineral output consists of gold and silver produced from the deep mines of the Black Hills, particularly from the famous Homestake mine in Lead City. Silver is a minor product and is only classed with gold because it is found in the same ores. Of the 1,674,720 tons treated in 1924 there was an average recovery of $3.65 in gold and $.05 in silver per ton, making the gold output $6,117,421 and the silver production $57,987. Together these metals contributed $6,175,408 of the $6,925,678 at which the total mineral output of South Dakota in 1924 was valued. In gold production South Dakota ranked fourth among the States. Altogether, the Homestake mine has produced over $200,000,000 worth of ore and paid $48,826,924 in dividends. During the World War, when there was a shortage of tungsten, South Dakota produced large quantities, totalling $1,106,740 in value for the years 1915–18 inclusive.

Manufactures.—The most important industries are those connected with the agricultural products of the State such as butter, cheese, condensed and evaporated milk ($13,325,741) and flour, feed and other grain-mill products ($3,219,709). Bread and bakery products amounted to $3,148,161 and lumber and timber products to $1,187,649. Except for concentration at Sioux Falls where products to the value of $36,166,431 were manufactured, factories were usually small and well distributed over the State.

Transportation.—There were in 1926, 3,841 m. of main line track in the railway systems of the State. Of these, the Chicago, Milwaukee, St. Paul and Pacific railway owned 1,636 m., including the only transcontinental line crossing South Dakota. The Chicago and North-Western railway has 1,119 m. of road in South Dakota.

Highways.—There were, in 1926, 116,906 m. of rural roads of which but 3,007 m. were surfaced. The State highway system included 5,924 m. of which 2,468 m. were surfaced. Expenditures upon the State highway system amounted to $5,596,000 in 1924 and $6,378,000 in 1925. Most of the important highways run from east to west. The Yellowstone trail roughly parallels the line of the Chicago, Milwaukee and St. Paul railway.

History.—It is possible that the Frenchman, Charles Le Sueur, visited South Dakota in the region around Sioux Falls as early as 1683 and that some trading with the Indians in that vicinity by French on the Minnesota river took place around 1700, but the first authentic exploration by white men, of which there is certain record, was that of the Verendrye brothers, who in 1743 came overland from the Assiniboine river in Manitoba to the Missouri in North Dakota, and wandered from there south-west probably to the Black Hills and thence east to the Missouri at the present site of Pierre. Theirs was a disappointed search for the "western ocean." In the decade of the 1780s fur traders began to enter South Dakota irregularly, coming up the Missouri river from St. Louis, down from Canada by the Red river of the north, or in from Wisconsin by the Minnesota river. In 1794 Jean Baptiste Truteau, leading a fur-trading expedition from St. Louis, caused the first building erected by white men to be built on the bank of the Missouri river, in Charles Mix county. Fur traders and trappers were, therefore, already familiar with the territory when the first scientific exploration party led by Lewis and Clark passed up the Missouri in 1804 on its way to the Rocky mountains. The whole area of the State in the meantime had been transferred from French to U.S. ownership by the Louisiana Purchase of 1803.

Following the Lewis and Clark expedition, which returned in 1806, the Missouri river became the natural highway for many expeditions trading with the upper Missouri Indians or passing westward to the mountains. Manuel Lisa, of St. Louis, ascended the river in 1807 and for many years thereafter either went himself, or sent parties to trade with the upper Indians. In 1817 Joseph La Framboise built old Ft. La Framboise near the modern site of Pierre, and around this post grew up the first settlement in South Dakota. In 1831 the first steamboat to ascend the Missouri reached the site of Pierre. It was owned and regularly used thereafter by the American Fur company, which by that time controlled the Missouri river fur trade. In 1832 Ft. Pierre was built for the same company. Except for a later period of bison-hunting, the fur trade period was about over in 1855 when the company sold this post to the U.S. Government.

Settlement.—The first attempt at permanent settlement by the agricultural pioneers was at the falls of the Sioux river in 1856 by a party from Minnesota. Other homes were established in the Sioux valley from 1857 to 1862, but all were abandoned because of fear of the Sioux Indians after the Minnesota outbreak of 1862. In the meantime, a permanent settlement was made at Yankton in 1859. In 1861 Dakota Territory was created by Congress and Yankton designated as its capital. Settlement was very slow at first, however, and even by 1870 when Iowa had 1,115,000 inhabitants, South Dakota had no more than 12,000. Sioux City, Ia., was reached by the railway in 1868 and in the same season stage lines to Yankton and Sioux Falls were established. The last two towns became the centres for early settlement in the eastern part of the State, and Sioux City was the depot and shipping point until the railway reached Yankton in 1873 and Sioux Falls in 1878.

In the meantime, a settlement of quite different character was developed in the Black Hills at the opposite end of the State. Gold was discovered in 1874 by the men of Custer's expedition,

and a rush of gold hunters followed But the region belonged to the Sioux Indians and the Government intervened to keep settlers out until an agreement could be made with the owners. Such an attempt was made at the Red Cloud agency in 1875, but when the Indians refused to cede the region, Government opposition to settlement ceased Between Nov 1875 and March, 1876 over 1,100 persons arrived in the hills, most of them stopping at Custer, the scene of the original discovery, which by March was a city of at least 6,000 persons The rapid exhaustion of the placers there encouraged prospecting elsewhere with the result of rich workings being discovered in Deadwood gulch, 75 m further north, in June 1876 Almost the entire population rushed to the new diggings where the city of Deadwood rapidly became famous The discovery of permanent bodies of ore gave it stability, and smaller towns grew up in outlying gulches In the autumn of 1876 Moses Manuel located the Homestake lode, which has supplied one of the world's greatest gold mines with a steady stream of ore to the present day Around it the city of Lead has grown up. Stage lines to Deadwood were established from Laramie, Wyo, Sidney, Neb and Bismarck, N D, and population grew rapidly

The "Dakota Boom."—During the years 1879–86 much of the territory of South Dakota was settled and these years are known as the years of the "Great Dakota Boom" At the end of the period all but three of the present day counties had settlements located in them, and all of the counties now east of the Missouri river had been organized In 1878 there was but 60 m of railway in the Territory, but by 1886 over 1,000 m of railway were built and settlement rapidly followed each railway.

During the energetic decade ending June 30, 1889, nearly 42,000,000 ac, or almost half the area of South Dakota, were homesteaded In 1887 no free land remained in 22 counties of southern Dakota Territory The population had increased from 98,268 in 1880 to 263,411 in 1885, and in 1890 it was 328,808 The boom times were brought to an end chiefly by crop failures, the terrible drought of 1889 producing widespread destitution

Admission to Statehood.—The boom resulted in a movement for statehood There was much agitation among the inhabitants for a separation of Dakota Territory into a northern and southern State, and this was made part of the programme of the National Republican Party in 1888 When the party prevailed in the subsequent election, North and South Dakota were admitted as separate States (Nov 2, 1889). From 1889 to 1897 South Dakota suffered a period of repeated droughts, the rainfall over large parts of the State being deficient every year Immigration was almost at a standstill and many homesteaders left the State Many counties in 1897, most of them west of the James river, had but half the population they boasted in 1887 Those that went were largely of American stock, the foreign immigrants being more persistent Commencing about 1896 the rainfall increased and fairly satisfactory conditions prevailed until 1910 These were years of stabilization and increasing prosperity, the aggregate value of farm property rising at least 500% between 1895 and 1910 The increase in population in the same years was 252,913 or 76%, a large proportion of the increase being west of the James valley Many of the Indian reservations were opened to settlement in the latter part of this decade

The years 1910–12 were unusually dry During the World War, values were inflated far beyond normal, only to be depressed alarmingly after the Armistice

South Dakota is normally Republican in politics and this party controlled the State Government from 1900 to 1926 In 1926 the State elected its first Democratic governor

BIBLIOGRAPHY —The recent publications of the various State departments and reports of officials must be consulted for authoritative information upon governmental activities The *South Dakota Manual*, published annually by the Public Printing Bureau contains many facts The bulletins, circulars and reports of the South Dakota Geological and Natural History Survey, also the bulletin of the South Dakota School of Mines contain many valuable studies of the minerals and natural resources. *Bulletin* No 11 of the South Dakota School of Mines (1917) is an exhaustive "Bibliography of the Geology and Mining Interests of the Black Hills Region." The School of Mines also publishes the *Black Hills Engineer* (1912 *seq*) For agriculture consult the reports and bulletins of the South Dakota agricultural experiment station and the Publications of the South Dakota Department of Immigration The most important books are S S Visher, *Geography of South Dakota* (1918), D Robinson, *History of South Dakota* (1904) and *Encyclopaedia of South Dakota* (1925), G W Kingsbury, *History of Dakota Territory* (1915), F. E Peterson, *Historical Atlas of South Dakota* (1904), G. F Will, *Archaeology of the Missouri Valley* (1924), O W Coursey, *Who's Who in South Dakota* (1916–25), L K Fox, *Who's Who Among South Dakotans* (1924–25), Peter Rosen, *Pa-ha-sa-pah, or, The Black Hills of South Dakota*, A D Tallent, *The Black Hills* (1923) *See* also the *Collections of the South Dakota Historical Society* (1902–26)

SOUTHEND-ON-SEA, a watering-place in Essex, England Pop (1921) 106,070 It was visited by Queen Caroline in 1804, and is the nearest seaside resort to London The bathing is good, but the tide recedes rapidly for nearly a mile The pier, which is over 1¼ m in length, permits the approach of steamers at all tides Westcliff-on-Sea is a western suburb Westward again is Leigh-on-Sea (pop 3,667), its lofty Perpendicular church tower is visible from afar The castle was built in the 13th century, and two ruined towers remain Southend was incorporated as a county borough in 1914

SOUTHERNE, THOMAS (1660–1746), English dramatist, was born at Oxmantown, near Dublin, in 1660, and entered Trinity College in 1676 Two years later he was entered at the Middle Temple, London His first play, *The Persian Prince, or the Loyal Brother* (1682), contained a flattering portrait of James II as the "loyal brother" The poet received a commission in Princess Anne's regiment, but his military career came to an end at the Revolution His two most successful plays were *The Fatal Marriage, or the Innocent Adultery* (1694), known later as *Isabella, or the Fatal Marriage*, and *Oroonoko*, or *The Royal Slave* (1696), the plot in each case being taken from a novel by Aphra Behn He died on May 22, 1746

His other plays are *The Disappointment, or the Mother in Fashion* (1684), founded in part on the *Curioso Impertinente* in Don Quixote, *Sir Anthony Love* (1691), *The Wives' Excuse, or Cuckolds make themselves* (1692), *The Maid's Last Prayer, or Any, rather than fail* (1692), *The Fate of Capua* (1700), *The Spartan Dame* (1719), taken from Plutarch's Life of Aegis, and *Money the Mistress* (1729)

See *Plays written by Thomas Southerne, with an Account of the Life and Writings of the Author* (1774)

SOUTHERN PACIFIC COMPANY, an American transportation system, comprising, with its affiliated companies, 17,000 m of rail lines and 3,800 m of water lines It serves directly a large part of the United States west of the Mississippi river (at New Orleans) through to the Pacific coast, besides steamships plying between New York city and the ports of New Orleans, Galveston and Houston Its lines also extend into Mexico as far south as Guadalajara

Construction of its first unit, the Central Pacific main line, completed in 1869, was the link from California across the Sierra Nevada mountains to Ogden, Utah, now 782 m from San Francisco, which completed the first through rail line between the eastern and western shores of the North American continent In 1883 the Sunset route was opened for traffic between New Orleans and San Francisco via El Paso and Los Angeles, distance 2,479 miles In 1887 the Shasta route was completed, giving a rail line between San Francisco and Portland, Ore, distance 771 miles Southern Pacific is also part of the Golden State route from Los Angeles to Chicago, its line, Los Angeles to Tucumcari, N M, 1,146 m, being one-half the distance to Chicago

The construction of the Central Pacific, followed by the Southern Pacific and the merged operation of both, was under the inspiration of four citizens of Sacramento Leland Stanford, Collis P Huntington, Mark Hopkins and Charles Crocker Stanford, prior to his death, founded and endowed Stanford university After the death of these men E H Harriman secured control and carried to conclusion projects previously planned, including the straight and level 104 m line from Lucin to Ogden, of which 31½ m were built across Great Salt Lake

The invested assets of the Southern Pacific Company exceed $2,125,000,000, its capital shares of $372,400,000 par value are owned by 58,000 stockholders Its equipment for handling traffic consists of 2,600 locomotives, 4,000 passenger cars, 87,000 freight cars, 23 ocean steamships and 24 ferry steamboats; it also has

half ownership in 40,000 refrigerator cars. (W. SPR.)

SOUTHERN RAILWAY, an English railway system. It was formed by the amalgamation of the London and South Western, London Brighton and South Coast, South Eastern, and London, Chatham and Dover Railway Companies, together with the South Eastern and Chatham Railways Managing Committee and various subsidiary companies, under the Railways Act, 1921. Operation as a single concern was commenced Jan. 1, 1923, with a total mileage of 2,156. Seventy-five per cent of its traffic is passenger, its suburban business being enormous and most concentrated. It operates 700 miles of electrified track.

The Southern Railway controls eight routes to the Continent, including the most popular cross-channel service via Dover-Calais and during the year 1927 over two million passengers were conveyed across the English Channel by these routes. The company's modern fleet of passenger steamers consists of 23 vessels, including eight which are operated jointly with the French State Railways on the Newhaven-Dieppe route. The latest additions to the fleet, "Isle of Thanet," "Maid of Kent" and the "Worthing," burn oil, and are all capable of over 22 knots.

In Southampton Docks the Southern Railway has a magnificent property, which has now become the first passenger port in the United Kingdom. It covers about 200 acres of land equipped with 42 miles of rail. (H. A. WA.)

SOUTHERN RAILWAY SYSTEM serves that part of the United States which is known historically as the Old South, and in modern economic statistics as the South-east. Its network of lines extend from the Potomac and Ohio rivers on the north to the Gulf of Mexico on the south and from the Mississippi river on the west to the Atlantic ocean on the east. The Southern Railway Company was chartered (1894) to acquire the properties which then constituted the Richmond and Danville and the East Tennessee, Virginia and Georgia systems, including many of the oldest railroads in the territory. These, with the South Carolina and Georgia railroad, the Cincinnati Southern railway, the Alabama Great Southern railroad, the New Orleans and Northeastern railroad, the Georgia Southern and Florida railway and the Northern Alabama railway, comprise the present system. The Mobile and Ohio railroad, operated separately, is affiliated.

The Southern Railway System operates 8,000 m. of railroad, has 60,000 employees, owns 2,300 locomotives, 78,000 freight cars and 1,400 passenger train cars, represents an investment in road and equipment of $771,000,000; and in the year 1928 performed a transportation service equivalent to the movement one mile of 11 billion tons of freight and one thousand million passengers. During the 35 years of life of Southern Railway Company the investment in road and equipment has increased 140% and the volume of freight traffic has increased 600%. (L. FO.)

SOUTHEY (sŭth'ĭ), **CAROLINE ANNE** (1786–1854), second wife of Robert Southey (*q.v.*), daughter of an East Indian captain, Charles Bowles. She was born at Lymington, Hants, on Oct. 7, 1786. She sent anonymously to Southey a narrative poem called *Ellen Fitzarthur,* and this led to the acquaintanceship and long friendship, which, in 1839, culminated in their marriage. *Ellen Fitzarthur* (1820) may be taken as typical, in its prosy simplicity, of the rest of its author's work. Soon after her marriage her husband's mental state became hopeless, and from this time till his death in 1843, and indeed till her own, her life was a sad one. Her correspondence with Southey, neglected in the official biography, was edited by Professor Dowden in 1881. Mrs. Southey died at Buckland Cottage, Lymington, on July 20, 1854, two years after Queen Victoria had granted her a pension of £200.

SOUTHEY, ROBERT (1774–1843), English poet and man of letters, was born at Bristol on Aug. 12, 1774. His father, Robert Southey, an unsuccessful linendraper, married Margaret Hill in 1772. When he was three, Southey passed into the care of Elizabeth Tyler, his mother's half-sister, at Bath, where most of his childhood was spent. In 1788 he was entered at Westminster school. After four years there he was privately expelled by Dr. William Vincent (1739–1815), for an essay against flogging called *The Flagellant,* written for a school magazine. His uncle, Herbert Hill, chaplain of the British factory at Lisbon, who had paid for his education at Westminster, determined to send him to Oxford with a view to his taking holy orders, but the news of his escapade at Westminster had preceded him, and he was refused at Christ Church. Finally he was admitted at Balliol, where he lived a life apart, and gained little or nothing except a liking for swimming and a knowledge of Epictetus.

Revolutionary Youth.—In the vacation of 1793 Southey's enthusiasm for the French Revolution found vent in writing an epic poem, *Joan of Arc,* published in 1796 by Joseph Cottle, the Bristol bookseller. In 1794 Coleridge, then on a visit to Oxford, was introduced to Southey, and filled his head with dreams of an American Utopia on the banks of the Susquehanna. The members of the "pantisocracy" were to earn their living by tilling the soil, while their wives cared for the house and children. Coleridge and Southey soon met again at Bristol, and with Robert Lovell developed the emigration scheme. Lovell had married Mary Fricker, whose sister Sara married Coleridge, and Southey now became engaged to a third sister, Edith. Miss Tyler, however, would have none of "pantisocracy" and "aspheterism," and drove Southey from her house. To raise the necessary funds for the enterprise Coleridge and he turned to lecturing and journalism. Cottle generously gave Southey £50 for *Joan of Arc;* and, with Coleridge and Lovell, Southey had dashed off the drama, printed as the work of Coleridge, on *The Fall of Robespierre.* A volume of *Poems* by R. Southey and R. Lovell was also published by Cottle in 1795. Southey's uncle, Mr. Hill, now desired him to go with him to Portugal. Before he started for Corunna he was married secretly (Nov. 14, 1795) to Edith Fricker. On his return to England he and his wife had lodgings for some time at Bristol. He was entered at Gray's Inn in February 1797. At the end of 1797 his friend Wynn began an allowance of £160 a year, which was continued until 1806, when Southey relinquished it on Wynn's marriage. His *Letters written during a Short Residence in Spain and Portugal* was printed by Cottle in 1797, and in 1797–1799 appeared two volumes of *Minor Poems* from the same press. In 1798 he paid a visit to Norwich, where he met Frank Sayers and William Taylor, with whose translations from the German he was already acquainted. He then took a cottage for himself and his wife at Westbury near Bristol, and afterwards at Burton in Hampshire. At Burton he was seized with a nervous fever which had been threatening for some time. He moved to Bristol, and after preparing for the press his edition of the works of Thomas Chatterton, undertaken for the relief of the poet's sister and her child, he sailed in 1800 for Portugal, where he began to accumulate materials for his history of Portugal. He also had brought with him the first six books of *Thalaba the Destroyer* (1801), and the remaining six were completed at Cintra.

Life at Greta Hall.—In 1801 the Southeys returned to England, and at the invitation of Coleridge, who held out as an inducement the society of Wordsworth, they visited Keswick. After a short experience as private secretary to Isaac Corry, chancellor of the exchequer for Ireland, Southey in 1803 settled at Greta Hall, Keswick, which he and his family shared thenceforward with the Coleridges and Mrs. Lovell. There he accumulated a library consisting of over 14,000 volumes, including valuable mss. and a collection of Portuguese authorities probably unique in England. After 1809, when Coleridge left his family, the whole household was dependent on Southey's exertions. His nervous temperament suffered under the strain, and he found relief in keeping different kinds of work on hand at the same time, in turning from the *History of Portugal* to poetry. *Madoc* and *Metrical Tales and Other Poems* appeared in 1805, *The Curse of Kehama* in 1810, *Roderick, the last of the Goths,* in 1814. This constant application was lightened by a happy family life. Southey was devoted to his children, and was hospitable. He met Walter Savage Landor in 1808, and their affection was lasting.

From the establishment of the Tory *Quarterly Review* Southey, whose revolutionary opinions had changed, was one of its most regular and useful writers. He supported Church and State, opposed parliamentary reform, Roman Catholic emancipation, and free trade. He did not cease, however, to advocate measures for the immediate amelioration of the condition of the poor.

With William Gifford, his editor, he was never on very good terms, and would have nothing to do with his harsh criticisms on living authors His relations with Gifford's successors, Sir J. T. Coleridge and Lockhart, were not much better. In 1813 the laureateship became vacant on the death of Pye The post was offered to Scott, who refused it and secured it for Southey. A government pension of some £160 had been secured for him, through Wynn, in 1807, increased to £300 in 1835. In 1817 the unauthorized publication of an early poem on *Wat Tyler,* full of his youthful republican enthusiasm, brought many attacks on Southey He was also engaged in a bitter controversy with Byron, whose first attack on the "ballad-monger" Southey in *English Bards and Scotch Reviewers* nevertheless did not prevent them from meeting on friendly terms Southey makes little reference to Byron in his letters, but Byron asserts (*Letters and Journals,* ed. Prothero, iv 271) that he was responsible for scandal spread about himself and Shelley. In this frame of mind, due as much to personal anger as to natural antipathy to Southey's principles, Byron dedicated *Don Juan* to the laureate, in what he himself called "good, simple, savage verse" In the introduction to his *Vision of Judgment* (1821) Southey inserted a homily on the "Satanic School" of poetry, unmistakably directed at Byron, who replied in the satire of the same name The unfortunate controversy was renewed even after Byron's death, in consequence of a passage in Medwin's *Conversations of Lord Byron*

Meanwhile the household at Greta Hall was growing smaller Southey's eldest son, Herbert, died in 1816, and a favourite daughter in 1826, Sara Coleridge married in 1829, in 1834 his eldest daughter, Edith, also married; and in the same year Mrs Southey, whose health had long given cause for anxiety, became insane She died in 1837, and Southey went abroad the next year with Henry Crabb Robinson and others. In 1839 he married his friend Caroline Bowles (*See* SOUTHEY, CAROLINE) But his memory was failing, and his mental powers gradually left him He died on March 21, 1843, and was buried in Crosthwaite churchyard A monument to his memory was erected in the church, with an inscription by Wordsworth

Works.—The amount of Southey's work in literature is enormous His collected verse, with its explanatory notes, fills ten volumes, his prose occupies about forty But his greatest enterprises, his history of Portugal and his account of the monastic orders, were left uncompleted, and this, in some sense, is typical of Southey's whole achievement in the world of letters, there is always something unsatisfying, disappointing, about him This is most true of his efforts in verse Some of Southey's subjects, "The Poet's Pilgrimage" for instance, he would have treated delightfully in prose, others, like the "Botany Bay Eclogues," "Songs to American Indians," "The Pig," "The Dancing Bear," should never have been written. Of his ballads and metrical tales many have passed into familiar use as poems for the young Among these are "The Inchcape Rock," "Lord William," "The Battle of Blenheim," and the ballad on Bishop Hatto

If we turn from his verse to his prose we are in a different world; there Southey is a master in his art, who works at ease with grace and skill "Southey's prose is perfect," said Byron, truly. His interest and his curiosity are unbounded as his *Common-Place Book* will prove, his stores of learning are at his readers' service, as in *The Doctor,* a rambling miscellany, valued by many readers beyond his other work. For biography he had a real genius. The *Life of Nelson* (2 vols., 1813), which has become a model of the short life, arose out of an article contributed to the *Quarterly Review;* he contributed another excellent biography to his edition of the *Works of William Cowper* (15 vols, 1833–1837), and his *Life of Wesley; and the Rise and Progress of Methodism* (2 vols, 1820) is only less famous than his *Life of Nelson.* But the truest Southey is in his *Letters:* the loyal, gallant, tender-hearted, faithful man is revealed.

A collected edition of his *Poetical Works* (10 vols, 1837–38) was followed by a one volume edition in 1847 Southey's letters were edited by his son Charles Cuthbert Southey as *The Life and Correspondence of the late Robert Southey* (6 vols, 1849–50), further selections were published in *Selections from the Letters of Robert Southey* (4 vols, 1856), edited by J W. Warter; and *The Correspondence of Robert Southey with Caroline Bowles To which are added. Correspondence with Shelley, and Southey's Dreams* (1881), was edited, with an introduction, by Professor E Dowden An excellent selection from his whole correspondence, edited by Mr John Dennis, as *Robert Southey, the story of his life written in his letters* (Boston, Massachusetts, 1887), was reprinted in Bohn's Standard Library (1894) *See* also *Southey* (1879) in the English Men of Letters Series, by Professor E Dowden, who also made the selection of *Poems by Robert Southey* (1895) in the Golden Treasury Series W Haller, *Early Life of Robert Southey (1774–1803)* (Columbia, 1917) A full account of his relations with Byron is given in *The Letters and Journals of Lord Byron* (vol vi, 1901, edited R E Prothero), in an appendix entitled "Quarrel between Byron and Southey," pp 377–399 Southey figures in four of the *Imaginary Conversations* of W S Landor, two of which are between Southey and Porson, and two between Southey and Landor.

SOUTH GEORGIA, an island in the South Atlantic Ocean, area 1,600 sq m It is mountainous, with snowy peaks 6,000 to 8,000 ft high, their slopes furrowed with deep gorges filled with glaciers Its geological constitution—gneiss and argillaceous schists, with no trace of fossils—shows that the island is, like the Falklands, a surviving fragment of some greater land-mass now vanished, most probably indicating a former extension of the Andean system South Georgia is politically attached to the Falklands, and since 1904 has been the chief centre for whaling. The chief settlement is at Grytviken on the north coast.

SOUTH HADLEY, a town of Hampshire county, Massachusetts, U S A, occupying 18 5 sq m on the Connecticut river, 12 m N of Springfield, directly opposite Mt. Tom. It is served by an electric line which connects with the Boston and Maine and the New York, New Haven and Hartford railways at Holyoke, across the river Pop (1920) 5,527 (25% foreign-born white), 1928 local estimate 7,200 South Hadley is the seat of Mount Holyoke college

SOUTH HOLLAND, the most crowded province of the Netherlands. area 1,133 sq m, and population (1926) of 1,814,536 showing the greatest increase per sq m during the 20th century It is a delta between the lower Maas and Waal It includes the detached island of Goeree-Over Flakkee, and other islands are Voorne-Putten, Rozemburg, Ysselmonde, Hoekschewaard, and Dordrecht The Hook of Holland harbour, built (1866–72) near Rotterdam, is an important approach to Central Europe from the east coast of Britain At Sassenheim in the extreme north there used to be Trilingen castle in which Jacqueline of Bavaria died (1433). Rynsburg was the home of Spinoza.

New coasts have appeared and new interests have arisen, though the Hague, situated on this old-village line, remains the political capital of the province and of the Netherlands (*q v*) Rotterdam (*q v*), Schiedam (43,000) and Dordrecht (55,000), Delft (49,000), Leyden (70,000) and Gouda (28,000) lie within the province Vianen on the Lek is reputed to be the *Fanum Dianae* of Ptolemy; Gorichem was one of the first towns to be taken (1572) from the Spaniards by the "Sea Beggars"

SOUTH KINGSTOWN, a town of Rhode Island, U S A Pop (1925), 6,085 It is an old tree-shaded town, on an arm of Point Judith salt pond, and has colonial houses In Great Swamp on Dec 19, 1675 the Narragansett Indians made their last stand in King Philip's War, and were defeated by the forces of the Massachusetts, Plymouth and Connecticut Colonies under Governor Josiah Winslow (of the Plymouth Colony)

SOUTH METROPOLITAN GAS COMPANY. This undertaking in London possesses by statute the sole right to supply gas to nearly the whole of the county of London south of the Thames, with nearly two million people. It is an amalgamation of supply companies, completed in 1885

In 1928 the South Metropolitan company had behind it a history of 104 years of enterprise It was in 1802 that William Murdock, the friend and assistant of Matthew Bolton and James Watt, lit with coal gas the famous engine works at Soho, near Birmingham, and gas lighting was used in London for the first time when the Carlton Palace Gardens were illuminated by an enterprising German named Winsor. The company, it will be seen, began work very soon after the first experiments were made Yet we may recall that as late as 1809 a scientist like Sir Humphry Davy declared that "it would be as easy to bring down a bit of the moon to light London as to succeed in doing so with gas." It is

also on record that in 1813 two gentlemen were prosecuted for making "divers noisome and offensive stinks" in experiment.

In 1928 the company had an issued capital of £9,739,340, upon which it pays dividends strictly limited by act of parliament. The company is identified with profit-sharing. In 1928 the stock held by employees amounted to over £500,000. (L. C. M.)

SOUTH MILWAUKEE, a city of Milwaukee county, Wisconsin, U.S.A., on Lake Michigan, 10 m. S. of Milwaukee; served by the Chicago and North Western and the Milwaukee Electric railways. Pop. (1920), 7,598 (27% foreign-born white); 1928 local estimate, 10,000. The city was founded in 1892 and incorporated in 1897.

SOUTH MOLTON, a town in Devonshire, England. Pop. (1921) 2,818. The remains of a British camp are visible 2 m. south of the town. The Domesday survey relates that the manor had been royal demesne of Edward the Confessor. It has a weekly market and a fair dating from 1246, and the fair which is held on St. John the Baptist's day, dates from 1490.

SOUTHOLD, a township of Suffolk county, New York, occupying the peninsula at the N.E. of Long island, and including the islands E.N.E. of this peninsula: Plum island, on which defences protect the eastern entrance to Long island sound, Little Gull island, Great Gull island and Fisher's island. Pop. (1920), 10,147. The mainland area is about 25 m. long and its average width is 2 m. A permanent settlement was made in 1640.

A meeting-house was built in 1642, and biblical laws were enforced. Southold was originally one of the six towns under the New Haven jurisdiction, but in 1662 was placed under Connecticut; in 1664 it objected strongly to the transfer of Long island to the duke of York; in 1670 refused to pay taxes imposed by Gov. Francis Lovelace of New York; in 1672 petitioned the king to be under Connecticut or to be a free corporation; in 1673, when the Dutch got control of New York, withstood the Dutch commissioners, with the help of Connecticut; and, in 1674, after English supremacy was again established in New York, still hoped to be governed from Connecticut. The township was chartered by Governor Edmund Andros in 1676.

See Epher Whitaker, *History of Southold, L.I.: Its First Century* (Southold, 1881); *Southold Town Records* (2 vols., Southold, 1882–84); Peter Ross, *A History of Long Island* (1902); Ella B. Hallock, *The Story of the 275th Anniversary Celebration of the Founding of Southold Town* (1915); B. F. Thompson, *History of Long Island* (1918).

SOUTH ORANGE, a village of Essex county, New Jersey, between Orange and Maplewood. Pop. (1920) 7,274 (80% native white). It is a residential community, 300 ft. above sea-level. Among the landmarks are an old stone house mentioned in documents as early as 1680, the Baldwin house (*c.* 1717), and the Timothy Ball house (1743).

SOUTH PASADENA, a city of Los Angeles county, California, U.S.A. Pop. (1920) 7,652 (87% native white); 1928 local estimate, 15,000. It is primarily a residential suburb. There is an ostrich farm which attracts many visitors.

SOUTHPORT, seaside resort, Lancashire, England. Pop. (1921) 76,621. It is a favourite holiday resort.

The great promenade along the shore is 2 m. in length; in its centre is the pier, 1 m. long. Lord Street, the main thoroughfare, is an excellent boulevard. Other facilities for outdoor enjoyment are provided in Hesketh Park, the Botanic Gardens, Kew Gardens, South Marine Park, and the Winter Gardens. Southport was incorporated in 1867, became a county borough in 1905 and a parliamentary borough in 1918.

SOUTH PORTLAND, a city of Maine, U.S.A., opposite Portland, with which it is connected by four bridges and a ferry. Pop. (1920) 9,254 (88% native white); 1928 local estimate 12,000. It is the seat of the State reform school for boys. Until 1895 South Portland was part of the town of Cape Elizabeth.

SOUTH RIVER, a borough of New Jersey, U.S.A., served by the Raritan River railroad. Pop. (1920) 6,596 (40% foreign-born white); 1928 local estimate 12,000. There are large brick and tile works. The profit from the public utilities owned and operated by the borough meets the costs of the government. A settlement was established here in 1720 by Samuel Willett. The borough was incorporated in 1896.

SOUTHSEA: *see* PORTSMOUTH.

SOUTH SEA BUBBLE, the name given to a series of financial projects which originated with the incorporation of the South Sea Company. In 1711 the South Sea Company was formed, and was granted a monopoly of the British trade with South America and the Pacific islands. It was highly successful, and early in 1718 the king became its governor. Towards the end of 1719 the directors of the company put before the Government, the head of which was Charles Spencer, 3rd earl of Sunderland, a more ambitious scheme. In return for further concessions the company offered to take over the whole of the national debt (£51,300,000) and to pay £3,500,000 for this privilege. The aim of the directors was to persuade the annuitants of the State (the bulk of the debt was thus held) to exchange their annuities for South Sea stock; the stock would be issued at a high premium and thus a large amount of annuities would be purchased and extinguished by the issue of a comparatively small amount of stock. Moreover, when this process had been carried out the company would still receive from the Government a sum of something like £1,500,000 a year in interest. The offer was accepted in 1720, the company having raised its bid to £7,567,000 in competition with the directors of the Bank of England.

In a few weeks the company had persuaded over one-half of the Government annuitants to become shareholders in the company. Meanwhile the stock of the company had been appreciating steadily in value, and when the new scheme was launched the public began to purchase it eagerly. From 128½ at the beginning of the year the price had risen by June to 890, and in July it touched 1,000. At this tremendous premium the directors sold five millions of stock. The extraordinary success of the company produced a crowd of imitations—many of them audacious hoaxes—and the wild speculation which followed involved the numerous honest companies in disaster. In August the fall in the price of South Sea stock began. By November it had fallen to 135, and in four months the stock of the Bank of England fell from 263 to 145. Thousands were ruined, and many who were committed to heavy payments fled from the country. A committee of secrecy of the House of Commons reported in February 1721. The company's books contained fictitious entries, and it was shown that favours secured from the State had been purchased by gifts to ministers, some of whom had also made large sums of money by speculating in the stock. The chief persons implicated were John Aislabie (1670–1742), chancellor of the exchequer; James Craggs, joint postmaster-general; his son James Craggs, secretary of state; and to a lesser degree the earl of Sunderland and Charles Stanhope, a commissioner of the Treasury. Aislabie resigned his office in January, and being found guilty of the "most notorious, dangerous and infamous corruption," was expelled from the house and imprisoned. Both the elder and the younger Craggs died in March, while, owing to the efforts of Walpole, both Sunderland and Stanhope were acquitted, the latter by the narrow majority of three. By act of Parliament the estates of the directors were confiscated; these were valued at £2,014,123, of which £354,600 was returned to them for their maintenance, the balance being devoted to the relief of the sufferers. The South Sea Company continued to exist, without any great prosperity, until the 19th century.

SOUTH SHETLAND, a chain of islands on the border of the Antarctic region, lying about 500 m. S.E. of Cape Horn, and separated by Bransfield Strait from Graham Land. Deception Island is of volcanic origin, but Otto Nordenskjöld (*Antarctica*, London, 1905) found no exterior evidence of volcanic activity.

Most of the islands are rocky and mountainous, and some peaks are between 6,000 and 7,000 ft. in height. Covered with snow for the greater part of the year, and growing nothing but lichens, mosses and some scanty grass, the South Shetlands are of interest almost solely as a haunt of seals, albatrosses, penguins and other sea-fowl. In 1819 William Smith of the English brig "Williams" observed the South Shetland coast on the 19th of February. Revisiting it in October, he landed on King George I. Island, taking possession for England; he also gave the whole chain the name it bears. A smaller group lying 200 m. east of the

South Shetlands, bears the name of South Orkney It was discovered by the English captain, Powell, in 1821

SOUTH SHIELDS, seaport, Durham, England, on the Tyne Pop.* (1921) 116,635. It is connected with North Shields and Tynemouth by steam ferries The church of St Hilda has a picturesque old tower. The Tyne dock has an area of 50 ac, the tidal basin of 10 ac, and the quays and yards over 300 ac Coal is largely exported (*See* NEWCASTLE-UPON-TYNE) The South Pier is a massive structure about 1 m long, and the North Pier protects the river mouth from the Northumberland bank at North Shields. Constant dredging maintains a depth of 30 ft. Near the harbour is a Roman fort, where coins etc. have been dug up This site was afterwards occupied by a fort, which was captured by the Scots in 1644 The town was founded by the convent of Durham in the 13th century, but until the 19th century it was only a fishing station. In 1832 it was given a member to parliament, and in 1850 a charter of incorporation.

SOUTHWARK, a central borough of London. Pop (1921) 184,404; area 1,131 acres The borough is connected with the City of London by Blackfriars, Southwark and London bridges; the thoroughfares converge at St. George's Circus; another important junction is the "Elephant and Castle."

The name is taken from the southward works or fortifications of London. Numerous Roman remains have been found Southwark witnessed various episodes during the invasions of the Norsemen, and was fortified by the Danes against the City in the reign of Ethelred the Unready Besides the priory of St. Mary Overy, there was the hospital of St Thomas, founded in 1213 from the neighbouring priory of Bermondsey, being the origin of the modern hospital of the same name in Lambeth (*q v*). Bordering the river (Bankside) was Winchester House, a seat of the bishops of Winchester for five centuries from 1107.

The convergence of roads to cross London Bridge gave Southwark its mediaeval importance and its inns became famous (*e g*, the "*Tabard*" of the Canterbury Tales) At an early date it was incorporated, and its familiar title of "The Borough" still survives It came, at least in part, under the jurisdiction of the City in 1327. Edward III granted the city forever the town and borough of Southwark, a privilege confirmed by Edward IV. In this connection was constituted the Bridge Ward Without, the alderman of which is elected not by the borough, but by the other aldermen from among themselves The authority of the City over the borough is now merely nominal.

At Bankside were the Bear and the Paris Gardens and the Globe theatre, the scene of the production of many of Shakespeare's plays for fifteen years after its erection in 1599

Southwark is a bishopric of the Church of England created by act of 1904 (previously a suffragan bishopric in the diocese of Rochester), and also of the Roman Catholic Church The cathedral of St. Saviour belonged to the Augustinian priory of St. Mary Overy, or Overies (*i e*, St Mary over the river)

SOUTHWELL, ROBERT (*c.* 1561–1595), English Jesuit and poet, son of Richard Southwell of Horsham St Faith's, Norfolk, was born in 1560/61. He was educated at Douai and at Paris, joining the Society of Jesus In 1584, an act was passed, forbidding any English-born subject of the Queen who had taken priest's orders in the Roman Catholic Church since her accession to remain in England longer than forty days on pain of death. But Southwell at his own request was sent to England in 1586 as a Jesuit missionary with Henry Garnett. He went from one Catholic family to another, administering the rites of his Church, and in 1589 became domestic chaplain to Ann Howard, whose husband, the first earl of Arundel, was in prison convicted of treason. It was to him that Southwell addressed his *Epistle of Comfort.* This and other of his religious tracts, *A Short Rule of Good Life, Triumphs over Death, Mary Magdalen's Tears* and a *Humble Supplication to Queen Elizabeth,* were widely circulated in manuscript. That they found favour outside Catholic circles is proved by Thomas Nashe's imitation of *Mary Magdalen's Tears* in *Christ's Tears over Jerusalem*

After six years of successful labour Southwell was arrested (1592). He was imprisoned at first in Richard Topcliffe's house, where he was repeatedly put to the torture in the vain hope of extracting evidence about other priests Transferred to the gatehouse at Westminster, he was so abominably treated that his father petitioned Elizabeth that he might either be brought to trial and put to death, if found guilty, or removed in any case from "that filthy hole" Southwell was then lodged in the Tower, but he was not brought to trial until Feb 1595. Much of his poetry, none of which was published during his lifetime, was probably written in prison. On Feb 20, 1595, he was tried before the court of King's Bench on the charge of treason, and was hanged at Tyburn on the 21st.

St Peter's Complaint with other Poems, published anonymously in 1595, was reprinted thirteen times during the next forty years A supplementary volume entitled *Maeoniae* appeared later in 1595, and *A Foure fould Meditation of the foure last things* in 1606. This, which is not included in Grosart's reprint (1872) in the Fuller Worthies Library, was published by Mr Charles Edmonds in his *Isham Reprints* (1895) *A Hundred Meditations of the Love of God,* in prose, was first printed from a ms at Stonyhurst College in 1873

See Sidney Lee's account in the *Dict. Nat. Biog*; Alexis Possoz, *Vie du Père R Southwell* (1866), and a life in Henry Foley's *Records of the English Province of the Society of Jesus* (1877, i 301–387) Foley's narrative includes copies of the most important documents connected with his trial, and gives full information of the sources

SOUTHWELL (SUDWELLE, SUWELL, SUTHWELL), a cathedral city of Nottinghamshire, England, 16 m N E of Nottingham on the L M S Pop (1921) 3,085 The foundation of the earliest church and possibly of the earliest settlement is attributed to Paulinus (7th century) Another church followed after the devastations of the Northmen, in 960, on the foundation of King Edgar In 958 land at Southwell was granted to the archbishop of York by Edwy A detailed description of the great manor is given in Domesday The building of the present church began in the reign of Henry I Southwell remained under the lordship of the see of York until it was taken over by the ecclesiastical commissioners King Henry VIII, after the dissolution of the monasteries, contemplated the erection of the church into a cathedral The cruciform cathedral is 306 ft in length, with a Norman nave The archbishops of York had a palace here dating from the 15th century The "great chamber" was restored in 1882, and since 1904 the building has been converted into a residence for the bishops of Southwell The episcopal see was founded in 1884 In 1927 the diocese was divided—a new see being established at Derby

SOUTH-WEST AFRICA. A mandated territory in South Africa, formerly German South-West Africa Its area is 312,194 sq m, excluding the strip extending to the Zambezi, and known as the Caprivi Zipfel, which has been attached to the Bechuanaland Protectorate The country extends from 17° S to 28° 57′ S, and from the Atlantic ocean to 21° E It is bounded on the north by Angola, on the east by the Bechuanaland Protectorate and the Cape Province of the Union of South Africa, on the south by the Cape Province, and on the west by the Atlantic ocean The northern boundary follows the Kunene and Okavango rivers for a considerable distance

Physical Features.—The greater part of South-West Africa forms part of the high plateau of South Africa, the general elevation being between 3,000 and 4,000 feet The edge of the plateau is well defined in the north and south of the country, but is indefinite in the centre The highest part of South-West Africa is about Windhoek, where the Khomas Hochland reaches up to 6,700 ft, the Onyati mountains attain a height of 7,198 ft, and the Auas mountains rise in their highest point, Molteblick, to 7,886 feet. Between the high plateau and the Atlantic is the Namib desert, which slopes regularly toward the sea, attaining its greatest width toward the south, and having an average width of about 60 miles On the plateau, especially in the east and north, occur many shallow depressions, or pans, up to 2 m across In the wet season they may contain fresh, brackish, or salt water, in the winter the salt pans dry up and become encrusted with salt The Etosha pan cannot, perhaps, be classified with these smaller occurrences In the winter it, too, may be dry, but in

the rainy season it is covered by a sheet of shallow water. Its extent is 1,355 sq. miles.

The climate is hot and dry. Along the coast the rainfall is about 1 in. per annum; inland, it increases from 6 in. in the south to 12 in. in the centre and 22 in. in the north. The low rainfall along the coast is partly explained by the cold Benguela current, which flows northward, and is responsible for much fog and comparatively low temperatures along the coastal lands. Except for the Kunene and Okavango rivers in the north, and the Orange in the south, there are no perennial streams. Fresh water can be obtained from shallow wells in the sandy beds of the intermittent streams.

Vegetation.—The Namib is almost devoid of vegetation near the coast, except for such plants as can exist, on account of the fogs, e.g., *Sarcocaula, Aloe dichotoma,* and the *Welwitschia mirabilis.* About 25 m. inland cacti and euphorbias appear, and in the river channels thorn trees (Acacia spp.) occur. On the plateau, in the south, semi-desert conditions prevail, low shrubs and scant grass being the chief plants, with trees along the river beds. The commonest plants here are *Salsola aphylla* (the Ganna bush), *Rhigozum trichotomum* (the three thorn bush), *Acacia giraffae* (Kameeldoorn), and species of aloes and euphorbias. Northward, as far as Rehoboth, karroo conditions are characteristic. Then a park-like grass country is reached, studded with thorn trees. From about Windhoek the country is covered with bush, mostly of thorn trees. Toward the north the bush becomes thicker, and includes belts of Mopane forest; about the Okavango the vegetation becomes richer and more tropical.

Population.—In 1921 the population included 177,462 Bantu, 30,845 other natives and coloured, and 19,432 Europeans. The latter had increased by 1926 to 24,115. Among the non-European inhabitants are Bushmen, Hottentots, Damara, Herero, Ovambo. (*See* separate articles.) For the accommodation of these people reserves have been set aside. The only towns with a European population of more than a thousand, in 1926, are Windhoek (3,809), which also has about 4,000 natives, and is the administrative capital; Luderitz (1,234), a small seaport; Keetmanshoop (1,159), the centre of a small mining industry, 180 m. E. of Luderitz Bay; and Swakopmund (1,125). The last will probably cease to grow, since shipping has been diverted to its young, but more conveniently situated rival, Walvis Bay (*q.v.*).

Occupations.—In the moister northern area, maize, potatoes, pumpkins and beans are grown, but the climate elsewhere is too dry for much agriculture. Farther south, along the Avob river are several good artesian wells, which offer opportunities for irrigation and the growth of wheat. In 1926 there were, in South-West Africa, 1,650 farms, with 12,351 morgen under crops, the area devoted to maize being 9,241 morgen. The country is more suitable for pastoralism. In the drier areas of the south and centre, sheep and goats are kept, while in the north, and in parts of the centre, cattle thrive. The following figures give the numbers of live stock in the country:—Cattle, 567,798; sheep, 1,174,958; goats, 967,720; donkeys, 45,363; horses, 16,160. In addition to these there were, in the native reserves, 53,566 large stock and 221,157 small stock.

The following minerals were exported in 1926:—Copper ore, 41,967 tons (£319,000), almost entirely from about Tsumeb; alluvial diamonds, 638,801 carats (£2,000,752); cassiterite, 198·9 tons (£39,500). Other minerals, such as iron, marble and gold, are believed to occur, but are not being exploited. The output of vanadium in the Grootfontein area is increasing.

Administration.—The administration of South-West Africa is vested in the Government of the Union of South Africa. The country, exclusive of Ovampoland, a native area, is divided into 17 magisterial divisions, under magistrates, who have administrative and judicial powers. At the head is the administrator, assisted by an executive of four other members, who are chosen by the Assembly from its own members. By the addition of these other members, chosen by the administrator and approved by the governor-general, the executive may become an advisory council. The Legislative Assembly, established, like the executive committee and the advisory council, in 1925, consists of 18 members, 12 being elected and six being appointed by the administrator, subject to the approval of the governor-general. It has powers to legislate on all matters, except such as are expressly reserved, *e.g.,* native affairs, railways, immigration, banking, etc. The Roman-Dutch law of the Cape Province is administered throughout the territory, together with ordinances, passed by the Legislative Assembly, and some portions of German law.

(R. U. S.)

RECONSTRUCTION

After the conquest of German South-West Africa in 1915 by the Union forces under Gen. Botha the conquered territory was placed under martial law. The German troops were interned and subsequently (in 1919) repatriated, together with some 600 "undesirables." German civilians were allowed to return to their homes and continue their ordinary business. They gave the authorities no serious trouble, partly because they believed in the ultimate victory of Germany in the World War. This was evidenced by the local banks and traders maintaining a rate of exchange of 24 marks to the £ sterling until Nov. 1918. When this artificial rate broke down serious losses followed. The Germans, however, continued to entertain false hopes and after the armistice they appealed to President Wilson for help on "self-determination" lines, saying that they wished to become an autonomous republic leagued to Germany. They got no satisfaction from Wilson and were told (Oct. 1919) by the governor-general of the Union, Lord Buxton, that the severance from Germany was irrevocable. But the Germans, numbering 8,000, still desired to live under the German Civil Code.

In 1923 Gen. Smuts, prime minister of the Union, in London, made an arrangement with Germany; and this arrangement was given legal sanction by an act of the Union parliament (Act 30 of 1924) and in the result out of 3,489 German adults only 261 refused to accept British nationality. At that time (1925) there were fully 10,000 non-German white settlers in the country, the majority South Africans.

The constitutional position was clear. By the Treaty of Versailles Germany ceded her colonies to the principal Allied and Associated Powers and the mandate for its administration was conferred on "his Britannic majesty for and on behalf of the Government of the Union of South Africa." By the terms of the mandate the country could be governed by the mandatory as if it were an integral part of its own territory. Martial law ended on Jan. 3, 1921.

The mandatory had undertaken to treat the Germans "as part of the people, with the same privileges and the same responsibilities as the others." By Act 42 of 1925 of the Union parliament a legislative assembly for South-West Africa was set up. The territory was divided into 12 constituencies, each electing one member. The franchise was confined to adult European males and the electors numbered some 6,500. Besides the elected members, six members were nominated by the Union Government. An executive committee of five members, under the chairmanship of the administrator, was elected by the assembly, which met first in June 1926. Its functions were severely limited; it had less power than the provincial councils in the Union, for it had no control of education. Nevertheless, it served a useful purpose. In 1928 the administrator was able to refer to the healthy financial state of the country, to the success of the land settlement schemes and to the increase of immigration and of trade. Arrangements were made (1928–29) for the settlement in the territory of some 300 Boer families living in southern Angola.

Native Affairs.—In general the natives accepted Union rule willingly. In 1917 it was found necessary to send a military force into Ovamboland, where German authority had been very slight. Excellent relations were established with the Ovambo. In 1922 the Bondelzwart Hottentots, irritated by certain regulations with regard to cattle-branding, taxes on dogs and other matters, rose in revolt. The rising was suppressed with considerable loss of life and in a manner which gave rise to justly adverse criticism. In 1925 the Bastaards or Rheoboths, a small Dutch-speaking

sept with much white blood, who had a *raad* (parliament) of their own, claimed complete autonomy and defied the authorities. On this occasion much tact and patience were shown and the difficulty was overcome without bloodshed. For most of the tribes large reserves were provided, the chief trouble, in an arid country, being to secure them adequate water supplies In the legislative assembly, one member of the administrative advisory council is charged with the care of native interests Largely because of the native troubles an inquiry by the Permanent Mandates' Commission into the administration of the mandate was held in November, 1928

Sir Howard Gorges governed the country in the martial law period; he was succeeded (Oct. 1920) by Gysbert Hofmeyr, after whom A J Werth became administrator (June 1925)

See the *Official Year Book of the Union of South Africa · No 8* (Pretoria, 1927), and the annual reports to the League of Nations. *See* also MANDATE. (F R. C)

SOUTH-WEST AFRICA, CAMPAIGN IN. For some time before the year 1914 the proximity of the German Protectorate of South-west Africa, sharing a common frontier on its southern and eastern borders with the Union of South Africa, had been recognized by the Government of the latter country as an important factor in its military arrangements

On Aug 6, 1914, the Union Government undertook to assume all obligations resting upon the British regular garrison in South Africa, and on Aug 10, to send a military expedition of its own against German South-west Africa The British Government accepted both offers, and indicated the enemy seaports and the wireless installation in Windhoek as the first objectives In September a mixed force under Brig -Gen Lukin was landed at Port Nolloth and disposed thence eastwards along the southern enemy border to Steinkopf, the line of observation being continued to Upington by another force under Lt -Col Maritz The first Union troops to occupy enemy territory were those commanded by Col Beves, which landed unopposed at Luderitz bay on Sept 18 On Sept 9 Maritz joined the Boer rebellion and deserted to the enemy Though only 11,000 rebels took the field, 30,000 loyal troops acted against them and offensive action against the enemy was delayed for four months A Union detachment with two guns was captured at Zandfontein on Sept 26, a reverse due to Maritz It was thus only on Feb 11, 1915 that Botha took command at Swakopmund

Disposition of Forces.—The position then was that the northern force (Gen Botha) held Walvis bay and Swakopmund, facing the troops of the enemy chief command (Lt -Col Franke) The central force (Brig -Gen Sir D McKenzie) occupied Luderitz bay with its forward troops at Tshaukaib, 40m inland, in touch with the enemy on the railway line to Keetmanshoop The southern force (Brig -Gen Van Deventer) watched the German force (Maj Ritter) on the southern enemy border The eastern force (Col Berrangé), considerably smaller than the rest, was mobilizing for an advance along the Kuruman and Molopo rivers against the eastern border of the enemy, whose detachments here lay at Rietfontein and Hasuur The Royal Navy conveyed, escorted and disembarked the whole of the forces and their supplies from the base at Cape Town

The theatre of the campaign, 322,350sq m in area, is a plateau 3,500ft above sea level A waterless tract, 40 to 100m broad on the coast side and 200m inland, intervenes between the first rise to the plateau and the border Water is scarce everywhere, and the water holes were well known and far apart The railways were much damaged by the enemy, and the Union engineers repaired 1,040m. and laid 340m of new line during the campaign The enemy forces consisted of 2,000 soldiers and 140 officers, and in addition 7,000 male Europeans, many with military training. Of military material and equipment the German commander had abundance; he enjoyed throughout a substantial advantage in respect of artillery.

Botha's Campaign.—On Feb. 23, Gen. Botha moved from Swakopmund and secured Rössing on the railway line and Husab on the Swakop river. The river route was selected for the main advance, and on March 18, after careful and tedious preparations, Gen Botha again advanced and heavily defeated the enemy at Riet and Pforte in the Swakop valley, capturing two guns and 284 prisoners Sixty miles of the river route were now secured, and, after another period of preparation, a third advance was made on April 26 and Karibib occupied on May 5, after a series of rapid turning movements by mounted troops The enemy withdrew to the north, and Windhoek was occupied on May 12

The Auxiliary Movements.—Gen Botha's infantry (Skinner) had meantime advanced along the railway and occupied Usakos On March 30 the central force occupied Aus, and on April 26 at Gibeon, McKenzie's mounted troops, after rapid sustained marching, overtook and heavily attacked the enemy retiring from the south The eastern force (Berrangé) left Kuruman on March 6 and joined hands with the southern force on April 20 at Kabus The southern force (Gen Smuts) defeated the enemy at Nabas on March 8 and at Kabus on April 20 The capital occupied, the southern area was conquered

A conference between the Union commander and Gov Seitz at Giftkuppe on May 21 proved abortive, and the final stage of the campaign against the enemy, now concentrated in the north, ensued Gen Botha advanced from Karibib on June 18 The main body (mounted troops and infantry) moved in the centre with the commander-in-chief, while strong mounted forces operated to the east and west, commanded respectively by Myburgh and Brits The enemy retired rapidly, and on June 27 Brits was ordered to move widely to the north-west and head the enemy off at Namutoni, while Myburgh was to swing in on Tsumeb from the east These movements were carried out exactly, and the enemy, defeated on July 1 at Otavi by the leading mounted brigade of the centre, forestalled at Namutoni, and having lost Tsumeb, surrendered on July 9, 1915

SOUTH-WESTERN ISLANDS or **SERWATTI ISLANDS,** the name of two chains of islands in the Banda sea, of the Malay Archipelago Wetar, the largest island, is 70 m. by 20 miles

Administratively the islands form part of the residency of Amboyna The estimated population of all the islands is about 40,000, Wetar, which is uncivilized, having 7,500 Kisar has as settlers the descendants of European soldiers of the time of the old Dutch East India Company

SOUZA-BOTELHO, ADÉLAIDE FILLEUL, MARQUISE DE (1761–1836), French writer, was born in Paris on May 14, 1761 Her mother, Marie Irène Catherine de Buisson, daughter of the seigneur of Longpré, near Falaise, married a bourgeois of that town named Filleul It was reported, though no proof is forthcoming, that Mme Filleul had been the mistress of Louis XV Her husband became one of the king's secretaries, and Mme Filleul made many friends, among them Marmontel Their eldest daughter, Julie, married the marquis de Marigny (1727–1781), Adélaide married in 1779 Alexandre de Flahaut de la Billarderie, comte de Flahaut, who was many years her senior In Paris she soon gathered round her a salon, in which the principal figure was Talleyrand There are many allusions to their liaison in the diary of Gouverneur Morris In 1785 was born her son Auguste Charles Joseph de Flahaut (*q v*), who was generally known to be Talleyrand's son Mme de Flahaut fled from Paris in 1792 and joined the society of *émigrés* at Mickleham, Surrey, described in Mme d'Arblay's *Memoirs* Her husband remained at Boulogne, where he was arrested on Jan 29, 1793, and guillotined Mme de Flahaut now supported herself by writing novels, of which the first, *Adèle de Sénange* (London, 1794), which is partly autobiographical, was the most famous. She presently left London for Switzerland, where she met Louis Philippe, duke of Orleans She travelled in his company to Hamburg, where she lived for two years, earning her living as a milliner She returned to Paris in 1798, and in 1802 she married José Maria de Souza-Botelho Mourão e Vasconcellos (1758–1825), Portuguese minister plenipotentiary in Paris Mme de Souza lost her social power after the fall of the First Empire She died on

April 19, 1836. She brought up her grandson, Charles, duc de Morny, her son's natural son by Queen Hortense.

SOVA, ANTONIN (1864–), Czech poet, began his literary career early in the '90s with verse, describing Prague and his native region of Southern Bohemia. His introspective poems, in *Lyrics of Love and Life, Mastered Sorrows* and *Once Again Shall We Return,* include good lyrics, and he has been compared with Verlaine. Disillusionment drove him to seek escape in visionary poems which reveal symbolism. In 1913 appeared *Harvests,* a volume in which reconciliation predominates. The later poems are written with the crystalline simplicity of folk songs, and in some Sova is the spokesmen of Czech aspirations. He also wrote novels and short stories.

SOVEREIGN: *see* POUND.

SOVEREIGNTY. While society is in a rude state or only tribally organized there is no distinct sovereignty, no power which all persons habitually obey. Thus there is no sovereignty among wandering groups of Australian savages: each family is isolated, each horde is a loose and unstable collection. When the horde has become a tribe there may exist no definite sovereign. Distinct in time of war, the power of the chief may be fluctuating and faint in time of peace; even in time of war it may be subject to the authority of a council. Tribes of the same ethnic stock may form a sort of federation, permanent or temporary. "With the council of the confederacy," it has been said, "and, more generally, in the confederacy, sovereignty arises and the true political tradition is evolved" (F. H. Giddings, *Principles of Sociology,* p. 285). When the city and the State are conterminous the seat of sovereignty becomes defined. Such was the condition of things in Greece, as considered by Aristotle in his *Politics.* He discusses the question what is the supreme power in the State (3. 10), which he defines as an aggregate of citizens (3. i.), and he recognizes that it may be lodged in one, a few, or many. In his view the distinctive mark of the State is not so much sovereignty (7. 4) as self-sufficiency; a State is not a mere aggregate of persons; it is a union of them sufficient for the purposes of life (7. 8). The early Roman jurists speak little of sovereignty. But later, with the belief in the existence of an empire entitled to universal sway, an absolutist theory of sovereignty was developed in the writings of jurists.

Among the theories prevalent in the middle ages was one that mankind formed a unity, with the pope and the emperor at the head of it: the universal church and the universal emperor ruled the world. (Rehm, *Geschichte der Rechtswissenschaft,* p. 198). When the power of the emperor was weakened, and the idea of a universal ruler was gone, a new test of sovereignty was applied —that of external independence; the true sovereign States were *universitates superiorem non recognoscentes.* There were times and countries in the middle ages in which the collective power of the community was small: many of the great corporations were virtually autonomous; the central authority was weak; the matters as to which it could count upon universal obedience were few. In such circumstances the conception of sovereignty was imperfect. The modern theory is first clearly stated in Jean Bodin's book *On the Commonwealth* (French ed., 1576; Latin version, 1586). He writes thus: "Respublica est familiarum rerumque inter ipsas communium, summa potestate ac ratione moderata multitudo." His theory, which corresponded to the France of Louis XI., was a theory of despotism.

One favourite theory was that sovereignty originated in a social contract. Hobbes, in his *Leviathan* expounded his notion of an agreement by which absolute power was irrevocably transferred to the ruler. Rousseau assumes his famous *pacte social,* the terms of which are: "Chacun de nous met en commun sa personne et toute sa puissance sous la suprême direction de la volonté générale; et nous reçevons encore chaque membre comme partie indivisible de tout" (*Du Contrat social,* 1. c. 6).

Among the different senses in which "sovereign" has been used are the following:—

a. "Sovereign" may be titular—the king in Great Britain.

b. The legal sovereign: the person or persons who, according to the law of the land, legislate or administer the government.

c. The political or constitutional sovereign: the body of persons in whom the actual power at any moment or ultimately resides. Sometimes this is designated "the collective sovereignty."

d. Sovereignty is also used in a wider sense, as the equivalent of the power of the whole nation or society (Gierke; 3. 568).

The distinction between real and nominal sovereignty was familiar to mediaeval writers, who recognized a double sovereignty, and distinguished between (1) the real or practical sovereignty resident in the people, and (2) the personal sovereignty of the ruler (Adolf Dock, *Der Souveranitätsbegriff,* etc., p. 13).

Sometimes sovereignty is defined as the organized or general will of the community. "Sovereignty resides in the community" (Woodrow Wilson).

This was the belief in the French Revolution. "Sachez que vous êtes rois et plus des rois," said a revolutionary orator cited by Taine. It was the language of the founders of the American constitution and contemporary political writers.

The same theory assumes a more subtle form, especially in the writings of Hegelians. Sovereignty is with them a term descriptive of the real will of the community, which is not necessarily that of the majority.

Sovereignty is used in a further sense when Plato and Aristotle speak of the sovereignty of the laws (*Laws,* 4. 715; *Politics,* 4. 4; 3. 15). Thus Plato remarks: "I see that the State in which the law is above the rulers, and the rulers are the inferiors of the law, has salvation." (*See* also Gierke, *Genossenschaftsrecht,* 3. 8.) Even in mediaeval writers, such as Bracton, is found the notion that the king is subject to the laws (J. N. Figgis, *The Divine Right of Kings,* p. 13). We find the same expressed by many German jurists (Gierke iii., x.). In *Der Souveranitätsbegriff im Bodin,* etc., by Adolf Dock [1897] p. 6, and in *La Conception juridique de l'état,* by Combothecra, p. 90. There are many definitions—some ideal—of sovereignty.

Half Sovereign States.—The phrase *half sovereign States* was invented by J. J. Moser to describe States possessing some of the attributes of sovereignty. Under this class are grouped very diverse communities.

Feudalism had terms to express the varieties of fiefs which existed under it; modern international law has no generally-accepted terminology for the still greater variety of States which now exist. These varieties tend to multiply, and it is difficult to reduce them all to a few types. The theory that States are equal, and possess all the attributes of sovereignty, was never true. It is still more at variance with the facts in these days when a few great States predominate, and when the contact of western States with African and Asiatic States or communities gives rise to relations of dependence falling short of conquest. We have:

1. States which have complete independence, complete autonomy, external and internal, and which are recognized in international law as sovereign States.

2. States which have complete external independence, but are more or less subject permanently to other States as to their internal affairs. Of this class there are now few examples.

3. States which enjoy complete autonomy as to internal affairs, but which are more or less subject to other States as to foreign relations. These are some examples:—

a. Protectorates and Suzerainties (*q.v.*).

b. The unions between a superior and inferior State, *e.g.,* the relations of the various States to the old Holy Roman empire; the relations of the Ottoman Porte to its Christian provinces. In the middle ages the question was often mooted whether States subject to feudal superiors, or the States forming the empire, were sovereign. Grotius (1. 1. ch. 3, 23. 2), holds that the *nexus feudalis* is consistent with *summum imperium.*

4. States which have, by treaty or otherwise, parted with some portion of their sovereignty and formed new political units: what Herbert Spencer calls "compound political heads." For years one of the burning questions in the politics of the United States was the question whether the individual States of the Union remained sovereign.

5. Another division includes anomalous cases, such as Egypt, in which one Government administers a country as to which another State retains certain powers.

6. The territories governed or administered by chartered companies form a class by themselves Nominally such companies are the delegates of some States; in reality they act as if they were true sovereigns.

7 Two other classes may be mentioned. (*a*) cases of real union between States, as formerly between Austria and Hungary; (*b*) personal unions, distinguished from the above-named forms—*e g*, the union of Great Britain and Hanover

8. A small group consists of instances of *condominium* or arrangements similar thereto, *e g.*, the arrangements as to the Samoa islands from 1889 to 1899

According to modern usage the appellation "sovereign State" belongs only to States of considerable size and population exercising without control the usual powers of a State, *e g*, able to declare peace or war

Colonies.—It is sometimes suggested that self-governing colonies are to be regarded as true States. Undoubtedly some of them can no longer be regarded as colonies in the old sense. The self-governing colonies forming part of the "multicellular British State," as F W. Maitland describes it (*Political Theories of the Middle Ages,* p x), have an essentially "state-like character." If Liberia is a State, the same may surely be said of Canada

With the creation of the League of Nations, however, the theory of sovereignty has become still more academic and impracticable India and the Dominions are equal members with Great Britain of the League As a member of the League the sovereignty of Great Britain is limited to the same extent as that of Ireland or any other member And there are at least a dozen States in Europe members of the League, which enjoy, both in fact and in law, less independence than the dominions The old distinction between sovereign and non-sovereign States has ceased to exist A sovereign State is now obsolete Even the United States is not absolutely sovereign There is no State more rigorously bound by treaties Nevertheless a new life has been given to the doctrine by the appeal of the succession States in central Europe to the League in their attempts to coerce their minorities to respect their sovereignty The only valid sovereignty is that of the rule of law

Many attempts have been made to enumerate the attributes of sovereignty, *i e*, the regalia, prerogatives, etc., as they were called For example, Bodin gives a list of the properties of *majestas* or sovereignty. (*a*) "Legem universis, etc, singulis civibus dare posse, (*b*) bellum indicere aut pacem inire, (*c*) to appoint and change magistrates, (*d*) power of final appeal; (*e*) power of pardon, (*f*) raising revenue, (*g*) coining money" (*De republica,* vol. i ch 10) Bluntschli (*Allgemeine Staatslehre,* i 575) enumerates these attributes (*a*) right of recognition of *majestas;* (*b*) independence, (*c*) power to determine constitution; (*d*) right of legislation, (*e*) action through deposed organs, (*f*) irresponsibility These enumerations are open to the objection that they merely describe the action of the State at a particular time or indicate a theory of what an ideal State should be. *See* PROTECTORATE, SPHERES OF INFLUENCE, STATE, SUZERAINTY.

BIBLIOGRAPHY—The literature of the subject is immense, every book on political science, from the *Republic* of Plato and the *Politics* of Aristotle, has dealt with or touched sovereignty A few of the chief modern works are J. C Bluntschli, *Allgemeine Staatslehre* (Munich, 1852), J Austin, *Lectures on Jurisprudence* (3rd ed, 1869), H Maine, "Minute on the Kāthiāwār States," *Life and Speeches* (1864) and *Early History of Institutions* (1875), R. von Mohl, *Encyklopadie der Staatswissenschaften* (2nd ed, Tubingen, 1872); P. Laband, *Staatsrecht des deutschen Reiches* (Freiburg-im-Breisgau and Tübingen, 1876), G Meyer, *Lehrbuch des deutschen Staatsrechts* (Leipzig, 1878), O Gierke, *Johannes Althusius* (Breslau 1880) and *Das deutsche Genossenschaftsrecht* (1863–81), K Gareis, *Allgemeines Staatsrecht* (1882), G Jellinek, *Die Lehre von den Staatsverbindungen* (1882) and *Ueber Staatsfragmente* (1896); H Rosin, *Souveranitatstaat* (1883), A V Dicey, *Law of the Constitution* (1885, 8th ed 1915); C Salomon. *L'Occupation des Territoires sans Maîtres* (1889); T M Cooley, *Constitutional Limitations* (6th ed 1890); J. B. Westerkamp, *Staatenbund und Bundesstaat* (Leipzig, 1892), J R Green, *Works* (1892); W W Fowler, *City State of the Greeks and Romans* (1893), I Clauss, *Die Lehre von den Staatsdienstbarkeiten* (1894), K. SOVIET BANKING SYSTEM. The banking system of the U S S R was introduced with the establishment of the State Bank of the U S S R, which commenced operations on November 16th, 1921 It was for a time the only bank in the Union The reason for this was, that the civil war, the Decree of December 14th (27th), 1917, for the nationalisation of the banks, the curtailment of the money system and the exchange of commodities on a money basis, caused the old credit system to disappear

When the civil war came to an end in 1921, and the so-called "New Economic Policy" was introduced,—which, among other things, implied the restoration of the money system and the exchange of commodities on a money basis,—the Soviet Government realised the necessity for having a banking system in the country It commenced by establishing the State Bank for the operations of which, funds, in the form of the paper currency in circulation at the time, were allocated from the Treasury Soon, other credit institutions, mostly State, municipal and co-operative, began to spring up and by the middle of 1928 a number of banks of different types were in being

Of these types of banks the principal are

(a) Long term credit banks, in which are included The Industrial and Electrical Long Term Credit Bank of the U.S S R, known as the "Prombank,"—the function of which is to accumulate funds for providing long term credits for the purpose of enlarging existing and erecting new factories and works for industry and electrification, the Central Municipal and Housing Bank of the U S S R, known as the "Tsekombank,"—the function of which is to finance house building in towns and the development of municipal enterprises, and finally, the Central Agricultural Bank, —the function of which is to provide credits for agriculture

(b) Municipal Banks, operating with funds provided mostly out of local budgets Their function is to finance local industries, local housing and municipal enterprises. On July 1st, 1928, 116 such banks (incl branches) were in operation

(c) Co-operative Credit Banks, like the "Vsekobank," the "Ukrainbank" and several other banks, which provide credits for the various types of co-operative enterprises.

Counting the branches of the State Bank, and the rural banks connected with the Central Agricultural Bank, the total number of credit institutions in the U S S R on July 1st, 1928, may be put at 1,291. (In this are not included Agricultural Credit unions numbering 47 on the said date, and the smallest rural banks—so-called Agricultural Credit Societies, numbering about 9,000) In addition, there are in the U S S R 15,138 savings banks, which take deposits, but engage in no active transactions

The predominant rôle in the Soviet Banking system is played by the State Bank A year after it was established, the Government granted the Bank power to issue its own chervonetz notes In issuing these notes the State Bank took measures for the improvement of the circulation of currency Chervontsi began to be issued towards the end of 1922

By the end of 1924, the last of the depreciated Soviet roubles were withdrawn, and the depreciation of the currency, that had been going on for several years, was stopped

The State Bank issues bank-notes—chervontsi—in accordance with the Act of October 11, 1922 This Act provides for the issue of chervontsi in denominations of 1, 2, 3, 5, 10, 25 and 50 chervontsi (1 chervonetz is equal to the previous, Russian gold, ten rouble piece, *i e*, 7·74234 grammes of fine gold) The State Bank notes have a backing of precious metals and stable foreign exchange to an amount of not less than 25% of the issue

Simultaneously with the State Bank notes, other currency is

in circulation, viz., Treasury notes, in denominations, expressed in gold roubles, of 5 roubles, 3 roubles and one rouble, and also silver, copper and bronze coins, in denominations of one rouble and less. The Treasury notes and coins are not issued by the State Bank, but by the Commissariat for Finance; they are actually put into circulation, however, through the State Bank.

The total amount of money in circulation on July 1st, 1928, was 1,701·1 million roubles, of which, State Bank notes amounted to 1,019·4 million roubles; Treasury Notes 494·0 million roubles, and coins, 187·7 million roubles.

The State Bank with its 622 branches negotiated loans and discounts as follows:

	(In millions of roubles) *All Banks*	*State Bank*
1-10-1925	2,921.3	1,643.9
1-10-1926	4,066.2	2,071.1
1-10-1927	6,103.3	2,982.2
1- 7-1928	7,698.3	3,262.5

On July 1st, 1928, the State Bank advanced credits to various enterprises, in the form of loans and discounts, amounting to 3,262·5 million roubles, which represents 42·4% of the total sum advanced in similar transactions by all the banks combined.

In addition to fulfilling the functions of a bank of issue, regulating the circulation of money, and of the principal short term credit bank, the State Bank at the same time acts as the chief cashier of the Treasury, and all business connected with the State budget, in Moscow and in the provinces, is transacted through it. As a consequence, the State Bank always has available considerable sums standing to the account of the Treasury. These sums of money, its note emissions, the current accounts and deposits of other persons and institutions, and the capital of the Bank, comprise the main liabilities of the State Bank.

On July 1st, 1928 the liabilities of the State Bank were made up as follows: Capital, 365·4 million roubles; bank-notes issued, 1,046·1 million roubles; current accounts and deposits, 1,251·0 million roubles.

A part of the resources thus accumulated, the Bank places to its fund for covering bank-note issues and part is invested in securities. The greater part of these resources, however, is invested in loans and discounts. The principal clients of the State Bank who apply to it for credits are: the State trusts—in whose hands are concentrated the principal industrial enterprises of the country, such as, the coal mines, oil fields, metallurgical works, sugar, leather and textile mills, etc.; the syndicates—mainly the trading enterprises, which supply the above mentioned enterprises with raw materials and market their products; the railways; the various types of co-operative unions, and other banks. The financing of foreign trade—both imports and exports—also represents an important part of the operations of the State Bank.

The interest charged by the State Bank ranges from 8 to 10 per cent per annum. Operations are conducted in the usual form of discounting bills; opening of special current accounts against the security of bills or goods; granting fixed term loans on goods, and issuing of letters of credit against goods in pledge. A relatively small proportion of the credits are advanced in the form of loans for special purposes, *i.e.*, loans on promissory notes, usually with some additional security.

See S. S. Katzenellenbaum, *Russian Currency and Banking, 1914–24* (1925); *Soviet Union Year Book*, 1928, compiled and edited by A. H. Santalov and L. Segal. (S. S. K.)

SOVIET SYSTEM. The Soviet system was not the fruit of speculation upon the theory of representation and government. It had its origin in the daily needs of a revolutionary struggle. It was evolved to fit the political tactics of a subtle realist. It survived because it was well adapted to the requirements of the working-class dictatorship which Lenin established in Russia. Its idea has, none the less, something in common with the theoretical views held before the World War by Sorel in France, and by the Guild Socialists in England. The same tendency reappears in the Constitution of Fascist Italy. All of these systems depart from Western Democracy by grouping citizens on a functional rather than a territorial basis. Not passive residence in a given area, but the active performance of socially useful work constitutes the qualification of an elector.

The word soviet means council. In their original form, the Russian soviets were simply committees of strikers. During the general strike of 1905 an organization suited to the momentary need had to be rapidly improvised. Each factory or workshop in Moscow and Petrograd constituted a natural unit. Its workers knew each other, possessed common interests and a mass consciousness, and could easily pick leaders and representatives. Each factory chose delegates in a rough ratio to the number of its employees, and these met in a soviet which sat in permanence, and directed the strike. The revolution of 1917 repeated the same tactics, and revived the old mechanism. The Soviets, however, survived the strike, and assumed the task of controlling the weak Provisional Governments, which followed each other from March to November. They spread to the army, where each battalion chose its soviet of soldiers. They were imitated in the villages. As they spread over Russia, it was natural to link them up in congresses, which could speak for the masses of the population, workers, soldiers and peasants. It was not for any theoretical reason that Lenin preferred them to the democratic Constituent Assembly, as the organ of government after his *coup d'état*. He had a majority in the soviets, whereas his chief rivals, the Social Revolutionaries, dominated the Assembly. History had thrown up a tool admirably suited to the purposes of a working-class dictatorship. A soviet represented only the workers and peasants: the old ruling class could not influence it, or enter it. It could be elected, recalled or re-elected, with ease and without formalities, so that in a time of rapid change, it reflected the mood of the moment. What was, at the start, a method of organizing a class for a sharp political struggle, became after the *coup d'état* a machine for governing Russia.

The limitations of the soviet franchise follow inevitably from the root idea of the revolution. The purpose of the soviets is not to elicit the general will of the whole population. That for a Communist is an absurdity. One might as well talk, as Bukharin has put it, of a general will common to sheep and wolves. The purpose of the soviets is to express the will of the workers in their struggle with the *bourgeoisie*. They are councils of war, and naturally one does not permit the enemy to elect them. Every adult of either sex is a voter, from 18 years of age, with the exception of those disqualified as *bourgeois*. These latter include all employers of labour (other than domestic servants and apprentices), all who live by "speculation" (meaning private trade), or by rent or interest, certain classes identified with the old *régime* (notably priests and members of the Tsarist police), together with criminals and the insane. Brain workers (doctors, teachers, etc.) are grouped by their professions, and vote on the same terms as manual workers. Housewives are recognized as a working group, and vote in the towns in regional units. The exclusions, important in the early days of the revolution, are no longer of much consequence. About 5% of the adult population is disfranchised in the towns, and less than 1% in the villages.

The number of workers in each unit (factory, professional group, or village) determines the number of delegates to be elected. But a deliberate disparity exists between urban workers and peasants. The former were the more reliable fighting element in the class struggle. One urban *elector* has, in the higher soviets, five times the voting power of each *inhabitant* of a village. Actually the advantage is as three to one.

Only the soviets at the base of the system, those of the town and village, are directly elected. Village soviets are grouped to elect the soviet of the *volost* (parish), while the *volost* soviets elect that of the *uyézd* (county). The important unit is, as in the old days, the Gubernia (Government), and its soviet, or congress of soviets, is chosen by the soviets of the towns and *volosts* in its area. The sovereign body in each of the republics which form the Soviet Union, is a Congress of Soviets, chosen by the soviets of the "Governments" and larger cities. The Union Congress in the same way represents the congresses of the component republics. The national and federal congresses are big, unwieldy bodies (in the case of the Union including 1,500 members) which meet only

once a year for about ten days. The real legislative body is a central executive committee, which meets at least three times a year. The chief power, that is to say, resides in a body chosen indirectly at six removes from the electorate The will of the proletariat passes through a highly elaborate sieve

After 11 years, the revolution is in process, perpetually on the alert against its foes at home and abroad; there is no relaxation of the dictatorship first proclaimed in Nov 1917. For two or three years after that date certain Socialist parties, other than the ruling Communist Party, were tolerated (the Left Revolutionary Socialists and the Mensheviki or Minority Social Democrats), but even these have now ceased to exist as legal groups. The Communist Party is to-day, and for long has been, the only organized political group It alone enjoys the right of meeting; it alone may use the printing press, the wireless and the cinema, it alone may present its lists of candidates at elections. Even within this party, though informal groups exist and differences of opinion are freely debated at conferences and in the press, any organization of sectional tendencies is regarded as disloyal.

The case only becomes worse when one takes into account the tight discipline of this party, a survival from the days when it lived underground as a secret organization. It could survive only by cultivating the austerer virtues, by claiming from its adherents a devotion which over-rode all ties of business or family, and by imposing monastic vows of poverty and obedience Even to-day no member may draw more than a fixed maximum income, which in Moscow is limited to 225 roubles per month (about $112 or about £25). Entry to this party is hedged by rigid tests of character and orthodoxy, the conduct of the novice is scrutinized during a period of probation; expulsions, and even wholesale purges, on account of lack of zeal or heretical opinions, occur frequently This party has always possessed, and still nominally possesses, the democratic organization usual in all Socialist parties It elects its officers and governing committees, and decides its policy at representative conferences But, especially since the death of Lenin, its central machine, under the control of its secretary, Stalin, has attained an overgrown authority, it may even seek to nominate the officials of local branches, and to control the voting at conferences by the admission and expulsion of members.

The institution of the dictatorship means, primarily, that all important decisions of policy are made by the Communist Party, and especially by its standing political committee ("Politburo") The soviets, even those at the apex of the system, do little more than register the previous decisions of the governing party. There may be a hot and prolonged debate within the party over each new departure of policy, accompanied by frank polemics in the press But when once the final vote is taken at a party congress, it becomes binding upon every member of the party A defeated minority must sit silent, when the same topic comes before a soviet This system eliminates from the soviet apparatus any possibility of an organized opposition There are, indeed, in every soviet a number of non-party deputies, who even form the majority in the village soviets, and about half the membership of the *volost* and *uyezd soviets.* But they possess no organization, and do not challenge the established principles of the Communist *régime*

Russians have eliminated most of the issues which in other countries form the material of politics There is no standing clericalist controversy, as in France, no dispute over the limits of *laissez-faire,* as in Great Britain, no division over high and low tariffs, as in the United States. Politics in Russia, apart from foreign questions, mean the supervision of the socialized industries, the measures to be taken for the development of agriculture, the accumulation of a surplus for the purchase of machinery abroad, the promotion of public health and education, and, above all, the tactics best adapted to neutralize the indifference of the peasants towards the purposes of a Socialist State If a soviet was, in its origins, a council of officers conducting the class-war, it is to-day a board meeting of the directors of a complicated industrial apparatus

The characteristic franchise on which the soviets rest is not in fact, their chief distinction They differ from other representative bodies mainly in this, that no sharp distinction exists between legislative, administrative and judicial functions. There is no covenanted civil service, though every soviet engages its clerks and even its experts. Nor is there any independent judiciary judges are named by the soviets, and the appointments are frankly political. Every soviet, whether national or municipal, groups itself, after each annual election, into standing sub-committees, each entrusted with some branch of the administration. Each member specializes, and finds congenial work in inspecting and supervising the work of schools, hospitals and other public institutions, or in watching the administration of the Labour Code In a country which had only the most meagre tradition of self-government, the soviets have performed an inestimable service by educating large numbers of the working-class in the details of public administration Of recent years it has been the policy of the Communist Party to favour the election each year of as large a number as possible of new members of the soviets, in order to spread this experience widely, and to win intelligent support for its work Its watchword is now "to broaden the base of the dictatorship"

A soviet election involves the minimum of public controversy The Communist Party will issue a manifesto outlining the results of the past year's work and its plans for the future But there can be no reply from any organized opposition Old members who are standing again publish in the newspaper of the factory an account of their personal work and achievements In each factory preliminary group meetings are held, at which the candidates are questioned. Finally the elected works council of the factory draws up an official list of candidates This is submitted to a general meeting of all the employees of the concern Alternate nominations are invited, as a matter of form, but are rarely, if ever, forthcoming After some platform oratory, while the band plays the *Internationale*, the list is adopted *en bloc* by a show of hands The procedure has only the most distant resemblance to an election as democratic countries understand that word it is, in fact, an organized demonstration of unanimity The list will always be one acceptable to the local Communist Party, though it will always include a large proportion of non-members.

Unofficial opinion finds some little expression in proposing resolutions at these election meetings, which, if carried, become the mandates of the deputies In the villages there is often a sharp contest, in which the richer peasants oppose the poorer and "middle" peasants, who are more disposed to accept Communism

The vast territory which the world knows as Russia (the component republics are the Russian Federation, Transcaucasia, Ukraine, White Russia, Uzbekistan and Turkmenistan; the two first of these are themselves federations) is governed under a Federal Constitution, which admits the right to secede It would be unworkable, were it not that one tightly-disciplined party exists, which prescribes general principles, checks any tendency to particularism, and settles the controversies over jurisdiction to which the loosely-drafted Constitution often gives rise The Communist Party supplies the place of a ruling race, or of the trained bureaucracy of the old *régime*, and is the cement which holds together Great Russians and Little Russians, Tatars, Georgians and Turcomans, Christians, Jews and Muslims In its distribution of powers the Soviet Union is the most highly centralized federation in the world But in its attitude towards the many languages and cultures of its territory, it has shown an admirable liberality. Wherever a non-Russian race occupied a compact area, an autonomous republic or territory was created This was done not only for peoples of equal culture, like the Ukrainians or the Germans of the Volga, but also for depressed races like the Tatars and the Bashkirs, who possessed neither schools nor a vernacular literature before the Revolution. To such races the new era has brought, for the first time, complete equality with the Great Russians, and ample opportunity for the development of their native culture and language But every racial minority, *e.g.*, a Polish or Jewish village in White Russian or Ukrainian territory, enjoys the full right to use its own language in its schools

The Union of Socialist Soviet Republics deliberately erased the word "Russian" from its official title because it is regarded as a

Socialist League of Nations, the nucleus of a world-wide federation. To the Union are reserved five departments: (1) foreign affairs, (2) defence, (3) foreign trade, (4) transport, (5) posts and telegraphs. Next come five departments over which the Union exercises control, and lays down general principles, while it leaves to the component republics the detailed administration and some initiative in legislation. These are (1) labour, (2) finance, (3) workers' and peasants' inspection (a department of audit), (4) internal trade, and (5) the Supreme Council of Public Economy. Finally, there are six departments in which the Republics enjoy complete autonomy: (1) agriculture, (2) home affairs, (3) justice, (4) education, (5) health, (6) social welfare.

The administration of each of these departments, alike in the Union and in the Republics, is placed under a "Commissariat," which differs little from the Western conception of a Ministry. The commissar is, however, usually the chairman of a small board, or "collegium," which meets daily and takes its decisions in common. The Council of Commissars acts as a cabinet, and has, in the intervals between the sittings of the executive of the Congress of Soviets, the right to issue emergency decrees and legislation. Of these commissariats the most important in a socialized State is, of course, the Supreme Council of Public Economy, which coordinates the relations of the productive "trusts" (*i.e.,* the nationalized industries), the distributive "syndicates" (which sell their product), fixes the level of prices, and, in the last resort, determines what proportion of the profit shall be set aside as new capital, and what proportion shall be assigned to raise wages. But the most characteristic institution is the central planning department (Gosplan) which collects statistics, estimates output, and works out schemes for the expansion of industry, the exploitation of raw materials, and the development of electric power.

Lastly, it should be explained that the sovereign body of the Union, which must finally pass or ratify legislation, is a two-chambered institution. On the Council of Nationalities, in effect a Senate, each autonomous republic and territory has a single representative, and little Tatary counts for as much as Great Russia. It deals with the cultural rights of the nationalities. To the other chamber, known as the Central Executive Committee, the cabinet (Council of Commissars) is responsible, and is elected by it. The assent of both chambers is theoretically required for legislation. No provision exists for conflicts between them, since both are equally emanations of the ruling Communist Party.

It is not easy to determine how much this soviet system, regarded as a constitutional experiment, contributes to the stability of the Communist *régime.* It rests on the support of the urban working-class, which feels itself the privileged ruler of the State. It has, that is to say, the assent of that part of the population which is strategically important, for the industrial area is the centre of Russia, and of its network of communications.

The peasants are, passively acquiescent, preferring Communist rule to any visible alternative, since it has given them the land. Though real wages are low (with an index figure of 50 as against 100 in London and 40 in Warsaw) and housing conditions bad, the workers unquestionably have the sense that their whole environment is ordered for their good. No privileged class stands above them. Every career, including the professions and the officers' corps of the Red army, stands wide open to them. The entire educational system is devised for their benefit. The clubs, schools, crêches and playing fields grouped round every factory, offer them an active social life, which they themselves direct. Of all this the soviets are the natural political expression. They are based on the factory itself. The immense majority in every soviet, and even in their executive committees, is composed of manual workers.

The indirect method by which the higher soviets are chosen is, on the other hand, open to grave criticism. It would give the rank-and-file of the electorate only a weak and diluted influence over the larger issues of public policy, even if elections were free. As things stand to-day, the only guarantee that the will, even of the urban masses, shall prevail, lies in the anxiety of the Communist Party to keep their support. Though it retains its dictatorship, its attitude has perceptibly changed since the early years. It has its ear to the ground. It talks of itself as the mouthpiece of the masses. It has developed an elaborate system by which it receives a continuous stream of reports from every factory and village in Russia, on the trend of popular opinion, on grievances large and small, and on the defects of legislative drafts under the consideration of the soviets. The absence of individual liberty and civil rights is not resented by the workers, as it would be in the West, partly because Russia has had no experience of freedom, and partly because the dictatorship is exercised by workers for the workers' benefit. The gravest evil of the actual system—that it tolerates no opposition, and permits the criticism only of persons and of details—is inherent rather in the Communist dictatorship than in the soviet idea. That idea undoubtedly appeals to Russians as a native growth, a product of their own experience and history. Its obvious merits, in the first stages of election, are patent to the simplest citizen. Its graver defects, in the later stages, do not come under his observation. He accepts it as a racy and original form of democracy, while only the "intelligentsia" has the knowledge to contrast it with Western practice and theory. (H. N. Br.)

Bibliography.—An ample technical literature in the Russian language expounds the rapidly developing Soviet constitution. For the non-Russian reader, the clearest and frankest statement of the ideas that underlie it is Bukharin's *ABC of Communism.* A useful account of its provisions in its earlier phase is Andrew Rothstein's *The Soviet Constitution. How the Soviets Work* (Vanguard Press) by H. N. Brailsford is an attempt to describe the working of the system.

SOVIET TRADE ORGANIZATIONS. The control and conduct of the foreign trade of the U.S.S.R. are carried out by *Narcomtorg* (the People's Commissariat for Trade) and its local branches. Trade Delegations have been set up in all countries with which the U.S.S.R. has diplomatic relations.

The entire foreign trade of the Soviet Union as regards the quantity and quality of goods to be exported or imported is regulated by the plans drawn up for each year by *Narcomtorg,* and which are ratified by the Council for Labour and Defence in consonance with the State Planning Commission. *Narcomtorg* and the Trade Delegations abroad supervise and control purchases and sales from the point of view of the legality of the transactions, their commercial advantage, and their concordance with the foreign trade policy of the Government and the export-import plan laid down.

Anglo-Soviet Trade.—The trading relations between Great Britain and the U.S.S.R., which had broken down during the war, revolution and blockade, began gradually to be restored in 1920, after the decision of the Inter-Allied Supreme Council at Paris on January 16th, 1920, to raise the blockade against Soviet Russia. The actual resumption of trade dates from June 1920, and the first organization to carry out such trade was Arcos, Ltd., established in 1920. A trade agreement was concluded between Great Britain and the U.S.S.R. on March 16th, 1921, which was terminated by the British Government in May 1927.

The foreign trade of the U.S.S.R. being a State monopoly can be conducted only by organizations specially authorized to perform export and import operations. The organizations conducting the foreign trade of the U.S.S.R. in Great Britain are registered under and subject to British jurisdiction.

According to the functions performed by the different organizations, they can be classed in the following groups: (1) trading organizations; (2) merchant shipping organizations; (3) insurance organizations; (4) banks; (5) representatives of various trading and industrial organizations of the U.S.S.R.

The trading organizations also fall into the three following groups:

(A) Limited liability companies with Soviet capital;
(B) Mixed companies with Soviet and foreign capital;
(C) Co-operative organizations with Soviet capital.

To group (A) belong: (a) Arcos, Ltd., purchasing and selling agency for the principal exporting and importing organizations in the U.S.S.R. Paid-up capital £900,000. (b) Russian Oil Products, Ltd., sole agents for Great Britain and Ireland of the Naphtha Syndicate of the U.S.S.R. Paid-up capital £100,000. (c) White Sea Timber Trust, Ltd. (paid-up capital £100,000),

Russhollandless, Ltd (share capital £150,000), and Russangloless, Ltd. (share capital £150,000), agents for the sale in Great Britain of Russian timber and timber products (d) Kniga (England), Ltd, exporters from Great Britain of books, periodicals, stationery, etc Share capital £3,000 (fully paid) (g) Mosekust (Russian Handicrafts), Ltd, importers of Russian lace, carpets, ivory, toys, china, etc Share capital £100

To the group (B) belong (a) The Russo-British Grain Export Co, Ltd, sole selling agents in Great Britain and Ireland for the Corn Export Company, *Exportkhleb*, Moscow, importers of Russian grain, seeds, oilcakes, offals, vegetable oils, etc Share capital £200,000 (fully paid) (b) Russian Wood Agency, Ltd, agents for the sale of Russian timber materials on behalf of Exportless, Severoless, Sevsapless, Karelless and other Russian timber trusts Share capital £240,000 (fully paid), Dvinoless Export, Ltd (share capital £100,000, fully paid), and Russnorvegoless, Ltd. (registered as a Norwegian limited liability company, with a share capital of £300,000), importers of Russian timber materials

To group (C) belong. (a) Centrosojus (England), Ltd, agents in Great Britain and Ireland for the Central Union of Russian Consumers' Co-operative Societies, *Centrosoyúz,* Moscow, and for other co-operative unions in the U S S R Share capital £250,000 (fully paid) (b) Selskosoyúz, Ltd, agents in Great Britain for the various agricultural co-operative unions. Share capital £50,000 (fully paid) (c) Ukrainian Co-operatives, Ltd, representatives in Great Britain of the Ukrainian Co-operative Societies Paid-up capital £21,000 (d) Central Association of Flax Growers, Ltd, sole representatives of Exportlen, Ltd, Moscow; importers from the U S S R of flax, tow and hemp Capital £44,750.

The only merchant shipping organization is the Anglo-Soviet Shipping Co, Ltd, the loading brokers and agents for the Soviet Mercantile Fleet, *Sovtorgflot* Share capital £1,000 (fully paid) The only insurance organization is the Black Sea and Baltic General Insurance Co, Ltd, which are the London correspondents of the U S S R, State Insurance Department, *Gosstrakh* Share capital £100,000 There are two banks The Moscow Narodny Bank, Ltd (paid-up capital £750,000) finances the foreign trade of co-operative organizations The Bank for Russian Trade, Ltd (paid-up capital £550,000) finances Russian trade with Great Britain other than co-operative trade Finally, there are in Great Britain representatives of the U S S R State Bank; and of *Gostorg*, *Ukrgostorg*, and *Zakgostorg*, which are the State import and export trading offices of Russia, of the Ukraine, and of Transcaucasia respectively

The Extent of Anglo-Soviet Trade.—During the eight years from the renewal of trade between Great Britain and the U S S R in June 1920, to the end of June 1928, the total turnover of Anglo-Soviet trade amounted to £216,649,000 The following table shows the actual figures of sales and purchases of the Soviet trading organizations in Great Britain Sales are goods invoiced to buyers, c i f British ports Purchases are orders placed with British firms, f o b British ports

Year	Soviet sales in Great Britain	Soviet purchases in Great Britain
	£	£
1920		2,810,000
1921	1,866,000	7,281,000
1922	5,933,000	9,433,000
1923	10,458,000	4,659,000
1924	19,444,000	14,801,000
1925	26,908,000	31,171,000
1926	23,617,000	13,440,000
1927	23,302,000	10,140,000
1928	24,198,000	6,375,000
Grand total for whole period	119,831,000	96,818,000

The principal articles purchased in Great Britain during the whole period consisted of: cotton, £16,226,000; grain, £11,235,000; various machinery, £12,114,000; wool and wool yarn, £8,587,000; rubber, £7,817,000; hides and skins, £6,281,000; tea, coffee and cocoa, £5,833,000, chemicals, £5,264,000, fabrics, £4,132,000. The principal Soviet sales in Great Britain during the eight years were timber materials, £37,818,000; furs, £18,961,000; wheat and other grain products, £17,775,000; oil products £19,193,000, butter, £11,700,000, flax, hemp and tow, £8,455,000. There was a big decline in trade after the break of diplomatic relations between the two countries in May 1927

Soviet-American Trade.—Trade between the U S S R and the United States is now conducted by the following four organizations with headquarters in New York The Amtorg Trading Corporation, the All-Union Textile Syndicate, Inc ; Centrosoyus, Inc ; and Selskosoyúz, Inc In addition to these, a number of concessionaire firms export from the Soviet Union

The Amtorg is an extensive import and export organization trading in every kind of commodity with the exception of cotton and wool The All-Union Textile Syndicate is purchasing in the United States machinery and raw materials for the textile industry of the U S S R. Centrosoyus sells on the American market goods imported from the Consumers' Co-operative Societies of the U S S R, chiefly furs, flax, and hemp, and purchases for the same bodies various goods for consumption and for office equipment Selskosoyus is selling on the American market goods imported from the agricultural co-operatives of the U S S R, and purchases in the United States agricultural machinery and equipment tractors, and so on The figures are

Year	Soviet sales in the United States	Soviet purchases in the United States
1913–14	$23,294,000	$31,557,000
1922–23	2,705,000	
1923–24	5,492,000	43,917,000
1924–25	11,307,000	86,939,000
1925–26	30,649,000	47,018,000
1926–27	20,252,000	72,850,000
1927–28 (preliminary)	25,000,000	95,000,000

The principal commodities sold in the United States in 1926–27 were furs, $9,763,000; manganese, $1,351,000; flax, tow, etc, $1,112,000 Cotton is the principal article purchased by the U S S R from the United States, in the first nine months of 1927–8, Soviet purchases of cotton in America amounted to $60,608,000 In the same period orders for machinery and equipment amounted to $10,000,000 Next in importance came agricultural machinery, tractors, and motor transport. (L Se)

SOWERBY, JAMES (1757–1822), English natural-history artist, was born in London on March 21, 1757 He became a student at the Royal Academy, and subsequently taught drawing, but turned to the illustration of botanical and conchological works, and published *English Botany* (36 vols, 1790–1814), and *British Mineralogy* (5 vols, 1804–1817) He planned and partly carried out *The Mineral Conchology of Great Britain* (7 vols, 1812–1846), concluded after his death by his sons

SOWING, in agriculture, the planting of seed for the raising of crops The scattering of seed by hand is the simplest and oldest method

The seed must not fall more thickly at one point of the cast than at another, and the standard of seeding per acre must be rigidly adhered to, hence manual-sowing demands considerable skill and experience It is still preferred in some districts for the sowing of corn crops; and in some cases the plough is followed by a furrow-presser, the seed falling into the "nicks" made by it, though under ordinary circumstances the face of the field as left in "seams" by the furrow-slices from the plough is in a suitable condition for broadcasting So well, indeed, is the ploughing done in many countries that broadcasting gives perfectly good results, and broadcasting machines reaching up to 15ft wide are in common use in place of hand-sowing, as these get over the ground more quickly and deposit the seed more regularly.

As early as 1662 a sowing-machine was invented by Joseph Locatelli in Carinthia In England the early history of mechanical sowing is chiefly connected with the name of Jethro Tull, who about 1730 invented the corn-drill Cooke's drill brought out in 1783 was the definite precursor of the modern drill The drill,

besides depositing the seed at a uniform depth, sows it in parallel rows at equal distances from one another and thus makes possible the use of the horse hoe and facilitates the suppression of weeds amongst growing crops, the latter advantage being specially marked in the case of root crops. The "cup-feed" and the "force-feed" are the commonest and most generally useful types. The cup-drill consists of a long box carried upon wheels and divided diagonally into two sections by a partition. The forward section contains the seed which drops through apertures, the size of which can be regulated by slides, to the bottom section. A spindle geared to the ground-wheels by cogs passes longitudinally through the centre of this section and carries disks, round the rims of which are fitted small cups. As the horses pull the drill forward, the spindle and disks revolve and the cups scoop up the seed and pour it into the funnels; thence it proceeds down a series of tubes or "spouts" and drops into shallow furrows traced by small coulters travelling immediately in front of the streams of seed. The coulters can be raised or lowered by levers and are kept down to their work by weights or pressers, which can be regulated according as deep or shallow sowing is required.

In the force-feed type of drill the seed falls through apertures in the bottom of the seed-hopper into funnels, through which extends a shaft carrying bowl-shaped wheels, one for each. These wheels are either spirally-grooved inside or else cogged and serve to feed the seed regularly into the funnels. Instead of coulters, the drill is often fitted with shoes or revolving disks, similar in action to those of the disk-harrow. The tooth and brush pinion, the perforated disk and the chain feed drills, are other types differentiated according to the method by which the seed is "fed" from the hopper and the kind of crop being sown.

Liquid-manure drills distribute chemical manure mixed with water and are often fitted with a seed-box for root seeds, the manure and the seed being deposited through the same spout. Drills are also made in which dry fertilizers may be deposited with the seed in a similar manner.

The wheelbarrow seeder, a long box pierced with openings and carried transversely on a skeleton wheelbarrow, is used for sowing grass seed.

The Maize Lister.—In the United States the maize or Indian-corn crop exceeds all others in value, and machines used in planting and handling this crop are of great importance. Corn (maize) is sometimes "listed" or planted in a continuous row like wheat, and for this purpose a machine known as a lister is employed.

In its general construction this machine is a sulky plough, having a double mould-board, which turns the furrow in both directions. Immediately behind the plough is a sub-soiler for deepening the furrow and penetrating to the moist soil below the surface. A seed-box is mounted on the plough beam, and is provided with a feed-plate operated by a shaft geared to one of the wheels. The seed is delivered to the furrow in rear of the mould-boards and covered by two shovels fixed behind which turn the soil back into the furrow.

The Corn Planter.—Maize, however, is commonly planted in equally spaced "hills," which form rows at right angles to each other, so that a cultivator may be driven through them both lengthwise and crosswise of the field. This work is usually done by a machine called a check-row corn planter.

In using the corn planter, a wire, having buttons attached thereto, at intervals corresponding to the distance between the hills, is first stretched across the field and anchored at its ends. This wire is then placed upon the guide rollers at the side of the machine and passes between the jaws of a forked lever, which is connected at its other end with a rocking shaft passing across the machine and serving to oscillate a feed-plate in the bottom of each seed-hopper. As the buttons on the check-wire strike the forked lever, the latter is drawn to the rear and causes the feed-plate to drop the seed through the tubes into the open space between the plates of the furrowing shoe. A reel at the rear of the machine is used to take up the check-wire as the planter progresses. (P. McC.)

SOYA BEAN, also known as the soja bean and in the United States as the soy bean, is a leguminous plant native to southeastern Asia. It has been cultivated in China and Japan since long before written records were kept, and from the standpoint of uses and value is the most important legume now grown in those countries. Although limited acreages are grown in Italy, France, southern Russia, Hawaii, Egypt, South Africa and in a few countries of South America, its culture at present is largely confined to China, Manchuria, Japan, Chosen (Korea) and the United States. It is also more or less important in India, Indo China and the Malayan islands.

Although first introduced into the United States in 1804, the soy bean has become important only during the last 10 or 15 years. Only eight varieties were grown in 1898, whereas at present more than 60 varieties are handled by growers and seedsmen. Previous to 1917, the soy bean acreage was less than 500,000, but by 1924 it had increased to 2,500,000. The soy bean can be grown in any climate suitable to maize or cotton, and the crop is now grown generally over the eastern half of the United States. Recent increases in acreage have been most marked in the maize belt and some of the Southern States. Introduction and breeding of improved varieties have extended the culture of the crop far beyond what were first considered its limits of profitable production, and it is destined to become a crop of great economic importance in the United States. Its principal uses are hay, pasture, silage, oil and oil meal, and human food (*see* SOYA BEAN OIL). It can be used advantageously, either as a seed crop or a forage crop, in many systems of rotation; also as a catch crop where new seedings of grass or clover have failed. In combinations with other crops, such as corn, cow-peas, Sudan grass or sorghums, it furnishes a well-balanced ration for live stock, a large yield and a great variety of forage. The seed is rich in oil which makes the crop an important source of vegetable oil, and the resultant residue makes a highly concentrated and nutritious feed relished by all kinds of live stock.

Cultivation.—The growing of soy beans is easy when ordinary precautions are followed in preparing the soil and selecting suitable varieties. Where they have not been grown previously it is advisable to inoculate the soil with sweet clover or alfalfa. The use of fertilizer is recommended in sandy soil or in soils of low fertility. Seeding is usually done with an ordinary grain drill, the rows being spaced far enough apart to allow for cultivation when the crop is grown for seed. Indian corn planters are used when planting with maize, most modern planters having special attachments for the soy bean seed to permit planting in the hill or row with the maize. (L. S. R.)

SOYA BEAN OIL. An oil also known as "Bean Oil," obtained from the seeds of the leguminous plant *Soja* (*Glycine*) *hispida,* which is extensively cultivated in the Far East, where for centuries the oil and the expressed cake have been used as food.

The oil is obtained by expressing the ground seed in Anglo-American presses (*see* COCONUT OIL AND COPRA). The beans, which contain from 18% to 20% of oil, yield by expression on the practical scale about 13%. Damaged seeds are extracted with a volatile solvent, whereby almost all the oil is recovered. The expressed meal is valued for its albumenoid content, and is especially suitable for feeding to dairy cattle, causing an increase in the secretion of milk fat. The oil expressed from sound seed is pale yellow in colour and only needs filtering over fuller's earth to be fit for edible purposes. Soya bean oil contains up to 6% of linolenic acid and therefore falls into the class of drying oils. In addition to its use as an edible oil, it finds extensive employment for soap-making; boiled with a cobalt dryer it is used in the United States for the manufacture of paints.

In 1926 there were exported from Manchuria 1,423,000 tons of beans and 165,000 tons of oil. Great Britain imported 46,000 tons of beans and 43,000 tons of oil, while Germany consumed 370,000 tons of beans and 20,000 tons of oil. (E. L.; G. H. W.)

SOZOMEN, the name of a famous 5th-century church historian. Hermias Salamanes (Salaminius) Sozomenus (*c.* 400–443) came of a wealthy family of Palestine. He tells us that he was brought up under monkish influences. After studying law in Beirūt he settled down as an advocate in Constantinople, where he wrote his Ἐκκλησιαστικὴ Ἱστορία about the year 440. The nine

books begin with Constantine (323) and come down to the death of Honorius (423). The work, dedicated to Theodosius II, has reached us only in a mutilated condition, at least half a book being wanting It is a plagiarism of the ecclesiastical historian Socrates (*q v*), but Sozomen has referred to the principal sources used by Socrates (Rufinus, Eusebius, Athanasius, Sabinus, the collections of epistles, Palladius), and has not unfrequently supplemented Socrates from them The whole of the ninth book is drawn from Olympiodorus Sozomen wished to present a picture in which monasticism should be brought into still stronger prominence

Sozomen also wrote an *Epitome of History* from the Ascension of Christ to the defeat of Licinius (323) which is not now extant (*See* his *History*, i 1)

For bibliography *see* the article on the church historian, SOCRATES. Most of the editions and discussions named there cover Sozomen as well (the volume of Hussey's edition containing Sozomen appeared in 1860) The latest English translation, revised by Hartranft, is published in the Nicene and Post-Nicene Fathers, 2nd series, vol ii In addition *see* Nolte in the *Tubing Quartalschr* (1861), p 417 *sqq*; C de Boor, "Zur Kenntniss der Handschriften der Griech Kirchenhistoriker," in *Zeitschrift fur Kirchengeschichte*, vi 478 *sqq.*; Sarrazin, "De Sozomeni historia num integra sit," in the *Commentationes philologae jenenses*, i 165 *sqq*; Rosenstein, "Krit Untersuchungen uber d Verhaltniss zwischen Olympiodor, Zosimus und Sozomen," in *Forsch z deutschen Gesch*, vol i, Batiffol, "Sozomène et Sabinos," in *Byzant Zeitschr* vii 265 *sqq*

SPA, a town in the province of Liége, Belgium, less than 20 m S E of Liége, famous for mineral springs first discovered in 1326 They are supposed to have given the common name of "spa" to such resorts The town is 850 ft above sea-level In the 18th century it was the most fashionable resort in Europe for the medicinal use of such waters In 1807 much of the town was burned down, while the principal buildings, the Casino and the Pouhon, are quite modern Spa still attracts about 20,000 visitors annually Pop (1925), 8,320

SPA, CONFERENCE OF (July 5–16, 1920) This was the first occasion after the World War of 1914–18 on which the heads of the German and Allied Governments negotiated on a formal footing of equality The crucial questions at issue were the execution of the disarmament clauses and the coal delivery clauses of the Treaty of Versailles, and in both cases the Germans were compelled to sign protocols dictated by the Allies under threat of military sanctions which were set out in the documents, and included an eventual Allied occupation of the Ruhr basin

A German proposal for the general settlement of the reparation problem was rejected, but no general Allied counter-proposal was put forward An inter-Allied agreement was made for the allocation of prospective German payments, an agreement which has since been modified in detail, but which still governs the situation It was provided that France should receive 52% of sums obtained from Germany, the British Empire 22%, Italy 10% and Belgium 8%, while the remaining 8% was to be divided between the other Allied Powers By a subsequent agreement among the several members of the British Commonwealth 86 85% of the British Empire's share was allocated to Great Britain Another article in the Spa Agreement provided for the allocation of reparation payments from Austria, Bulgaria and Hungary, and "cost of liberation" payments from Italy, Czechoslovakia, Rumania and Yugoslavia At this conference the Supreme Council (*q v*) also came to an agreement with Germany for the trial of war criminals (*See* REPARATIONS)

SPACE-TIME. The Theory of Relativity has brought about a fundamental change in the scientific conception of space and time, described in a famous saying of Minkowski—"From henceforth space in itself and time in itself sink to mere shadows, and only a kind of union of the two preserves an independent existence." This union, called "space-time," is the subject of the present article As the conceptions are of considerable difficulty, most readers will probably find it best to read first the article RELATIVITY for a more elementary introduction to the subject

All our thoughts and concepts are called up by sense-experiences and have a meaning only in reference to these sense-experiences. On the other hand, however, they are products of the spontaneous activity of our minds; they are thus in no wise logical consequences of the contents of these sense-experiences If, therefore, we wish to grasp the essence of a complex of abstract notions we must for the one part investigate the mutual relationships between the concepts and the assertions made about them, for the other, we must investigate how they are related to the experiences

So far as the way is concerned in which concepts are connected with one another and with the experiences there is no difference of principle between the concept-systems of science and those of daily life The concept-systems of science have grown out of those of daily life and have been modified and completed according to the objects and purposes of the science in question

The more universal a concept is the more frequently it enters into our thinking, and the more indirect its relation to sense-experience, the more difficult it is for us to comprehend its meaning, this is particularly the case with pre-scientific concepts that we have been accustomed to use since childhood Consider the concepts referred to in the words "where," "when," "why," "being," to the elucidation of which innumerable volumes of philosophy have been devoted We fare no better in our speculations than a fish which should strive to become clear as to what is water

SPACE

In the present article we are concerned with the meaning of "where," that is, of space It appears that there is no quality contained in our individual primitive sense-experiences that may be designated as spatial Rather, what is spatial appears to be a sort of order of the material objects of experience The concept "material object" must therefore be available if concepts concerning space are to be possible It is the logically primary concept This is easily seen if we analyse the spatial concepts for example, "next to," "touch," and so forth, that is, if we strive to become aware of their equivalents in experience The concept "object" is a means of taking into account the persistence in time or the continuity, respectively, of certain groups of experience-complexes The existence of objects is thus of a conceptual nature, and the meaning of the concepts of objects depends wholly on their being connected (intuitively) with groups of elementary sense-experiences This connection is the basis of the illusion which makes primitive experience appear to inform us directly about the relation of material bodies (which exist, after all, only in so far as they are thought)

In the sense thus indicated we have (the indirect) experience of the contact of two bodies We need do no more than call attention to this, as we gain nothing for our present purpose by singling out the individual experiences to which this assertion alludes Many bodies can be brought into permanent contact with one another in manifold ways We speak in this sense of the position-relationships of bodies (*Lagenbeziehungen*) The general laws of such position-relationships are essentially the concern of geometry This holds, at least, if we do not wish to restrict ourselves to regarding the propositions that occur in this branch of knowledge merely as relationships between empty words that have been set up according to certain principles

Pre-scientific Thought.—Now, what is the meaning of the concept "space" which we also encounter in pre-scientific thought? The concept of space in pre-scientific thought is characterized by the sentence. "we can think away things but not the space which they occupy" It is as if, without having had experience of any sort, we had a concept, nay even a presentation, of space and as if we ordered our sense-experiences with the help of this concept, present *a priori* On the other hand, space appears as a physical reality, as a thing which exists independently of our thought, like material objects Under the influence of this view of space the fundamental concepts of geometry. the point, the straight line, the plane, were even regarded as having a self-evident character The fundamental principles that deal with these configurations were regarded as being necessarily valid and as having at the same time an objective content No scruples were felt about ascribing an objective meaning to such statements as "three empirically given bodies (practically infinitely small) lie on one straight line," without demanding a physical definition for such an assertion This blind faith in evidence and in the immediately

real meaning of the concepts and propositions of geometry became uncertain only after non-Euclidean geometry had been introduced.

Reference to the Earth.—If we start from the view that all spatial concepts are related to contact-experiences of solid bodies, it is easy to understand how the concept "space" originated, namely, how a thing independent of bodies and yet embodying their position-possibilities (*Lagerungsmöglichkeiten*) was posited. If we have a system of bodies in contact and at rest relatively to one another, some can be replaced by others. This property of allowing substitution is interpreted as "available space." Space denotes the property in virtue of which rigid bodies can occupy different positions. The view that space is something with a unity of its own is perhaps due to the circumstance that in pre-scientific thought all positions of bodies were referred to one body (reference body), namely the earth. In scientific thought the earth is represented by the co-ordinate system. The assertion that it would be possible to place an unlimited number of bodies next to one another denotes that space is infinite. In pre-scientific thought the concepts "space" and "time" and "body of reference" are scarcely differentiated at all. A place or point in space is always taken to mean a material point on a body of reference.

Euclidean Geometry.—If we consider Euclidean geometry we clearly discern that it refers to the laws regulating the positions of rigid bodies. It turns to account the ingenious thought of tracing back all relations concerning bodies and their relative positions to the very simple concept "distance" (*Strecke*). Distance denotes a rigid body on which two material points (marks) have been specified. The concept of the equality of distances (and angles) refers to experiments involving coincidences; the same remarks apply to the theorems on congruence. Now, Euclidean geometry, in the form in which it has been handed down to us from Euclid, uses the fundamental concepts "straight line" and "plane" which do not appear to correspond, or at any rate, not so directly, with experiences concerning the position of rigid bodies. (On this it must be remarked that the concept of the straight line may be reduced to that of the distance. A hint of this is contained in the theorem: "the straight line is the shortest connection between two points." This theorem served well as a definition of the straight line, although the definition played no part in the logical texture of the deductions.) Moreover, geometricians were less concerned with bringing out the relation of their fundamental concepts to experience than with deducing logically the geometrical propositions from a few axioms enunciated at the outset.

Let us outline briefly how perhaps the basis of Euclidean geometry may be gained from the concepts of distance. We start from the equality of distances (axiom of the equality of distances). Suppose that of two unequal distances one is always greater than the other. The same axioms are to hold for the inequality of distances as hold for the inequality of numbers. Three distances $\overline{AB'}$, $\overline{BC'}$, $\overline{CA'}$ may, if CA' be suitably chosen, have their marks BB', CC', AA' superposed on one another in such a way that a triangle ABC results. The distance CA' has an upper limit for which this construction is still just possible. The points A, (BB') and C then lie in a "straight line" (definition). This leads to the concepts: producing a distance by an amount equal to itself; dividing a distance into equal parts; expressing a distance in terms of a number by means of a measuring-rod (definition of the space-interval between two points).

When the concept of the interval between two points or the length of a distance has been gained in this way we require only the following axiom (Pythagoras' theorem) in order to arrive at Euclidean geometry analytically. To every point of space (body of reference) three numbers (co-ordinates) x, y, z may be assigned—and conversely—in such a way that for each pair of points A (x_1, y_1, z_1) and B (x_2, y_2, z_2) the theorem holds:

$$\text{measure-number } AB=\sqrt{(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2}.$$

All further concepts and propositions of Euclidean geometry can then be built up purely logically on this basis, in particular also the propositions about the straight line and the plane. These remarks are not, of course, intended to replace the strictly axiomatic construction of Euclidean geometry. We merely wish to indicate plausibly how all conceptions of geometry may be traced back to that of distance. We might equally well have epitomised the whole basis of Euclidean geometry in the last theorem above. The relation to the foundations of experience would then be furnished by means of a supplementary theorem. The co-ordinate may and *must* be chosen so that two pairs of points separated by equal intervals, as calculated by the help of Pythagoras' theorem, may be made to coincide with one and the same suitably chosen distance (on a solid). The concepts and propositions of Euclidean geometry may be derived from Pythagoras' proposition without the introduction of rigid bodies; but these concepts and propositions would not then have contents that could be tested. They are not "true" propositions but only logically correct propositions of purely formal content.

Difficulties.—A serious difficulty is encountered in the above represented interpretation of geometry in that the rigid body of experience does not correspond *exactly* with the geometrical body. There are no absolutely definite marks and; moreover, temperature, pressure and other circumstances modify the laws relating to position. It is also to be recollected that the structural constituents of matter (such as atom and electron, *q.v.*) assumed by physics are not in principle commensurate with rigid bodies, but that nevertheless the concepts of geometry are applied to them and to their parts. For this reason consistent thinkers have been disinclined to allow real contents of facts (*reale Tatsachenbestände*) to correspond to geometry alone. They considered it preferable to allow the content of experience (*Erfahrungsbestände*) to correspond to geometry and physics conjointly.

This view is certainly less open to attack than the one represented above; as opposed to the atomic theory it is the only one that can be consistently carried through. Nevertheless it would not be advisable to give up the first view, from which geometry derives its origin. This connection is essentially founded on the belief that the ideal rigid body is an abstraction that is well rooted in the laws of nature.

Foundations of Geometry.—We come now to the question: what is *a priori* certain or necessary, respectively in geometry (doctrine of space) or its foundations? Formerly we thought everything; nowadays we think—nothing. Already the distance-concept is logically arbitrary; there need be no things that correspond to it, even approximately. Something similar may be said of the concepts straight line, plane, of three-dimensionality and of the validity of Pythagoras' theorem. Even the continuum-doctrine is in no wise given with the nature of human thought, so that from the epistomological point of view no greater authority attaches to the purely topological relations than to the others.

Earlier Physical Concepts.—We have yet to deal with those modifications in the space-concept which have accompanied the advent of the theory of relativity. For this purpose we must consider the space-concept of the earlier physics from a point of view different from that above. If we apply the theorem of Pythagoras to infinitely near points, it reads

$$ds^2=dx^2+dy^2+dz^2,$$

where ds denotes the measurable interval between them. For an empirically-given ds the co-ordinate system is not yet fully determined for every combination of points by this equation. Besides being translated, a co-ordinate system may also be rotated. This signifies analytically: the relations of Euclidean geometry are covariant with respect to linear orthogonal transformations of the co-ordinates.

In applying Euclidean geometry to pre-relativistic mechanics a further indeterminateness enters through the choice of the co-ordinate system: the state of motion of the co-ordinate system is arbitrary to a certain degree, namely, in that substitutions of the co-ordinates of the form $x'=x-vt$

$$y'=y$$
$$z'=z$$

also appear possible. On the other hand, earlier mechanics did

not allow co-ordinate systems to be applied of which the states of motion were different from those expressed in these equations In this sense we speak of "inertial systems" In these favoured-inertial systems we are confronted with a new property of space so far as geometrical relations are concerned Regarded more accurately, this is not a property of space alone but of the four-dimensional continuum consisting of time and space conjointly

Appearance of Time.—At this point time enters explicitly into our discussion for the first time In their applications space (place) and time always occur together. Every event that happens in the world is determined by the space-co-ordinates x, y, z, and the time-co-ordinate t. Thus the physical description was four-dimensional right from the beginning But this four-dimensional continuum seemed to resolve itself into the three-dimensional continuum of space and the one-dimensional continuum of time. This apparent resolution owed its origin to the illusion that the meaning of the concept "simultaneity" is self-evident, and this illusion arises from the fact that we receive news of near events almost instantaneously owing to the agency of light

This faith in the absolute significance of simultaneity was destroyed by the law regulating the propagation of light in empty space or, respectively, by the Maxwell-Lorentz electro-dynamics. Two infinitely near points can be connected by means of a light-signal if the relation

$$ds^2 = c^2dt^2 - dx^2 - dy^2 - dz^2 = 0$$

holds for them It further follows that ds has a value which, for arbitrarily chosen infinitely near space-time points, is independent of the particular inertial system selected In agreement with this we find that for passing from one inertial system to another, linear equations of transformation hold which do not in general leave the time-values of the events unchanged It thus became manifest that the four-dimensional continuum of space cannot be split up into a time-continuum and a space-continuum except in an arbitrary way This invariant quantity ds may be measured by means of measuring-rods and clocks

Four-dimensional Geometry.—On the invariant ds a four-dimensional geometry may be built up which is in a large measure analogous to Euclidean geometry in three dimensions In this way physics becomes a sort of statics in a four-dimensional continuum Apart from the difference in the number of dimensions the latter continuum is distinguished from that of Euclidean geometry in that ds^2 may be greater or less than zero Corresponding to this we differentiate between time-like and space-like line-elements The boundary between them is marked out by the element of the "light-cone" $ds^2 = 0$ which starts out from every point If we consider only elements which belong to the same time-value, we have

$$-ds^2 = dx^2 + dy^2 + dz^2$$

These elements ds may have real counterparts in distances at rest and, as before, Euclidean geometry holds for these elements

Effect of Relativity, Special and General.—This is the modification which the doctrine of space and time has undergone through the restricted theory of relativity. The doctrine of space has been still further modified by the general theory of relativity, because this theory denies that the three-dimensional spatial section of the space-time continuum is Euclidean in character Therefore it asserts that Euclidean geometry does not hold for the relative positions of bodies that are continuously in contact

For the empirical law of the equality of inertial and gravitational mass led us to interpret the state of the continuum, in so far as it manifests itself with reference to a non-inertial system, as a gravitational field and to treat non-inertial systems as equivalent to inertial systems Referred to such a system, which is connected with the inertial system by a non-linear transformation of the co-ordinates, the metrical invariant ds^2 assumes the general form

$$ds^2 = \sum_{\mu\nu} g_{\mu\nu} dx_\mu dx_\nu,$$

where the $g_{\mu\nu}$'s are functions of the co-ordinates and where the sum is to be taken over the indices for all combinations 11, 12, . . . 44. The variability of the $g_{\mu\nu}$'s is equivalent to the existence of a gravitational field If the gravitational field is sufficiently general it is not possible at all to find an inertial system, that is, a co-ordinate system with reference to which ds^2 may be expressed in the simple form given above.

$$ds^2 = c^2dt^2 - dx^2 - dy^2 - dz^2,$$

but in this case, too, there is in the infinitesimal neighbourhood of a space-time point a local system of reference for which the last-mentioned simple form for ds holds This state of the facts leads to a type of geometry which Riemann's genius created more than half a century before the advent of the general theory of relativity of which Riemann divined the high importance for physics

Riemann's Geometry.—Riemann's geometry of an n-dimensional space bears the same relation to Euclidean geometry of an n-dimensional space as the general geometry of curved surfaces bears to the geometry of the plane For the infinitesimal neighbourhood of a point on a curved surface there is a local co-ordinate system in which the distance ds between two infinitely near points is given by the equation

$$ds^2 = dx^2 + dy^2.$$

For any arbitrary (Gaussian) co-ordinate-system, however, an expression of the form

$$ds^2 = g_{11}dx^2 + 2g_{12}dx_1dx_2 + g_{22}dx_2^2$$

holds in a finite region of the curved surface If the $g_{\mu\nu}$'s are given as functions of x_1 and x_2 the surface is then fully determined geometrically For from this formula we can calculate for every combination of two infinitely near points on the surface the length ds of the minute rod connecting them; and with the help of this formula all networks that can be constructed on the surface with these little rods can be calculated In particular, the "curvature" at every point of the surface can be calculated; this is the quantity that expresses to what extent and in what way the laws regulating the positions of the minute rods in the immediate vicinity of the point under consideration deviate from those of the geometry of the plane

This theory of surfaces by Gauss has been extended by Riemann to continua of any arbitrary number of dimensions and has thus paved the way for the general theory of relativity For it was shown above that corresponding to two infinitely near space-time points there is a number ds which can be obtained by measurement with rigid measuring-rods and clocks (in the case of time-like elements, indeed, with a clock alone) This quantity occurs in the mathematical theory in place of the length of the minute rods in three-dimensional geometry The curves for which $\int ds$ has stationary values determine the paths of material points and rays of light in the gravitational field, and the "curvature" of space is dependent on the matter distributed over space

Just as in Euclidean geometry the space-concept refers to the position-possibilities of rigid bodies, so in the general theory of relativity the space-time-concept refers to the behaviour of rigid bodies and clocks The space-time-continuum however differs from the space-continuum in that the laws regulating the behaviour of these objects (clocks and measuring-rods) depend on where they happen to be The continuum (or the quantities that describe it) enters explicitly into the laws of nature, and conversely these properties of the continuum are determined by physical factors The relations that connect space and time can no longer be kept distinct from physics proper Nothing certain is known of what the properties of the space-time-continuum may be as a whole Through the general theory of relativity, however, the view that the continuum is infinite in its time-like extent but finite in its space-like extent has gained in probability

TIME

The physical time-concept answers to the time-concept of the extra-scientific mind Now, the latter has its root in the time-order of the experiences of the individual, and this order we must

accept as something primarily given. One experiences the moment "now," or, expressed more accurately, the present sense-experience (*Sinnen-Erlebnis*) combined with the recollection of (earlier) sense-experiences. That is why the sense-experiences seem to form a series, namely the time-series indicated by "earlier" and "later." The experience-series is thought of as a one-dimensional continuum. Experience-series can repeat themselves and can then be recognized. They can also be repeated inexactly, wherein some events are replaced by others without the character of the repetition becoming lost for us. In this way we form the time-concept as a one-dimensional frame which can be filled in by experiences in various ways. The same series of experiences answer to the same subjective time-intervals.

The transition from this "subjective" time (*Ich-Zeit*) to the time-concept of pre-scientific thought is connected with the formation of the idea that there is a real external world independent of the subject. In this sense the (objective) event is made to correspond with the subjective experience. In the same sense there is attributed to the "subjective" time of the experience a "time" of the corresponding "objective" event. In contrast with experiences external events and their order in time claim validity for all subjects.

This process of objectification would encounter no difficulties were the time-order of the experiences corresponding to a series of external events the same for all individuals. In the case of the immediate visual perceptions of our daily lives, this correspondence is exact. That is why the idea that there is an objective time-order became established to an extraordinary extent. In working out the idea of an objective world of external events in greater detail, it was found necessary to make events and experiences depend on each other in a more complicated way. This was at first done by means of rules and modes of thought instinctively gained, in which the conception of space plays a particularly prominent part. This process of refinement leads ultimately to natural science.

The measurement of time is effected by means of clocks. A clock is a thing which automatically passes in succession through a (practically) equal series of events (period). The number of periods (clock-time) elapsed serves as a measure of time. The meaning of this definition is at once clear if the event occurs in the immediate vicinity of the clock in space; for all observers then observe the same clock-time simultaneously with the event (by means of the eye) independently of their position. Until the theory of relativity was propounded it was assumed that the conception of simultaneity had an absolute objective meaning also for events separated in space.

This assumption was demolished by the discovery of the law of propagation of light. For if the velocity of light in empty space is to be a quantity that is independent of the choice (or, respectively, of the state of motion) of the inertial system to which it is referred, no absolute meaning can be assigned to the conception of the simultaneity of events that occur at points separated by a distance in space. Rather, a special time must be allocated to every inertial system. If no co-ordinate system (inertial system) is used as a basis of reference there is no sense in asserting that events at different points in space occur simultaneously. It is in consequence of this that space and time are welded together into a uniform four-dimensional continuum. *See* RELATIVITY. (A. EI.)

Electro-magnetic Field.—We commonly say that a material object exists in *space* and in *time*. The scientist often adds that it is in a *gravitational field* and in an *electro-magnetic field*. By these four terms we seem to be attributing four different backgrounds to the object. But already three of these have been reduced to one; the special theory of relativity has amalgamated space and time into space-time; and the general theory of relativity with its Riemannian geometry has absorbed the gravitational field into space-time. Is it not possible to make a further generalization so as to absorb the electro-magnetic field? If so there will be but a single background to all material activity—one unified field.

Progress has been made towards this anticipated unification, but the theories are, as yet, not entirely definitive. The chief trouble is that electro-magnetism cannot be fully treated without entering into problems of electrons and the fine structure of matter; so that the field theory is held back pending developments in our understanding of atomic physics and quanta. The best known unified field theory is that of H. Weyl, proposed in 1918. He showed that a rather more general geometry than that of Riemann affords place for four coefficients additional to the ten $g_{\mu\nu}$, and that these can be identified with the four electro-magnetic potentials. A further development and reconstruction was given by A. S. Eddington in 1921. Starting from an "affine geometry" of the most general type, he found that a world-tensor can be derived which breaks up into a symmetrical and anti-symmetrical part. The symmetrical part provides a Riemannian metric, and therefore comprises space, time and gravitation; the antisymmetrical part furnishes the electro-magnetic field. Thus, whilst the gravitational and electro-magnetic fields are seen to arise from a single background, the bifurcation is recognized to be very deep-seated. Einstein proposed certain developments and modifications of this theory in 1923.

Early in 1929 Einstein announced that he had reached a new solution of this problem of unification; and there was much public curiosity as to his new theory. There is little that can be said of a non-technical character about it, since the differences from previous unified theories can only be realized by experts, and its attractiveness (or otherwise) depends on the relative simplicity of the mathematical formula which expresses the field-law. In fact, the whole point left unsettled was the particular form of the mathematical expression, so that an exposition of Einstein's latest theory, which leaves out the mathematics, leaves out its main point. It may be said, however, that Einstein's geometrical foundation is a Riemannian geometry coupled with a postulate of distant parallelism. If two ships are near together we can say whether they are or are not sailing on parallel courses; but if they are some thousands of miles apart there is no meaning or definition of what shall be called parallel courses. Similarly, in Riemannian geometry there is no distant parallelism. Einstein postulates that although, conformably to Riemannian geometry, we cannot define parallel lines at a great distance apart by reference to space measures alone, by taking also into account electrical measurements a unique definition can be given. By conspiring to provide this distant parallelism the electro-magnetic and gravitational quantities are brought into association. The theory has not yet been fully worked out, and judgment must be suspended as to whether it will satisfy all requirements. (A. S. E.)

SPADE-FISH (*Chaetodipterus faber*), a very deep-bodied, almost circular fish of the family *Ephippidae*, 2 to 3 ft. long, common in Atlantic waters from Massachusetts to Cuba and much prized for food. It has a small mouth, with brushlike teeth. The lateral line follows the humped curve of the body. In colour it is greyish, with four dark bands running from the top of the back down the body. It is also called angel-fish.

SPADE GUINEA, the name by which the guinea coined in the reign of George III. came to be known. It was so called because the reverse of the coin was designed with a shield pointed at the base after the fashion of a spade. *See* GUINEA.

SPADINI, ARMANDO (1883–1925), Italian painter, was born in Florence July 29, 1883. He first studied art in his native city but was chiefly inspired by the great Venetian artists, particularly by Giorgione and Paolo Veronese. Not until the International Exhibition at Venice in 1924 where 48 of his paintings were displayed was he assured of a definite place in modern Italian art. In 1910 he went to Rome where he established himself permanently. There he died on March 31, 1925. He painted a number of notable pastoral scenes and a few portraits but his best subjects are domestic scenes.

SPAGHETTI: *see* VERMICELLI and MACARONI.

SPAGNA, LO (d. after 1530), the usual designation (due to his Spanish origin) of the Italian painter Giovanni di Pietro, a pupil and assistant of Perugino. Nothing is known of his early

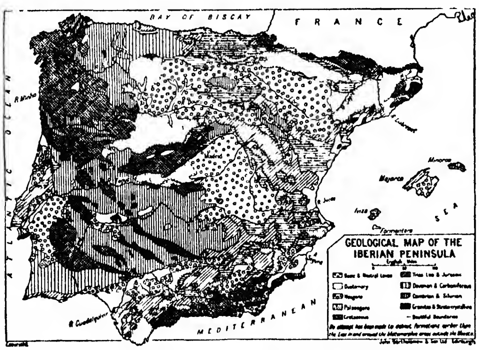
life There is a marked absence of individuality about his style, which seems like an imitation of the manner of Raphael and of Pinturicchio in a less virile form The chief of his numerous panel paintings are the "Nativity," in the Vatican, and the "Adoration of the Magi," at Berlin Lo Spagna's frescoes reach a higher standard of merit than his panel pictures The museum of the Capitol in Rome possesses a very beautiful series of life-sized fresco figures by him, representing Apollo and the Nine Muses from la Magliana, formerly ascribed to Raphael

SPAHIS, originally the holders of fiefs in Central Asia who yielded personal military service to their superior chief (in Persian *sipari*, meaning warriors, and synonymous with *sepoy*) In time the term came to be applied to the soldiery furnished in their own stead A similar institution existed in Turkey, and the "Spahis" were the light irregular cavalry which from the time of Sultan Amurath I (1326) down to the beginning of the 19th century formed the flower of the Turkish army, at one period they are estimated to have numbered 130,000. "Spahis" is the term now applied to certain native cavalry regiments in Algiers and Tunis, officered by Frenchmen

SPAHLINGER, HENRY (1882–), Swiss bacteriologist, was born at Geneva on Aug 8, 1882 He produced his first tuberculosis serum in 1912, and in 1913–14 treated a number of patients at London hospitals, with good results During the World War, being unable to continue the production of his serum, he manufactured large quantities of tetanus serum for the Allied armies In 1916 he began to reproduce his anti-tuberculous serum, which was in almost complete form in 1919 The Spahlinger treatment is based on two different therapeutic principles, according to the disease, passive immunization, or serum treatment, and active immunization, or vaccine treatment

SPAIN (*España*), a kingdom in the extreme south-west of Europe, comprising about eleven-thirteenths of the Iberian peninsula, in addition to the Balearic islands, the Canary islands, and Ceuta, on the Moroccan coast opposite to Gibraltar In 1920 the kingdom, apart from colonies, had a population of 21,338,381, and a total area of 194,800 sq miles It is thus rather more than twice the size of Great Britain The rock of Gibraltar, in the south, is considered to be one of the strongest fortresses in the world, and belongs to the British

Colonial Possessions.—The Spanish colonies are limited to the continent of Africa and islands off its coasts Spain exercises a



protectorate over part of north-west Morocco, excluding the Tangier zone, and, besides Ceuta, possesses Melilla, Ahucemas, Peñón de Vélez de la Gomera and the Chafarinas islands off the Moroccan coast. On the Atlantic coast she holds Ifni and the Cape Juby territory, which merges southwards into the Rio de Oro colony In the Gulf of Guinea Spain possesses the Fernando Po , Annobon, great and little Elobey, and Corisco islands, and, on the mainland, the Rio Muni district of Spanish Guinea, between the French Congo and the (French) mandated territory of the Cameroons in Africa

PHYSIOGRAPHY

The Iberian peninsula covers the major portion of that section of the earth's surface which is included between latitudes 43° 47′ N (Estaca de Vares) and 36° 0′ N (Isleta de Tarifa) and between the meridians of 3° 19′ E (Cabo de Creus) and 9° 30′ W (Cape Roca) Of its area of some 223,000 sq m , 85% is Spanish It has been thought proper, therefore, to treat here of the physical geography and geology of the peninsula as a whole rather than to confine the treatment to Spain

The peninsula is the least European in appearance of the three great Mediterranean peninsulas Its massif character, the great central Meseta, the narrow Strait of Gibraltar by which it is separated from Africa, and the high barrier of the Pyrenees by which it is separated from the rest of Europe, all give it the physical appearance of a disconnected outlier of the Moroccan Meseta rather than that of a part of Europe It is in very fact a world apart Not only is it separated from the rest of Europe by a range of mountains difficult to cross except at its extremities, it is also separated from the Mediterranean by coastal ranges which leave between themselves and the sea only narrow and discontinuous strips of coastal plain that alone, of all the peninsula, have a Mediterranean history

At first glance it would seem that the peninsula would serve to unite Africa and Europe, but, instead, its ranges of east-and-west mountains serve rather to separate them Moreover, the peninsula furnishes no natural traffic routes between the Mediterranean and the Atlantic or between the Mediterranean and northwestern Europe The closer physical connection with Africa than with the rest of Europe has had the disastrous consequence of the Islamic invasion and the five-hundred-year struggle with Islam which is accountable in large part for the slow development of Spain along European lines To the physical character of the peninsula is due likewise the separation of Portugal from Spain and the 700-year separation of the kingdoms of Castile and Aragon So sharply defined are the natural regions occupied by these two states that even now, though they have been united since the fifteenth century, their peoples differ sharply in physical type, customs, and social organization

The Coasts.—Seven-eighths of the border of the peninsula are washed by the sea, yet the peninsula as a whole has relatively little access to the sea and comparatively few good harbours Portugal alone of the whole peninsula has had an important maritime history and this has been due to the fact that the same Douro and Tagus rivers which by their deep canyons separate Portugal from the rest of the peninsula and explain her existence as a separate State afford good harbours in their estuaries

The high continental mass which forms the greater part of the kingdom of Spain has few navigable rivers and a coastline that is for the most part steep and rocky and with relatively few indentations that are easily approached from the interior The north coast has numerous indentations that form convenient harbours for small craft although the current that flows eastward along this coast frequently builds bars at their mouths The best harbours are to be found in the *rias* or fiord-like indentations of the coast of Galicia. Here are the fine natural harbours of Pontevedra, Vigo, Corunna, and Ferrol

The Portuguese seaboard is 500 m long and, as compared with the rest of the peninsula, relatively low On the southern half of the coast, however, mountain masses and spurs terminate in a number of high rocky headlands like Capes Mondego, Carvoeiro, da Roca, Espichel, de Sines, and St Vincent The lagoon of Aveiro and the estuaries of the Minho, Douro, Mondego, Tagus, Sado, and Guadiana rivers deeply indent the coast and furnish the principal harbours

Along the Gulf of Cadiz is the broadest coastal plain of the whole peninsula. Eastward as far as the marshes at the mouth of the Guadalquivir (Las Marismas) it is lined by a series of sand dunes and bordered in part by a line of low, wave-built islands Eastward from the mouth of the Guadalquivir the coast is more varied and includes the excellent harbour of the Bay of Cadiz

The Mediterranean coast is bold and rocky from the Strait of Gibraltar almost to Cape Palos but is broken by the British-

owned harbour of Gibraltar and the fine harbour of Cartagena. North of Cape Palos the coastal ranges again recede leaving a narrow coastal plain; but, in the northern part of the province of Alicante the mountains again advance to the sea and form the lofty headland of Cape de la Nao. The whole coast of the Bay of Valencia is low and swampy and lined with lagoons, furnishing little in the way of good harbours. All this coast is built of sediments brought down from the Meseta. This sedimentary character culminates in the great delta of the Ebro river. North of the mouth of the Ebro the coast alternates between *playas* and rocky headlands. The Llobregat river also forms a considerable delta just south of the harbour of Barcelona. From Barcelona a long monotonous sand-beach extends to the mouth of the Tordera river. Here begins the famous "costa brava" divided into two sections by the Gulf of Rosas and presenting a rough varied coast line of deep coves and steep, rocky bluffs.

The surface of the Iberian peninsula is noted for its striking contrasts and its vast expanses of dreary uniformity. There are mountains rising with Alpine grandeur above the snow line, but often sheltering rich and beautiful valleys at their base. Naked walls of white limestone tower above dark woods of cork and olive. In other parts, as in the Basque country, in Galicia, in the Serrania de Cuenca (between the headwaters of the Tagus and those of the Júcar), in the Sierra de Albarracin (between the headwaters of the Tagus and those of the Guadalquivir), there are extensive tracts of undulating forest-clad hill country. Almost contiguous to these there are broad plains of level tableland, some almost uninhabitable and some with a network of irrigation canals and richly cultivated like the Requena of Valencia. Continuous mountain ranges and broad tablelands give the prevailing character to the scenery; but there are, in addition, lofty isolated mountain peaks such as Monseny, Montserrat, and Mont Sant in Catalonia, the Peña Golosa in Valencia, and Moncayo on the border of Aragon and Old Castile, as well as many small secluded valleys such as those of Vich and Olot among the Catalonian Pyrenees.

The Meseta.—More than half the Iberian peninsula is occupied by the Meseta, an ancient earth-block consisting for the most part of flat-lying strata, broken and eroded and reduced in large part to a state of peneplanation. The Meseta slopes gradually from north to south and from west to east, its average altitude being about 2,000 ft. On the north it is bordered by the Cantabrian mountains and on the north-east by the Iberian ranges which separate the Meseta from the deep tectonic depression in which flows the Ebro river and terminate near the Gulf of Valencia. On the south the Meseta is bordered by the Sierra Morena, which is actually only the steep southern edge of the Meseta along the Baetic depression, and the Sierra de Alcaraz between the headwaters of the Guadalquivir and Segura rivers.

The Cantabrian mountains are divided into two sections—the Cantabro-Asturian section on the northern border of the Meseta and the Galician section which extends into Portugal as far as the Douro river. The Cantabro-Asturian section runs sensibly parallel to the north coast and culminates in the Peña de Cerredo (8,794 ft.), the highest point in the ranges of the Meseta. A characteristic of these mountains is the many *parameras* or isolated plateaux surrounded by steep mountains or walls of sheer cliffs. On account of the diversity of their origin and their many interruptions the Iberian ranges can better be characterized as the upturned north-east corner of the Meseta rather than a true mountain system. It reaches its highest point in the Sierra de Moncayo (7,593 ft.). South of the Jalón river it divides into two sections. One which borders on the Meseta forms the broken and picturesque Serrania de Cuenca. The other which lies nearer the Ebro depression forms the coast ranges that border the low, lagoon-strewn Bay of Valencia.

The Meseta is divided into northern and southern submesetas, representing respectively the ancient kingdoms of Castile and Aragon, by a central cordillera. This central cordillera consists of a series of crust-block mountains formed by successive fractures and vertical movements and extending *en echelon* north-eastward from the Atlantic coast near Lisbon to the Nudo de Albarracín where it connects with the Iberian ranges. It divides the basin of the Douro river from that of the Tagus. There are lofty peaks reaching above the line of perpetual snow in the sierras of this central cordillera. The highest peak, the Plaza del Almanzo (8,727 ft.) in the Sierra de Gredos, is only a little lower than the highest of the Cantabrian peaks, while the Pico de Peñalara in the Sierra de Guadarrama reaches 7,888 ft. Even these highest crests are, however, only about 5,000 ft. above the general level of the Meseta. Between the Sierra de Guadarrama and the Sierra de Gredos and between the latter and the Sierra de Gata are high irregular surfaces filled with hills and *parameras*. Parallel to the western part of the central cordillera between the basins of the Tagus and Guadiana rivers are the Montes de Toledo, a shorter series of sierras that form a denuded highland of relatively low elevation and are separated from the Iberian ranges by the section of the Meseta known as La Mancha. Their highest point is Las Villuercas (4,920 ft.) in the Sierra de Guadalupe. Their westward extension into Portugal is known as the Montañas de Alentejo. The Sierra Morena is an even less continuous range than the central cordillera or the Montes de Toledo. Its westerly extension into Portugal ends at the rocky headland of Cape St. Vincent.

Geologically, geographically, and politically the Meseta is the true Spain. On all sides it is in general remarkably isolated from the coast so that the passes on its border and the river valleys that lead from it to the coast and to the Ebro and Guadalquivir depressions have been from earliest times geographical features of the highest importance. On the north-west, communication between León and Galicia is furnished by the Sil river which at an early date was followed by military roads and now forms part of the route of the railway to the port of Corunna. In the Cantabrian mountains the passes are fairly numerous and over them lie the routes of several railways connecting the interior with the ports of the Bay of Biscay. The two most remarkable passes in these mountains are the Pass of Pájares which carries the railway from León to Oviedo and the port of Gijón and that of Reinosa which leads down to the deep valley of the Besaya and is crossed by the railway from Valladolid to Santander. The east part of the range is crossed by railways from Burgos to Bilboa and San Sebastian, the latter following the picturesque gorge of Pancorbo and crossing the range at Idiazobal.

On the north-east the valley of the Jalón river affords the most important communication between Madrid and the Ebro depression. At an early date an important military road followed this depression. It is now traversed by the railway from Madrid to Saragossa. Farther south the southerly extension of the Iberian ranges long made direct communication between Madrid and Valencia difficult, and even now, although a branch line connects the Jalón valley with the coastal railway a short distance north of Valencia, the main communications between Madrid and the east and south-east coasts are across the south-eastern part of the Meseta and the hill country between the Meseta and the Mediterranean.

The descent from the Meseta to the depression of the Guadalquivir is comparatively gradual but passes through the eastern part of the Sierra Morena are few, the principal one being the Puerto de Despeñaperros where the Magaña river, a tributary of the Guadalimar, has cut a deep gorge that the railway from Andalusia to Madrid follows in its ascent to the Meseta.

The central cordillera also offers considerable obstruction to easy communication between the northern and southern submesetas, although the hilly intervals between the sierras afford comparatively easy routes. Carriage roads cross the three main passes in the Sierra de Guadarrama (the passes of Somosierra, in the north-east, Novacerrada near the Pico de Peñalara, and Guadarrama a few miles south and west), while the railway from Madrid to Segovia passes through a tunnel close to the Guadarrama Pass and that from Madrid to Avila crosses the south-western portion of the same sierra by a remarkable series of tunnels and cuts. The Sierra de Gredo has a road across it connecting Avila with Talavera de la Reina by way of the Puerto de Pico; but for the most part there are only bridle-paths across

this sierra and the Sierra de Gata and no railway crosses either of them.

The Ebro and Baetic Depressions.—The Meseta is bordered on the north-east and on the south by two great transverse depressions. The most striking is that on the south, known as the Baetic depression now deeply eroded by the bed of the Guadalquivir It is a gigantic fracture that has cut like a knife across all the strata of the Meseta and stands out with remarkable clearness from Cape St Vincent to the eastern end of the Sierra Morena The present Baetic depression is believed to be the remains of a strait which, up to the Tertiary period, connected the Mediterranean with the Atlantic Later, on account of movements that produced the Penibaetic cordillera by which the present depression is bounded on the south and south-east, this strait was reduced to a gulf opening only to the Atlantic, and in time converted, whether by further uplift or by sedimentation alone, to the present valley. The sedimentary deposits of the Guadalquivir which flows along the most abrupt border of the depression at the foot of the Meseta has been built up on the materials worn off from the Meseta during the period of submergence and the sediments of marine origin to form the present fertile valley of Andalusia

The Ebro depression forms a deep ravine between the north-east corner of the Meseta and the Pyrenees Its two bordering walls converge to form an angle at the point where the depression is shut off from the Mediterranean by the Catalan coast range through which the Ebro river has now cut a tortuous gorge. At one time the depression was occupied by the sea which penetrated by way of the Gulf of Rosas but did not extend through to the Bay of Biscay. Later when the Catalan coast range emerged the depression was converted into a closed lake The definition of the Ebro river and the successive terraces which now characterize both sides of the depression were brought about by the later uplift to which is due the present architecture of the Pyrenees.

The Ebro valley is divided into two sections by spurs from the Pyrenees on the one side and from the Sierra del Moncayo of the Iberian ranges on the other The uppermost of these, a plateau of between 1,000 and 1,300 ft above sea-level, is only about one-fourth the size of the lower portion. The valley of the Guadalquivir is also divided into an upper and a lower section as indicated by the change in the course of the river from a due west to a more south-west direction. The small upper valley is of considerable elevation while the much larger lower valley is mainly lowland and from Seville to the sea is composed of a perfectly level and marshy alluvium (Las Marismas).

Mountains Outside the Meseta Border.—The Pyrenees (*q v*) form a continuous wall between Spain and France with an average altitude higher than that of the Alps Their snow-capped crests reach their highest point in the Pico de Aneto (10,965 ft) in the great central massif of granitic rocks that form the core of the range Few trails and no railroads cross the Pyrenees The Catalan coast range which separates the Ebro depression from the coast is the youngest range of the peninsula and all evidence indicates that the region has suffered movements that have taken place in the Quaternary period It represents the upper portions of a land mass now in large part submerged beneath the Mediterranean The peaks Monseny (5,713 ft.) and Montserrat (4,064 ft) are the outstanding crests Erosion has moulded them into beautifully picturesque forms Nearer the coast a series of hills of low elevation border the Catalan range throughout its whole length

The Baetic system of the south-east part of the peninsula has been described as due to a series of thrusts that had their focus farther south and forced up against the rigid mass of the Meseta the land mass located in front of it It is generally accepted that a long longitudinal fault which extends from the lower course of the Segura river to the Genil river divides the system into two groups. The mountains to the south of this fracture are known as the Penibaetic system They lie near the Mediterranean coast and are considered to be prolonged across the Strait of Gibraltar by the mountains of the Riff. The great block of the Sierra Nevada of the Penibaetic system contains the highest crests of the peninsula and reaches its greatest altitude in Cerro Mulhacén (11,417 ft). It is completely Alpine in character with glacial cirques, lakes, and moraines The Penibaetic system includes at its eastern end the volcanic zone that forms the Cape de Gata The extension westward from the Sierra Nevada to Point Marroquí appears to be cut by a series of transverse faults. The mountains north of the Penibaetic fault, though not exhibiting the high crests of the Penibaetic system, have a much broader area of high altitudes They close the eastern end of the Baetic depression and extend eastward to form the Cape de la Nao. The dividing line between them and the Iberian ranges is generally placed at the Júcar river

Rivers and Lakes.—The main water divide of the peninsula follows rather closely, in the north, east, and south, the border of the Meseta and the greater part of the drainage is westward by four large rivers, the Tagus (Spanish *Tajo*, Portuguese *Tejo*), Douro (Spanish *Duero*), Guadiana, and Guadalquivir Only a limited part of the north-east corner of the Meseta is drained by the Ebro on account of the barrier of the Iberian ranges, and all the remaining rivers which drain to the Mediterranean are short as compared with those draining to the Atlantic All the large rivers of the Atlantic slope rise in Spanish territory The Tagus and the Douro have their lower reaches in Portugal and the lower Guadiana is partly in Portugal and partly on the boundary Only the Guadalquivir and the Ebro, of the larger rivers, are entirely in Spanish territory The longest of the rivers is the Tagus (565 m) The rest in the order of their length are the Guadiana (510 m), the Douro (485 m), the Ebro (466 m), and the Guadalquivir The Minho, which divides the Cantabrian from the Galician mountains, and its tributary, the Sil, which rises in the north-west corner of the Meseta, is much shorter

The mouths of the Minho, Douro and Tagus form estuaries which provide good harbours for shipping but all rapidly become unnavigable toward the interior In fact only the Guadalquivir can really be classed as navigable for any appreciable distance from the sea, ships being able to ascend it as far as Seville The others flow in deep rocky valleys which they have cut across the Meseta Their water supply is scanty, their deeply cut valleys are difficult to cross, and the river beds so far below the level as to make them useless for irrigation The Ebro makes its way to the Mediterranean by way of a tortuous gorge and so affords no means of river transportation to the sea Its great importance lies in its plentiful waters for irrigation purposes derived from both the Pyrenees and the Cantabrian mountains Lakes of any considerable size are few, the only important ones being two coastal lagoons in the Mediterranean—the Albufera de Valencia, the Mar Menor in Murcia—and the Laguna de la Janda in Cadiz behind Cape Trafalgar There are many small alpine lakes, and small salt lakes are to be found in every steppe region

GEOLOGY

Geologically the Iberian peninsula consists of a great massif (the Meseta) which has been composed by Archaean, Palaeozoic, and eruptive rocks partly concealed by a covering of Tertiary strata but characterized by the absence, excepting in its margins, of any marine deposits of Mesozoic age, and bordered on the north, east and south by zones of folding in which the Mesozoic and early Tertiary beds are involved The Meseta is a fragment only of the great Hercynian mountain system which was formed across Europe at the close of the Carboniferous period. The earth-block which forms the Meseta was individualized at the close of the Palaeozoic era During the Mesozoic era the Hercynian system of which it is a part was shattered and large portions of it sank beneath the sea and were covered by Mesozoic and Tertiary strata But other portions remained above the sea and of these the Meseta was one. Around it the deposits of the Jurassic and Cretaceous seas were laid down During the Tertiary era these deposits together with the earlier Tertiary beds were crushed against the old massif, thus forming the folded zones of the Baetic ranges on the south, the hills of southern Aragon in the east, and the Pyrenees on the north

There are clear evidences of earlier (Huronian and Caledonian) movements on the Meseta, but worn folds of Carboniferous formations embedded in the Hercynian structure may represent in places an older discordant structure dependent on earlier movements.

Tertiary movements soldered to the Meseta the formations by the north-east, where the folding action lay within the early (Palaeogene) Tertiary period, and of the south-east, where the folding was most intense, in the later Neogene period before the Tortonian epoch. The Tertiary pressures also caused many important movements in the Hercynian massif itself. Ancient fractures were rejuvenated, large interior basins were formed, and the strata were folded and crushed with great violence in the borders of the massif. During the Pliocene period the Meseta was given a general tilt westward. Later differential Tertiary movements modified the Central Cordillera system and accentuated the separation of the northern from the southern submeseta, leaving them at very different altitudes from each other and from the marginal depressions and lowlands.

The areas of regional metamorphism on the Meseta are formed of plutonic rocks, broadly granites, which pass upwards into an Archaean, or strata crystalline series in Galicia, Portugal, and the Central Cordillera system. They appear elsewhere aligned with the Palaeozoic series, principally along a line from Alcántara to Andujar. This series shows these levels—the lowest, Augen-gneiss; the intermediate, micaceous gneiss with schists and crystalline limestones intercalated; and the uppermost, lustrous schists and phyllites. These materials appear now at the surface among granitic rocks—the massif of Galicia and North Portugal,—the central sierras,—in the Montes de Toledo, and in South Portugal on the plateau of Evora and Beja which extends eastward by the Sierra de Aracena to the Sierra Morena point north of Seville.

Palaeozoic.—The oldest Palaeozoic strata are referred, from their included fossils to the Cambrian, Ordovician and Silurian systems. They range through a vast region of Andalusia, Estremadura, Castile, Salamanca, León and Asturias, and along the peaks of the Pyrenees and the Cantabrian mountains. In eastern Galicia and Asturias, and in western León, the Cambrian and Silurian trendlines swing round a quarter-circle following the outline of Galicia and northern Portugal. The Silurian of the sierras (Ocejón, Alto Rey) lying to the north-east of the Sierra de Guadarrama trends south–south-west, south, and, finally, south-west. Round the gneissic vestiges of the Toledan massif the Cambrian and Silurian, partly metamorphosed, in the neighbourhood of the granites, trend west-ward and the north–west-ward in the Montes de Toledo and the Sierra de Altamira. From the Sierra Morena front the trendlines, running at first parallel to the line of front, swing to the west and west–north-west round the strata-crystalline of southern Portugal. Farther east they run freely to the north-west in the great belt of Palaeozoic which stretches from La Mancha to beyond the Portuguese frontier. The older Palaeozoic of the north culminates in the Teleno (7,181 ft.) belonging to the Montaños de León. In the south the Sierra Morena is the scarped southern edge of the main mass of the Palaeozoic, cut by a series of faults partly of Permian and partly of Pliocene date. The Palaeozoic also formed the two plateaux to the south of the Sierra Môrena and a low plateau in the east notable for the complex lead-silver zone of Linares and La Carolina; and a broad plateau in the west extending from the Andévalo district south of the Sierra de Cuacena to the western shores of Portugal.

In the hinterland the Palaeozoic Sierras trend finally to the north-west, washing the Hercynian axial lines which curve into this direction from both the Sierra de Toledo and the Sierra Morena. At Montoro the course of the Guadalquivir has been imposed on the Palaeozoic by the removal of overlying Tertiary formations. East of Almadén the Palaeozoic is pierced by Quaternary basalts of the Campo de Calatrova beyond which tongues of Mesozoic projecting from La Mancha bring the Guadiana drainage into the Palaeozoic area.

Mesozoic.—In Portugal the Mesozoic series consist of deposits laid down in the geosyncline which existed to the west of the Meseta during that era and which disappeared at its close after retreating north of the present Tagus river draining the Upper Cretaceous. Geosynclinal conditions were most marked during the Jurassic whose "Tusitanian" stage has a thickness of 5,000 ft. in the Torres Vedras area. Jurassic limestones sketch the structural skeleton of the Mesozoic fringe of the Meseta. In the Mondego region, a Jurassic upfold, flanked on two sides by Turmian formations, runs west–south-west to Soure and then west–north-west to Cape Mondego by Verrede and Buarcos. This axis delimits on the south an area of worn Cretaceous reliefs above which stand out the Jurassic of Contanhede separated from the sea by a broad belt of high dunes. The Cretaceous, which appears in depressions along the principal axis as well as on the flanks of the Jurassic zone, is widely developed in the Cintra region where the Jurassic scarcely emerges. South of the Tagus river movements of Alpine date have brought up the Jurassic to form the higher parts of the complicated Sierra Arrabida which runs west–south-west to Cape Espichel. In Algarve the Lias and Jurassic, with a fringe of Cretaceous towards the littoral, are folded against the southern edge of the plateau and contribute granite and limestones to the complexity of the zone.

The lower Carboniferous rocks of Spain consist partly of limestones and partly of sandstones and conglomerates like the culm of Devonshire. It is in the culm of the province of Huelva that the celebrated copper mines of Rio Tinto are worked. The Upper Carboniferous is formed, to a large extent, of sandstones and shales, with seams of coal; but beds of massive limestones are often intercalated, and some of these contain *Fusulina* and other fossils like those of the Russian Fusulina limestone. In the Cambrian and Silurian areas of the north-west, Tertiary movements have probably compressed the strata in the arc of the western Asturias, but not in the Carboniferous area to the east where the Carboniferous has its most extensive development in Spain, covering a considerable section of the eastern Asturias, and extending more or less continuously through the provinces of León, Valencia and Santander.

The blue-grey mountain limestone of the lower Carboniferous form the triple massif of the Picos de Europa and the crests of many sierras. The culm, which also forms mountains, especially along the upper Deva, marks the transition to the continental conditions in which originated the sandstones and slates of the middle Carboniferous, with their intercalated beds of coal, principally the beds of the Tangres and Mieres basins. Tertiary movements raised the Carboniferous along an east–west axis to form the Cantabrian chain.

To the north of the Carboniferous of the central Asturias lies an area of Mesozoic marine invasion with deposits in a belt trending east and west behind the Palaeozoic "island" by the Cabo de Peñas district. From Peña Prieta eastward the altitude of the summits of the Cantabrian chain declines and the Cretaceous is rapidly substituted for the Carboniferous. In the half-circle between Peña Tabra and the Sierra de Alcaraz the Meseta is bordered by highlands principally of Mesozoic formations. The tectonic relations between these highlands and the Cantabrian system, which continues eastward in the Cretaceous to the Pyrenean front, is not clear.

The Permian is probably represented by some of the red sandstones, conglomerates, and slates in the Pyrenees, in the Sierra de Cuenca and in Andalusia. The Triassic system is well-developed in the north of the peninsula along the Cantabrian chain and eastwards to the Mediterranean. It is composed of red and variegated sandstones, dolomites, and marl, and contains deposits of gypsum, aragonite, and rock salt. The Jurassic overlies these strata and is especially important in the eastern part of the peninsula between Castile and Aragon, along the Mediterranean border, in Andalusia, and on the flanks of the Pyrenees. The early Jurassic conglomerates and grits are followed by limestones, some dolomitic variegated marl, and overlying spongy limestones or dolomites. The neritic Lias and Jurassic are important only on the borders of New Castile.

The Cretaceous forms the broad plateau of the Lora on the southern front of the Cantabrian mountains north-west of Burgos

SPANISH SCENES

1. A wall and two of the many towers of the Alhambra, magnificent palace of ancient Moorish kings. Built within a strong fortress on a high plateau in Granada
2. View of Granada. The Mountain of the Sun in the Sierra Nevada seen in the background
3. Looking from a cathedral tower over the city of Cadiz towards the harbour
4. Narrow street in Cadiz. This type of street is often found in olden cities of Spain as well as in other countries of Europe
5. Looking across the bay toward Gibraltar from the city of Algeciras. The big rock may be seen in the distance

and extends southward and westward into a Cretaceous isthmus in the northern side of Miocene "Straits of Burgos." An upfold brings it to the surface again in the island-like Sierra de Atapuerca on the south side of the "straits" toward the Montes de Oca From the scarp of the Urbión the Cretaceous dips gently southward and Upper Cretaceous limestones form small, bare, fault-bounded plateaux sharply contrasting with the pine-clad slopes of the lower Cretaceous and appearing at the surface not only on the margin of the zone but in the upfolds of small radius among the Tertiaries of the Domo, at Burgo de Osma, Sovia and elsewhere.

South of the Jalom river beyond the Paramess de Molina the border of the Meseta is formed principally of Jurassic limestones and marl commonly capped by horizontal limestones of the Cretaceous and forming a series of high plains rather than mountains in which the *muela*, or molar-tooth, summit is typical. The different alineations, however, are known as the Serrania de Cuenca, Montes Universales, and Sierra de Albarracin.

Tertiary.—Deposits of Tertiary age cover rather more than a third of Spain On the Meseta the Tertiary formations were laid down in the basins of Old and New Castile and in the minor systems of Castello Branco (Beira Baixa), Badajoz, and others of the Tagus and Guadiana valleys. In the west arkose grits of Lutetian date from a broad, monotonous plain in the provinces of Zamora and Salamanca and the old Tertiary (Palaeogene) beds appear also in the east near Lerma and in the plateau of Sovia. Elsewhere the outer deposits of Palaeogene are insignificant The continental Miocene, unconformable on the Palaeogene, consists of fine-grained materials laid down within the basins of the Palaeogene, and the Cretaceous to which it is unconformable had been folded in the margins of the basins, by rivers (Tartonian), brackish ponds (Sarmatian) and in marshy ponds (Pontian) In spite of stratigraphic discontinuity the forms of the Miocene relief are constant and characteristic. The type form is the table-land (*mesa*), with its flat upper surface of the limestone cap (*paramo*), its slope of marl (*cuesta*), and its sands or clays of the lower slopes forming plains (*elanuras, canapiñas, campos*) As the erosion advances the worn table-lands appear as truncated pyramids or form low *mesas* capped by the beds of harder marl. Finally great stretches of plain are formed on the level of the Tortonian on lower Sarmatian Space will not permit a full description of the Tertiary formations elsewhere The Eocene marine strata are developed in the basin of the Ebro and Miocene deposits occupy some small tracts especially on the coast of Valencia although most of the sandy Tertiary rocks of the latter district are Pliocene In the Baetic depression the marl of the Tertiary rocks of whatever level are of great importance, supplying the rich soil of the Cijarafe olive groves west of Seville and of the vineyards of Jerez.

Quaternary deposits spread over about a tenth of the country. The largest tract of them is to be seen to the south of the Cantabrian mountains, although another but little smaller flanks the Sierra de Guadarrama and spreads out over the great plain from Madrid to Cáceres.

From the rivers Douro, Tagus, Guadalquivir and Ebro, E. H Pacheco has described recently four fundamental terraces at heights of 30, 100, 200 and 330 ft, which are fairly constant within limits of 4–33 ft from the higher terraces, and he has commented on the absence of terraces on the Spanish section of the Guadiana river. The highest terrace is of late Pliocene date and to it are referred the famous rañas, extensive platforms of coarse detritus high on the northern front of the Montes de Toledo. The others seem to be related to the terminal moraines of the Pleistocene glaciation with which, in some cases at least, they are continuous. There moraines are found as low at 2,300 ft. on the Sierra de Estrella (one of the westernmost sierras of the central cordillera); and the topography of the Picos de Europa (of the Cantabrian mountains), the Sierra de Guadarrama and the Sierra de Gredos (of the central cordilleras), the Sierra Nevada, and the Iberian ranges from the Demanda to Moncaya has been modified to some degree by glaciation. But the centres of glaciation in each of these cases were relatively small, and the action local. Only in the Pyrenees are the glacial phenomena of real topographical importance The terraces, on the other hand, are of first importance, making irrigation possible in areas otherwise arid. (X.)

CLIMATE AND SOILS

Looking at Spain as a whole, for the year as a whole, we can distinguish, in respect of temperature, the very different climates of the equable Biscayan and north Atlantic coasts; of the interior, with extremes of temperature always, but with a winter which varies from the traditional nine months of the higher parts of Old Castile to the short two-months winter of the lowlands of Extremadura; of the Mediterranean coast with its very short winter and rather hot summer, and of the subtropical south and south-east, where winter, in the popular sense, hardly exists.

More important is the distinction in respect of rainfall between Spain of the north-west and north (roughly as far south as the line León-Pamplona-Huesca), with a mean annual rainfall of 24 in and over, fairly well distributed over the year, and the rest of the country, arid Spain, with rains insufficient in quantity, or badly distributed, or, more commonly, both There is a general decline in the mean annual rainfall from north-west (Santiago, 66 in) to south-east (Almeria, *c.* 10 in), but this is interrupted by the minimal rainfall of the basin of Old Castile, where Salamanca and Zamora, like Zaragoza in the Ebro basin, lie within an isohyet of 12 in, and by the orographic rainfalls, which are sometimes remarkable; thus, in the Baetic calcareous zone, in spite of a rainless summer season, the annual rainfall may be of 80 in. on the outskirts of the Serranía de Ronda.

The rains of arid Spain are spasmodic, Mediterranean rains falling in large drops for a few hours of a few days of the year. They are also irregular in amount from year to year; the rainfall records of 95 years for San Fernando, near Cadiz, for example, show a mean deviation, from the mean, of 26%. Long-term data are accordingly necessary for the construction of satisfactory maps of rainfall, while the number of long-term stations is limited (contrast France, 31·3 in; Portugal, 31 6 in).

Irregularity of the seasonal rain-supply, and the entrenched courses of the rivers of the interior, prevent much use being made of their waters for the partial relief, by irrigation, of the prevailing aridity Both of these difficulties are now being overcome for the rivers of the Ebro system by the provision of immense engineering works. (*See* ARAGON.) On the lower courses of the rivers of the short eastern slope the relief is, by exception, highly favourable to the establishment of important irrigation systems. (*See* VALENCIA)

Properly conserved, arid soils, although they are inevitably exposed to the sterility resulting from sequences of years of drought, have, nevertheless, certain advantages of chemical composition, due to the smaller degree to which plant foods are lost by leaching, which enable them to maintain a standard of productivity lower than that of more humid regions and requiring a greater output of labour, but more independent of artificial fertilization, especially if natural manure is supplied by pasturing. Dry-farming, the *cultivo de secano*, is the third and most widespread of the geographical institutions of arid Spain

Subsoils include the Andalusian "black-earths" and new soils, chestnut or red in colour. An extreme type is the *calvero* soils, for which the Castilian name seems likely to become internationalized. In the *calveros*, which arise commonly from past or present attempts to extend cultivation beyond its proper limits, the soil cap is discontinuous and the native rock conspicuous on the surface; tufts of permanent vegetation depend on, and protect, the small patches of soil; in the open spaces lichens are the chief covering, with occasionally transitory grasses.

Saline soils occur locally, in the more arid parts of Old and, especially, of New Castile and of the Ebro basin, and elsewhere, but the extension of the saline area is greatly modified by human agency. In east Spain, in general, and in Andalusia, red soils, the "Mediterranean red earths," are commoner than chestnut, and in the dry south-eastern corner tawny or grey soils are commoner than red; the precise significance of the colour is not known.

FLORA

The Northern, humid area is dominated by mesophytic formations of the Central European and North Atlantic type, while the rest of Spain is characterized by xerophytic formations distinctly Mediterranean in type. Increasing aridity and proximity to the African continent are reflected in marked African features in the vegetation of the south-east. Further, owing to its extraordinary variety of climates, altitudes, exposures and soils, Spain is richer in botanic species than any other European district of the same size, and endemic species are particularly numerous. These are not only characteristic of the higher parts of the Pyrenees and of the Cantabrian and Central ranges, but they also occur in great numbers in the central plateaux of the interior. Of the 5,660 vascular species which have been identified, about one-third are Central European or Alpine in character, one-quarter are endemic, one-fifth are Mediterranean and one-twelfth are African and Atlantic.

At the present day less than 5% of Spain is under forest. Of this over one-third is pinewood. Deciduous forests are practically confined to the humid north, where Central European formations of oak, beech, chestnut, birch, ash and lime, with meadows and heath-moors, are dominant. In arid Spain the vegetation, eminently xerophytic, is mainly evergreen. Conifers, such as the Spanish pine (*Pinus halepensis*), the pinaster (*P. pinaster*), the Corsican pine (*P. larico*), the stone-pine (*P. pinea*) and the Pinsapo fir (*Abies pinsapo*) and junipers, typically *Juniperus thurifera,* are common, especially on the upper slopes of the main ranges, but by far the most typical trees of dry Spain are the two species of oak, *Quercus ilex,* the evergreen or holm-oak, and *Quercus suber,* the cork oak. *Quercus ilex* is the most widespread tree in Spain. Deciduous species are not entirely absent from arid Spain, but they are, however, very largely confined to the vegas, with their black poplar groves, and the higher, more humid valleys of the northern ranges bordering and crossing the central Mesetas. Here beech, birch and lime occur, but even many of these show drought-resisting features. Sweet chestnut woods are characteristic of siliceous mountain soils in the south. In central Spain, woodland formations are practically confined to the mountain slopes, and the predominating vegetation over the Mesetas is a scrub of evergreen bushes and large herbaceous plants of the Cistaceae and Labiatae families. Areas dominated by Cistus scrub are known to the Spaniards as *jarales,* and are particularly extensive over the Middle Tagus and Guadiana basins and on the slopes of the Sierra Morena, where the ladanum bush (*Cistus ladaniferus*) is particularly abundant. Areas, on the other hand, which are characterized by the aromatic Labiatae, such plants as thyme, lavender, sage and rosemary, are known as *tomillares* (from *tomillo,* thyme) and occur chiefly in the La Mancha (*q.v.*) region.

Leguminosae, particularly Spanish broom (*Spartium junceum*) and furze are also common in the interior.

In the past a far greater proportion of Spain was forested than is so at the present day. The pinewoods of the Iberic and Carpetanian ranges, the important cork oak-woods of the south and of Catalonia, and the many scattered stretches of evergreen oak are clearly relics of far greater forests, which have been destroyed by ruthless clearing and exploitation by man. As a result, in many of the uncultivated stretches of arid Spain there now exist formations which can only be regarded as degenerate forms of vegetation, due to the destruction of the original forests. Large areas in Murcia, in parts of La Mancha and on the plateaux of Guadix and Huescar in Granada, are covered with esparto grass (*q.v.*).

In the south-east of the peninsula the extreme aridity of much of the area, combined with the high temperatures, has given rise to semi-desert conditions, with a distinctly African type of vegetation. The dwarf palm (*Chamerops Humilis*) grows in this region, but is nowhere a very important feature of the vegetation.

The eastern districts, from Catalonia southward to Cape Nao, have a distinctly Mediterranean type of vegetation, evergreen shrubs, including many aromatics, of the class known to the French as maquis and described by the Spaniards as *monte bajo* to distinguish it from *monte alto*—the forest.

FAUNA

Cut off from Europe by the Pyrenees and in recent geological touch with Africa, Spain has European fauna of special types, with marked African affinities in the South and many local varieties.

Of mammals which come under this head the most important are the common genet (*Genetta genetta*), which extends into south-west France, and a species of ichneumon (*Herpestes widdringtonii*), which is restricted to the peninsula. Both the above constitute the only European representatives of the tropical Old World family of Viverridae or civets. The Barbary ape (*Macacus sylvanus*), which inhabits the peninsula of Gibraltar and is the only species existing in a wild state in Europe, is generally believed to have been introduced from Africa at a very early date. Of the mammals peculiar to the peninsula, but showing greater affinities with the fauna of Northern and Central Europe, the most typical are the Spanish lynx (*Lynx pardellus*), a purely Iberian species; the Andalusian wild cat (*Felis sylvestris tartessia*); the Spanish wolf (*Canis lupus signatus*), peculiar to central Spain; the Spanish fox (*Vulpes vulpes silaceus*); the Iberian weasel (*Mustela iberica*), the Spanish red deer (*Cervus elaphus*), the Iberian hare (*Lepus granatensis*), the large Guadarrama squirrel (*Sciurus vulgaris infuscatus*), several voles and various smaller forms, such as the Andalusian dormouse.

The birds of Spain are very numerous, partly owing to the position of the peninsula on the route of bird migration between North Europe and Africa, by way of the Strait of Gibraltar. Spain is visited by groups migrating south in winter and others moving north in spring. Thus the guillemot and gannet appear on the Cantabrian coast in winter, while the flamingo nests in the Quadalquivir marshes in May.

A feature of Spanish ornithology is the large number and variety of the birds of prey. These include the bearded vulture (*Gypaëtus barbatus grandis*), still common in the mountains of central and northern Spain, though dying out elsewhere, and two special forms, the Spanish eagle-owl (*Bubo bubo hispanus*), confined to the peninsula, and the Spanish Imperial eagle (*Aquila heliaca adalberti*), which is also found in North Africa. Other peculiar subspecies are the royal cuckoo (*Cuculus canorus minor*), and the Iberian green woodpecker (*Picus viridis sharpei*). The azure-winged magpie (*Cyanopica cyanus cooki*) is remarkable in that it represents a genus which only occurs elsewhere in Eastern Asia. The red-legged partridge (*Alectoris rufa*) and two species of sand-grouse (*Pterocles orientalis* and *P. alchata*), though not peculiar to the peninsula, are common in the so-called steppe areas and, besides the flamingo (*Phoenicopterus ruber*), the southern shrike (*Lanius excubitor*), two quails, the Andalusian hemipode (*Turnix sylvatica*), and other water birds, are characteristic of the south.

Though a large number of reptiles occur in Spain, only the viper (*Pelias berus*), which is not abundant, is deadly to man. The great *Coelopeltis monspessulanus,* sometimes 5 ft. long, is the largest Spanish lizard, while *Lacerta ocellata* is a large species abundant in central and southern Spain. The common Iberian land-tortoise (*Testudo iberica*) and the European pond-tortoise (*Emys orbicularis*) are also typical. The chameleon (*Chamoeleon vulgaris*), a rare African form, is sometimes found in southern Spain. The amphibians exhibit many autochthonous forms, notably *Chioglossa lusitanica,* a species of salamander, while the repulsive "gallipato" (*Pleurodeles waltli*), is abundant in tanks and pools. Insect life is remarkably rich, and many of the numerous species of beetles and butterflies are endemic. Trout abound in the mountain streams and lakes, and barbel, carp and tench are other common fresh-water fish.

POPULATION

The Iberian peninsula has such important remains of most of the phases of civilization, from the later Palaeolithic age onwards, that the racial make-up of its population is, doubtless, highly complex. It is said that, as in the Dordogne in France, and on the Welsh moorlands and elsewhere, very long-headed dark types which were characteristic of Western Europe in the Aurignacian period of the Palaeolithic, still occur among the people of the Basque Provinces and Tras-os-Montes. The peninsula, generally,

Provinces	Area in sq miles	Pop. in 1900	Pop in 1925 (estimate)	Density per sq m. in 1925

is inhabited by long-headed peoples without any of the large blocks of broad-heads which characterize, for example, France and Italy.

The Basque language (*q.v.*) is a mysterious survival in the western Pyrenees (Navarre), and in regions to the west of these, which are thence called the Basque Provinces. The Catalan language, widely spoken in north-east Spain and French Roussillon, is allied to Balearic speech and Provençal, and differs in many ways from Castilian Spanish, though both are derived, in the main, from Latin. The Galician dialect is akin to Portuguese. It was usually the east, south, and west coasts of the peninsula that were mostly in contact with ancient Mediterranean civilizations, and the contrast in culture, and in political relations between Galicia and the Asturias, on the one hand, and the rest of Spain has been marked in different ways at many different periods, but the natural differences between "pluviose" and "arid" Spain have played their parts here. The great regions of Spain, italicized in the table in the preceding column, all have bases in physical features.

It has often been said that Roman Spain had a large population, and estimates up to 40 or 50 millions have been ventured, but little is known save that Tarraco (Tarragona) was a very large place and that there were large garrisons. The first Spanish census was taken in 1594 and, if an estimate be added for parts not then included, a figure of 8,200,000 is reached. In 1787 the total was 10,268,150, in 1857 it was 15,464,340, in 1897 it had risen only to 18,132,475. Starting, therefore, with a relatively high figure in the 16th century, Spain fell behind other lands in the 19th century, when these developed industry. The Spanish empire in the New World was a severe drain upon the manhood.

It will be noted that there has been an increase in population in all the provinces since 1900.

The towns with a population (estimated) over 100,000 in Dec 1925 were —

Town	Pop. 1925	Town	Pop. 1925
Madrid	791,511	Saragossa	150,051
Barcelona	745,711	Murcia	149,485
Valencia	262,647	Bilbao	144,985
Seville	212,3[illegible]6	Granada	106,461
Málaga	157,250		

Madrid and Barcelona show the greatest increase in population. In 1877 Madrid had only 397,816 inhabitants; this had risen to 539,835 in 1900, and the subsequent quarter of a century has brought it to 791,511. Barcelona had 277,000 inhabitants in 1877; they had increased to 533,000 in 1900, and reached 745,711 in 1925.

Religion.—Roman Catholicism is the established religion, and, with the exception of a small number of Protestants, Jews, etc., claims the adherence of the whole population. The relations between Church and State were defined by concordat in 1851, and this has remained in force, except for the admission of more religious orders than those mentioned in the document, until the present time. The Constitution requires the State to support the clergy, the church buildings, etc. There are nine metropolitan sees and 51 suffragan sees. The archbishop of Toledo is primate, and the other archbishops reign at Burgos, Granada, Compostella, Saragossa, Seville, Tarragona, Valencia and Valladolid. Difficulties arose for the Roman Church during the Revolution from 1868 to 1877, especially in Catalonia and Andalusia, which were centres of Republicanism. But, with the Restoration and the great favour shown to the Church by the new monarchs, there came a marked revival in ecclesiastical and monastic life. The religious orders are very influential in education. There were 4,497 religious houses in 1924, 948 for men and 3,549 for women. Of those for the men, eight were technical schools, 215 were given over to preparation for the priesthood, 103 to charity and 90 to the simple meditative monastic life, while 532 were devoted to education. Charity, education (1,309 establishments) and meditation are the chief functions of the orders for women. The total number of monks would be (1924) about 12,000, and nuns 42,000. Spain possesses 66 cathedrals, 22 collegiate churches, 20,440 parishes and 15,107 chapels. Liberty of worship is allowed.

Constitution and Government.—Spain is an hereditary monarchy, the Constitution of which was voted by the Cortes and became law in 1876. The sovereign is inviolable, but his ministers are responsible to the Cortes, and none of his decrees is valid unless countersigned by a minister. The legislative authority is exercised by the sovereign in conjunction with the Cortes, a body composed of two houses—a senate and a chamber of deputies. The Senate is composed of members of three classes: (1) Members by right of birth or office—princes; nobles (with a certain annual income) and holding the rank of grandee (*grande*), captains-general of the army; admirals of the navy, the patri-

arch of the Indies; archbishops; cardinals; the presidents of the Council of State and of the Supreme Court and other high officials, all of whom must have retained their appointments for two years; (2) members nominated by the sovereign for life; and (3) members elected by the provinces, academies, universities, dioceses and State corporations. The members belonging to the first two classes must not exceed 180 in number, and there may be the same number of members of the third class. The lower house of the Cortes has 417 deputies, who cannot take State office pensions or salaries; but the ministers and State officials of a salary higher than 15,000 pesetas are exempted from this law. Both Congress (Chamber of Deputies) and Senate are supposed to meet every year. The executive is vested under the monarch in a council of ministers. The ministerial departments are Foreign Affairs, Justice and Worship, War, Marine, Finance, Interior, Public Instruction, Public Works and Labour.

In 1923 a decree appointed Gen. Primo de Rivera chief of the Government and president of a military directory. This was superseded by a civil Government in 1925 under Gen. de Rivera, composed of members of the new political party *Union Patriotica.* All the former ministerial departments have been set up again, but really everything continues much as before. Martial law was proclaimed from Sept. 1926 to Jan. 1927, and thereafter a general assembly was called.

Local Government.—Since 1918 every commune has its own *Ayuntamiento,* consisting of from five to 50 *Regidores* or *Concejales.* The *Ayuntamientos* have charge of the entire local government. Half the members are elected every second year, and the body appoints its own executive. Each Spanish province has its *Diputacion Provincial,* elected by the constituencies. This assembly meets annually and is permanently represented by the *Comision Provincial,* appointed annually. The State executive and the Cortes have little power to interfere with local government. The Basque Provinces have lost a former large measure of self-government, but though they are governed like the rest of Spain, certain *fueros,* or exemptions, are given them, a new statute of exemptions coming into force in 1925. All mayors and municipal councils in Spain were dismissed by decree in 1923 and replaced by members of the Associated Council of Householders. In 1924 a royal decree made possible a law establishing the *Estatuto Municipal,* governing the future municipal organization and administration. More freedom is granted to the *Ayuntamiento,* especially in drawing up its own organization. Women have been given the suffrage, and the voting age for males and females has been reduced to 23 years, and special representation was given to guilds and other corporations.

Spanish law is founded on Roman law, Gothic common law, and the national code proclaimed at the meeting of the Cortes at Toro in 1501 (the *Leyes de Toro*). The present civil code was put into force on May 1, 1889, for the whole kingdom. The penal code dates from 1870 and was modified in 1877. The commercial code was put into force on Aug. 22, 1885, the code of civil procedure on April 1, 1881, and the code of criminal procedure on June 22, 1882. In addition to courts held by justices of the peace, there are 522 courts of first instance (in the *Partidos judiciales*), above these come 50 provincial high courts, with appeal to the 15 divisional high courts, while there is a supreme high court at Madrid. Justices of the peace deal only with petty offences and small civil cases. A court of minors has been established.

DEFENCE

Historical.—The feudal sovereignties of mediaeval Spain differed but little, in their military organization, from other feudal states (*see* Army). Mercenaries were the only forces on which reliance was placed for foreign wars. These troops called *almugávares* (Arabic=scouts) won a great reputation on Italian and Greek battlefields of the 13th century, and with many transformations in name and character appeared from time to time up to the Peninsular War. Castile, however, had a military system very different from the rest. The forces of the kingdom were composed of local contingents similar to the English *fyrd,* professional soldiers who were paid followers of the great lords, and the heavy cavalry of the military orders. The groups of cities called *Hermandades,* while they existed, also had permanent forces in their pay. At the union of Castile and Aragon the Castilian methods received a more general application. The new *Hermandad* was partly a light cavalry, partly a police, and was organized in the

ratio of one soldier to every hundred families In the conquest of Grenada (1482–92) *mesnadas* or contingents were furnished by the crown, the nobles and the cities, and permanently kept in the field. The *Hermandad* served throughout the war as a matter of course. From the veterans of this war was drawn the army which in the Italian wars won its reputation as the first army in Europe.

With the Italian wars of the early 16th century came the development of the regular army (*see* ARMY) Discipline, the feeling of comradeship and soldierly honour were the qualities which marked out the Spanish army as the model for others to follow, and for more than a century the Spanish army maintained its prestige as the first in Europe The oldest regiments of the present Spanish army claiming descent from the *tercios* date from 1535 An officer whose regiment was reduced commonly took a pike in some other corps (*e g*, Tilly), the *señor soldado* was counted as a gentleman, and his wife and family received state allowances Nor was this army open only to Spaniards Walloons, Italians, Burgundians and other nationalities ruled over by the Habsburgs all contributed their quotas But the career of the old army came to an end at Rocroi (1643), and after this the forces began more and more to conform to the French model

There were never less than three Irish regiments in the army In 1808 the *Irlanda, Ultonia* (=Ulster) and *Hibernia* regiments had come to consist largely of native soldiers At that time the total forces numbered 137,000 men, but the part played by the Spanish standing army in the Peninsular War was certainly insignificant relatively to these figures But the result of this war and the continued civil wars of the 19th century was the destruction of the old army, and the present army of Spain still bears traces of the confusion out of which it arose In 1870, when conscription was introduced, and in 1872, universal service was proposed in its place (X)

Recruitment and Service.—Recruiting is on a national basis and military service, to which liability is universal, must be performed in person, with certain postponements for family, residential or educational reasons Reduction of the period of service with the colours to nine months is permitted for those who can afford to pay for the privilege The compulsory system is supplemented by volunteering between the ages of 18 and 21, the age at which compulsion is applied Military service is for 18 years Recruits spend two years with the colours Of about 47,800 recruits in 1927, about 38,700 were posted to the combatant arms, including 830 to the air force

Strength and Organization.—The budget effective strength of the army in 1927 numbered 113,434, including 13,434 officers The organization in the peninsula is in 16 mixed divisions, and the Balearic and Canary Islands each have an infantry brigade with garrison troops of the other arms in addition The largest cavalry formation is the brigade, of which there are five in the mixed divisions, which vary in their composition

Forces in Africa.—Recruits in the peninsula and islands for service in Africa (Morocco) number about 11,500 annually. The budget effectives of the army in Africa in 1927 numbered about 88,300, including about 3,100 officers There is a High Commissioner in chief command of the army in Morocco, with generals in command of the troops in Ceuta, Melilla, Larache and Tetuan Auxiliary forces include civil guards, carabiniers, etc, in the towns of the Morocco Protectorate The military air force in Morocco contains workshops, 3 groups of reconnaissance flights at Tetuan, Melilla and Larache, and a hydroplane base with two sea-plane flights at Melilla

Higher Command.—The king is the supreme head of the army He also presides over the council of national defence. The central administrative office of the army contains (a) a ministry of war with the usual departments and a special war archives office, (b) the general staff, responsible for training and preparation for war, (c) a supreme naval and military board, and (d) a central board (junta) to mobilize civil industries Under captains-general or other senior army officers there are 7 military commands in the peninsula (1) Madrid (2) Seville (3) Valencia (4) Barcelona (5) Saragossa (6) Burgos and (7) Corunna. The garrisons of the Balearic Islands (headquarters Palma de Mallorca) and the Canary Islands (headquarters Santa Cruz, Teneriffe), each under a captain-general, form separate commands.

The training centres for officers include a staff college, central musketry school, riding school, army medical academy and schools for infantry, cavalry, artillery, engineers and administrative (supply and transport) officers. There is also a central physical training school. Non-commissioned officers of 3 years service are given special facilities for obtaining commissions through the military academies Points for special notice are the embodiment of heavy tank units in the artillery, in Morocco (Ceuta and Melilla areas), the light tank units with the infantry (Larache and Melilla areas) and the employment of motor transport in Africa, specially in the engineer, transport and medical services, and for wireless telegraphy Reliance is placed upon fortifications, mostly of old type, for defence of the principal harbours and naval bases.

Army Air Forces.—The army air forces include an independent flying branch and a branch attached to army units A squadron contains 3 groups, each of 2 flights of 3 sections of 3 machines in flying condition The total force includes 3 fighter groups (6 flights), 9 reconnaissance groups (18 flights) and 2 sea-plane groups (4 flights). The army air force is distributed in the peninsula in a training squadron, Madrid, Seville and Leon squadron and Granada group, and sea-plane group The above-mentioned air force in Morocco is included in the total specified In addition to the aeroplane and sea-plane units, there is a balloon branch with headquarters, regiment and balloon battalion.

See also the League of Nations *Armaments Year-Book* (Geneva, 1928) (G. G A)

Navy.—The Spanish navy is small, but contains representative types of ships to be found in the fleets of greater sea powers These include —2 "Dreadnought" battleships, the "Alfonso Trece" and the "Jamie Primero," armed with 8 12" guns; 1 Aircraft carrier of 10,800 tons, attached to the Flying School for training purposes, 11 Cruisers and light cruisers, the most modern of which are the "Principe Alfonso," the "Almirante Cervera" and the "Miguel de Cervantes" of 7,850 tons, armed with eight 6" and four 4" guns and having a speed of 33 knots; 29 destroyers and torpedo boats; 12 submarines; 13 miscellaneous craft

Three cruisers of about 10,000 tons are to be built to replace the old ships. The seagoing fleet was reorganised early in 1928 and placed under the command of a Vice Admiral Personnel for the ships' companies is recruited by conscription

A Council of National Defence which includes a Minister of Marine and a newly-constituted General Directorate of Operations with a staff of naval officers under a vice admiral is responsible for the general direction of naval and military policy *See Brassey's Naval and Shipping Annual;* F Jane, *Jane's Fighting Ships* (annual) and H W Wilson, *Battleships in Action* (2 vols, 1926) (E A)

ECONOMIC AND INDUSTRIAL CONDITIONS

Economic Policy.—The most significant feature in the economic life of Spain is the marked movement towards nationalization. The beginning dates back to 1907, when a tentative step was taken towards the protection of national industries A stronger and more purely Spanish colour was shown in the Law on taxation of profits, which gave the first legal definition of a Spanish company This Law (of April 25, 1911) ruled that companies registered and domiciled in Spain were to be considered as foreign companies when (a) a sufficient number of the directors to form a quorum, and take decisions by themselves, were not Spanish; (b) when the legal managers of the business depend upon a foreign corporation or firm, either as employees or by contract and agreement, (c) when either from the name of the company or its advertisements or business negotiations it may be recognized that it acts under the instructions of a foreign corporation, (d) when the Spanish Administration receives authentic information that sufficient of the shares are in the hands of a foreign corporation to enable this latter to impose its will upon general meetings of the shareholders and in the management of the company

In 1917 another law for the protection of national industries was passed. In 1919 a revision of the Customs Tariff was ordered, and this began in 1920. The movement towards high tariff protection had commenced. In 1922 a new tariff was promulgated, which afforded very high protection indeed to Spanish industry.

A further move was made in 1924 by the Railroad Statute of July 13, which in some of its measures seems to be specifically directed against foreign companies. Under this Railroad Statute, transport rates are to receive the assent of the Superior Railway Council so that, in effect, the railroads now work under close Government supervision.

BY COURTESY OF GEERLINGS

A CHESTNUT VENDOR OF RONDA, AND A SPANISH GYPSY OF GRANADA

The march towards a more complete form of economic nationalization received a great impetus by the formation of the Primo de Rivera Government in Sept. 1923. This Government forged the nationalistic conceptions of the moment into a weapon for the nationalizing of industry in Spain. They received the willing aid of the industrial provinces, *i.e.*, Catalonia and Vizcaya, for Spanish economic nationalization is really a child of Catalonia and Vizcaya. Thus the present Government of Spain, by taking the lead in the nationalisation of industry and its protection by means of subsidies and high customs tariffs, has really applied a unifying force to the provinces to which more especially were attributed Separatist tendencies.

The Tariff Revision of 1928 is dictated by the same trend. To clear the way for a more complete revision the Spanish-British Commercial Treaty of 1922 was first amended, and by agreement between the two countries many consolidated customs schedules were abrogated.

The declared policy of the Government is to revise all existing commercial treaties which contain fixed or consolidated tariff rates, with the intention of replacing these rates by mutual most-favoured-nation clauses.

It is undoubted that the general policy formulated above has received the wholehearted support of the manufacturing and banking classes of the community. One instance where this satisfaction with the existing state of affairs is perhaps best evidenced is to be found in the prices of Government securities during the year 1927, the funds in general rising during the course of the year from 1 to 3 points.

Under a Decree of July 9, 1926, an Extraordinary Budget was instituted for public works, over a period of just over ten years, terminating at the end of 1936. The amount of money provided in this Extraordinary Budget was 3,538,000,000 of pesetas. Of this total 878,000,000 were to be devoted to naval constructional work, 632,000,000 to the Army, including aviation, while no less a sum than 1,600,000,000 pesetas was to be spent by the Ministry of Public Works on port and hydraulic works, roads and re-afforestation. The sum of 200,000,000 pesetas for expenditure on schools and other buildings was allotted to the Ministry of Education.

It must, therefore, be borne in mind in considering the public finances of Spain that, concurrently with the Ordinary Budget, there is going on an expenditure, over ten years, of 3,538,000,000 of pesetas on a public works constructional programme, while, in addition, there is in existence a five-year programme for the expenditure of sums up to 2,600,000,000 pesetas on railroads. This means that, if an average be cut across the two funds during the next five years after the institution of the Railway Fund, the sum of approximately 500,000,000 pesetas a year must be added for expenditure on railroads, and about 350,000,000 for expenditures on public works construction. Thus, during the first years, an extraordinary expenditure of 850,000,000 must be reckoned with, while after that date, and provided there is no extension to the railroad fund, an expenditure of about 350,000,000 pesetas yearly is provided under the Extraordinary Budget.

It is certainly the hope of the Spanish Government that these large sums will be provided by the Spanish money market on a low interest basis, and this expectation seems on the way to being realized. The successful issue of some thousands of millions of 3% tax-free bonds, at the price of 80 per hundred, made at the conversion of the Perpetual 4% Internal Loan in April, 1928, seems to show that the Spanish Government can secure money in Madrid for 4% and, so long as this is the case, it seems likely that the borrowing programme will be continued in order to provide for large expenditures on public works.

Conditions in Spain during the last few years have shown an improvement. Progress was helped by the political situation of the country, which evidenced a reaffirmation of assent to the present Government. The country has had the advantage of good crops in general, and the policy of industrial nationalisation has been carried a step further without any manifestation of ill effects. In 1927 the olive crop may perhaps be signalled as the best, and the wine output was very satisfactory.

Finance.—The conservatism of the Government in the matter of finances, in so far as regards the ordinary budget, coupled with the elasticity of the revenues, brought about a tremendous reduction in the deficit for the year 1927. The deficit was the very small one of approximately 24,000,000 pesetas, but it is the nearest approach to a balanced budget shown by Spain since the year 1909, and for that reason may be looked upon as a turning point in Spain's progress since the war.

The ordinary budget estimates for 1927 were as follows:

	Million pesetas
Total expenditure	3,139
Less revenue	3,073
Estimated deficit	66

The Minister of Finance, when publishing these estimates, admitted the possibility that the deficit on the ordinary budget might reach 200,000,000. The reality has proved to be much better than was expected, for, according to a provisional statement issued on April 8, 1928, the results were as follows:

	Million pesetas
Total revenue	3,218
Total expenditure on the ordinary budget	3,242
Deficit	24
Extraordinary expenditure	312·5
Total deficit for the year 1927	336·5

The reason for the excess of actual revenue over the estimates is to be found in the increases in taxation yield. The elasticity of the revenue from taxation is shown in the following table giving to the nearest million of pesetas the collections in 1925–26, the estimates for 1927, and the provisional returns of collections in 1927:

	Collected in 1925–26	Estimates 1927	Actual revenue 1927
Profits tax	358	357	394
Industrial tax	157	151	177
Royal dues	146	176	202
Land tax	285	313	336
Sugar	92	90	101
Stamp tax	251	300	313

The total revenue of 3,218,000,000 pesetas compares favourably with that of 2,964,000,000 pesetas for the completed year 1925–26. The expenditure of 3,242,000,000 pesetas is an excess of less than 3% over the estimates. This has been brought about partly by the decline in expenditure in Morocco, where only 74,000,000 pesetas were spent, in comparison with 176,500,000 pesetas in 1925–26.

The deficit for 1927 may be looked upon as a definite turn for the better in comparison with previous deficits, which were.—

	Million pesetas
1922–23	920
1923–24	576
1924–25	570
1925–26	608

Budget Estimates for 1928.—The expenditure was estimated at 3,257 million pesetas, made up of —

	Million pesetas
Permanent services	3,035
Temporary services	216
Liabilities and accounts	6
	3,257

Revenue is estimated at 3,258,000,000 pesetas, which leaves an estimated surplus on the ordinary budget of 1,000,000 pesetas This is an increase of only 40,000,000 pesetas over the revenues actually collected in 1927, so it seems probable that the 1928 estimates are on the conservative side The expenditure of 3,258,-000,000 pesetas is an increase of 16,000,000 over the amount spent during 1927 under ordinary budget headings

Public Debt.—The following table gives the different categories of the Spanish National Debt after the recent conversion of 4% Perpetual Internal Debt.

In Millions of Pesetas, Nominal

	In circulation on April 12, 1928
Internal 4%	5,261
External 4%	911
Redeemable 4%, 1908	131
Redeemable 5%, 1917	965
Redeemable 5%, 1920	1,267
Redeemable 5%, 1926, tax-free	225
Redeemable 5%, 1927, tax-free	3,547
Redeemable 5%, 1927, subject to tax	2,071
Redeemable 4½%, 1928, tax-free	500
Redeemable 4%, 1928, tax-free	1,098
Redeemable 3%, 1928, tax-free	2,034
	18,010

The annual service of interest and sinking fund is estimated at 846,000,000 Taking the revenues as estimated for 1928 at 3,258,000,000, it will be seen that debt services absorb 26% of the revenues.

Note Circulation.—The following figures give the note circulation and reserves at the close of the last three years —

Millions of Pesetas

	Note circulation	Gold reserve	Silver bullion and specie
1925	4,439·5	2,566 6	652 4
1926	4,339 2	2,592 0	675 1
1927	4,202 4	2,640 6	685·1

In the course of two years the notes in circulation have decreased by 237,000,000, while the gold and silver reserves have increased by 84,000,000 and 33,000,000 respectively It is not surprising, therefore, that the peseta exchange showed improvement.

Bank Clearings.—The settlements effected through the Madrid Clearing House showed a large increase in 1927 over previous years The figures in millions of pesetas are —

1924	12,779	1926	18,119
1925	14,136	1927	54,494

The increase in the total clearings has not carried with it a wider diffusion of the system of payment by cheque. The number of cheques dealt with in 1927 was less than in 1926. The Clearing House Committee sees cause for regret in this fact, and appeals for concerted propaganda to convince commercial firms of the advantages of cheque payments

Prices.—The general course of wholesale prices in 1927 was downwards, in agreement with the increase in the value of the peseta, as is shown in the following index numbers for foodstuffs and raw materials, compiled on a basis of 100 for the year 1913:

1927	172	1924	183
1926	181	1920	221
1925	188	1913	100

Spain's Foreign Trade.—Statistics published by the Council of National Economy show that the total volume of Spain's foreign trade during 1927 reached 4,481,000,000 pesetas, of which 2,586,000,000 are represented by imports and 1,895 millions by exports The following table shows the relation to the trade of 1926 and 1925.—

Totals to Nearest Million of Pesetas

	1927	1926	1925
Imports	2,586	2,154	2,249
Exports	1,895	1,606	1,585
Total	4,481	3,760	3,834
Inc or Decr in total trade	+722	−74	
Adverse trade balance	600	548	664

The imports of manufactured articles show by value and volume continuous increases over the three years, and an important increase is to be recorded in coal shipments to Spain, the bulk of the latter being of British origin

Of the 6,247 tons of ferromanganese imported, Great Britain shipped 3,874 tons, followed by Norway with 2,244 tons Scrap iron and steel entered Spain to the extent of over 100,000 tons, which compares with 57,000 and 94,000 tons in 1926 and 1925 respectively, Great Britain retaining the lead. Imports of fine carbon steels show a progressive increase since 1925, the 1927 figures being 1 721 tons, of which British firms supplied 610 tons Seven thousand three hundred tons of tinplates, or double the amount of 1926, were absorbed by the Spanish market; the United Kingdom, as usual, shipped the bulk, viz 6,837 tons

In the machine tool section Germany is again at the head of the suppliers, the imports from Great Britain being on the same level as those of the preceding year Textile machinery shows a slight falling off, the figures being 3,568 tons in 1927, 3,715 tons in 1926, and 3,903 in 1925 Great Britain's share has dwindled from 1,540 tons in 1926 to 1,116 tons in 1927. In motor-cycles Great Britain retains the lead, with 128 tons, followed by France, with 97 tons The total imports were 238 tons in 1927, 129 tons in 1926, and 94 tons in 1925, thus indicating a progressive improvement in the market for motor-cycles in Spain In the motor-car section the United States and France continue to be the chief suppliers.

In comparison with previous years, the imports of cotton piece goods have slightly declined, although the United Kingdom retains the lead in their supply. The same remark applies to the other textiles made of vegetable fibres, and to woollen piece goods

Exports of iron ore show an advance at 4 800,000 tons, as against 1,900,000 and 3,600,000 tons in 1926 and 1925 respectively. Great Britain absorbed 2 400,000 tons

Transport.—In July 1925 a railroad fund of 2,600 000,000 pesetas was sanctioned The railroads may secure advances from the State for the purpose of providing for capital expenditure The advances made from the fund are a charge upon the earnings of the company in the sense that a part of the earnings proportionate to the amount of capital advanced by the State is returned as its participation

The total extent of the Spanish railway lines at the end of 1926 was 16,200 km of which 11,750 km. were broad gauge, 4,224 narrow gauge and 16 km funicular railways

The general advance in transport facilities in the interior of Spain is reflected in the following short table —

Years	Locomotives	Wagons	Tonnage transported
1921	2,765	58,625	32,772,863
1922	3,220	67,766	39,910,285
1923	3,238	67,228	35,848,217
1924	3,325	69,760	43,302,632
1925	3,348	70,422	41,489,060
1926	3,519	72,792	41,869,668

Agriculture.—The agriculturally productive area of Spain is officially estimated at 94% of the total, but a large part of this is not cultivated. The area under cultivation is approximately 46% of the total, while about 48% is pasturage and mountain land. The remaining 6% is classified as unproductive for agricultural purposes.

The crop taking the largest acreage is wheat, followed by barley and other cereals. These occupy about 20,000,000 acres, being approximately 16% of the total area. About 6% of the total area is devoted to olives and the vine.

The mainstay of Spain's economic existence is its agricultural production. This fact has not been lost sight of by the Government inaugurated in 1923 by General Primo de Rivera. A vast number of proposals for stimulating agricultural production have been brought forward and put into execution.

Some of the legislation is interesting. For instance, on May 4, 1926, a tax of 10 pesetas to 100 kg. was levied on all oil manufactured from ground nut and sesame seeds, while the previous month imports of these seeds had been limited to 40,000 tons. Later on in the year importation was prohibited altogether. The idea in this case was to protect Spanish olive oil.

Legislation in the same year (May 12–29) instituted a fund of 25,000,000 pesetas for credits to wheat growers. On July 6, a minimum price for wheat was fixed. This had already been done in 1925. These two measures having proved inadequate, on July 9, 1926, the importation of wheat was again prohibited.

As a consequence of the resolutions passed at a conference held in Oct., 1926, a Royal Order of Dec. 11, 1926, established an Orange Committee whose mission was to develop the orange-growing industry. Later on, in April 1928, an attempt was made to form a syndicate of all the orange producers and exporters, but the movement did not meet with anything like unanimous adherence, and at the moment the proposal is in the air. On Jan. 7, 1927, a Royal Order provided for the inspection of oranges prior to shipment. This was a valuable move in the attempt to standardize fruit shipments from Spain, and should undoubtedly lead to great benefits for growers and exporters if the system can be extended and applied to all shipments.

WELL-TO-DO CASTILIAN VILLAGERS IN FÊTE COSTUME

In October, 1926, a Royal Decree established a Silk Commission for the purpose of developing silk worm culture in Spain. Poultry farming also formed one of the objects of Government solicitude, and a Royal Order of January 18, 1927, promulgated measures for its development.

On Feb. 18, 1927, a Royal Order was published providing for the grant of credits against crops of wheat, oil, wine, rice and wool. The underlying intention of this Order was to facilitate credits to small growers, and the maximum amount of credit to be granted to any one grower was raised from 5,000 to 10,000 pesetas.

A Raisin Committee was formed in June, 1927, with a central office at Denia. The duties of this Chamber are to promote production, export, and consumption of Muscatel grapes and raisins. A Grape Committee was established at Almería, whose duties are the protection of the trade in fresh grapes.

Export bonuses were granted in June, 1927, on rice exported during any one year up to a quantity of 20,000 tons.

In this multitude of measures for the protection and development of agriculture, the wine trade was not forgotten, and a Decree-Law of May 7, 1928, authorised credits on Spanish wines at 5% interest, up to 60% of the value.

Cotton-growing is still in an experimental stage, but results have been most marked, the crop rising from 860 tons in 1924 to 5,364 tons in 1926. This increase also is partially due to the encouragement of the Government.

To this summary of the legislative and other measures taken for the protection of agriculture during the last three years may be added that the Spanish Government earmarked 100,000,000 pesetas for re-afforestation in the Extraordinary Budget of 1926, and has recently created an Institute of Agronomic and Forestry Research and Experiment.

The following table gives the totals of Spanish agricultural production, to the nearest thousand of metric tons and hectolitres, for the years indicated:—

SPANISH AGRICULTURAL PRODUCTION
(*In thousands of metric tons or hectolitres*)

	1913	1926	1927
Wheat, m.t.	3,059	3,090	3,942
Barley ,,	1,497	2,096	2,008
Rye ,,	709	597	674
Oats ,,	368	547	569
Maize ,,	639	437	663
Rice ,,	223	320	309
Grapes ,,	2,953	2,770	4,612
Wine, hectolitres	17,105	15,754	28,325
Olives, m.t.	1,487	1,291	3,517
Oil, hectolitres	2,654	2,301	6,656
Sugar, Beet, m.t.	149	251	219
,, Cane, ,,	13	7	11
Oranges, m.t.	..	1,171	1,044

Mining and Minerals.—Second to agriculture is the mineral wealth of Spain which yields millions of tons of ore, principally for export.

Iron Ore output sank over 7,500,000 tons from 1913 to 1926, although the 1926 figures are hardly comparable because during that year the smelting works in Great Britain were obliged to reduce purchases. The general cause of the decrease in iron ore output is the gradual exhaustion of the principal mines yielding the better class of ores, whilst the industry in general is somewhat hampered by high costs of production.

The output of Copper shows a steady increase, the production in 1927 being nearly double the 1913 output.

The following table shows the Spanish Coal output in metric tons for the last few years, and a comparison is made with 1913, the year preceding the outbreak of the World War:—

(*In Thousands of Metric Tons*)

	1913	1923	1926
Anthracite	233	299	403
Pitcoal	3,783	5,672	6,133
Lignite	277	394	400
Total	4,293	6,365	6,936

The figures show an extremely rapid rise in production, the apex being attained in 1926, the year of the British coal strike.

In 1924 the Railway Statute was promulgated (July 12), and the Government took advantage of this law to revert to the subject of the consumption of Spanish coal. The policy of subsidies was codified and regularised in October, 1925. These somewhat tentative movements culminated in February, 1926, in legislation made with the idea of supporting the Spanish coal-mining industry, and helping it to expand still further by enforcing the use of Spanish coal up to a very high percentage of the total consumption on the railroads and in subsidized industries. The percentage to which Spanish coal must be used in the case of railroads running express passenger lines is 85% of the total con-

sumption, whilst in the case of other railroads coming under the Railroad Statute the proportion is 90%. Industries have been classified in various ways, and upon them have been imposed certain proportions for the use of Spanish coal, which, however, do not reach the percentages enforced upon the railroads.

The annual average imports of British coal into Spain before 1925 was something over one and a half million tons British exports in 1927 were very much in excess of that figure, and as a consequence of the coal stoppage in Great Britain the variation between the 1926 and 1927 figures was extremely great, the 1926 exports being 785,000 tons, whilst the 1927 figures were 2,361,000 tons. The agitation on the part of the Spanish coal owners in the early part of 1928 was directly due to the very large imports of 1927.

A MAN AND WOMAN OF THE PROVINCE OF LEON, SPAIN, IN CHARACTERISTIC DRESS

The output of lead ore has been affected by the drop in the price of the metal, but both miners and smelters have managed to maintain their production, and lead, on the basis of its value, occupies the second place in ore production A Consortium of Lead Producers was created by a Royal Decree of March 9, 1928 The Consortium is composed of the Arrayanes Mine, the lead-mining Syndicates of Linares-Caroline and Cartagena-Mazarrón, and such other concerns engaged in the mining, smelting and working of lead as may apply for admission It controls the purchase and sale in Spain of all the lead in bars, tubes and sheets required by the national market.

The production of copper ore and of ferro-cupreous pyrites has been steadily improving during the last three years, and the output of electrolytic copper and blister has likewise increased

Zinc ore was produced in increased quantities in 1926, and the quantity of zinc smelted has increased A similar movement in mercury and metallic quicksilver is also to be recorded

The production of superphosphates is becoming more important in Spain, rising from 185,000 tons in 1913 to 828,000 tons in 1926 This increase in production marks the progressive rise in Spanish demand.

Hitherto the production of potassium salts in Spain has been insignificant, but in 1926 it occupied the sixth place, in so far as regards value, amongst all the minerals produced in Spain.

The Government has reserved for itself 378,335 hectares of land bearing these salts, some 93,675 having been registered by private individuals Report states that the layers are from two to five metres thick The production in 1926 was 80,598 tons.

There is an increasing tendency to legislate with a view to restricting the exploitation of the mineral wealth of the country to Spaniards

Figures giving the ore output for the last three years available (1924–26), together with those for 1913 as a basis for comparison, are given below:—

A—ORE OUTPUT

(In thousands of metric tons)

Years	Coal including lignite	Lead including argentiferous	Copper and pyrites	Iron and pyrites	Zinc	Mercury	Sulphur	Manganese
1913	4,293	303	2,289	10,789	117	20	63	22
1924	6,539	190	1,900	5,222	117	15	65	21
1925	6,520	208	3,681	4,462	168	23	62	36
1926	6,936	216	3,937	3,195	201	30	65	45

B—MINERAL AND METAL OUTPUT

(In thousands of metric tons)

Years	Iron and steel	Lead	Coke and briquettes	Super phosphates	Copper	Cement	Zinc	Mercury
1913	667	199	1,081	186	31	512	6	1 0
1924	1,128	142	1,475	696	36	917	13	0 9
1925	1,159	154	1,549	723	30	1,136	15	1·0
1926	1,100	150	1,519	829	48	1,183	16	2·0

Industries.—Every department of Spain's economic life shows the effects of the World War period Impetus was given to the formation of industries which were either non-existent before the war or in an embryonic state. These were put through a hothouse forcing period with the idea of supplying the Spanish market as well as the Allies

With the return to conditions in which industry was obliged to compete in Spain itself with the foreign industries which had catered for Spain before the war, there spread a "malaise" which affected the whole industrial structure of the country, and manufacturers assisted in bringing into being a thorough-going campaign for the protection of industry

Notwithstanding this campaign, many Spanish industries feel that they are not yet sufficiently secure from foreign competition in their own market, and there seems every likelihood that the protective movement will be carried even further.

The movement in the rate of exchange since the war has adversely affected the ability of local industry to compete, both at home and abroad The fall in the value of the peseta, and its more recent return to a figure of about 29 pesetas to the pound sterling has increased the gold cost

The above explains from the economic side the force of the campaign for higher customs duties in Spain today. It also shows that, upon the whole, there seems little likelihood of any slackening in the movement

Hydro-electric Development.—A convention between Spain and Portugal, delimiting their respective rights in the falls of the River Douro, was signed on Aug 11, 1927, and ratifications were exchanged in Lisbon on Aug. 22 A company called the "Sociedad Hispano-Portuguesa de Transportes Eléctricos" has been awarded the concession for the exploitation of the Falls

No official Spanish statistics dealing with the production of electric energy are available, and it is therefore difficult to indicate with any degree of certainty the actual waterpower utilized Nevertheless, it is possible to estimate the power derived from waterfalls in exploitation at about 1,300,000 h p., and the production of electric energy at over 1,000,000 k w , while according to expert opinion the total power latent in Spanish waterfalls is about 7,500,000 h p.

The production of electric energy has extended to the whole of Spain, facilitating the conversion of steam-driven railways into lines worked by electricity Small industries are springing up in villages where previously motive power was not available It appears that in the near future a scheme of national distribution of electric energy is to be introduced

Metallurgical.—No statistics are published with regard to industrial production, save in the case of the metallurgical industries. It is not, therefore, possible to make a detailed study of the general advance which is taking place in Spanish industry, but it is beyond doubt that such progress is constant.

The value of the output of the metallurgical industries in 1913 was 302,600,000 pesetas In 1918, a year of prosperity and high prices, it reached the sum of 841,100,000, and in 1926 it attained 918 900,000 pesetas

The manufacture of fine steels has improved considerably, and in 1927, with the collaboration of foreign experts, the production of certain alloys of special steels was begun.

The construction of rolling stock for railways has assumed larger proportions than previously in Spain, and this industry shows positive prosperity Electrolytic copper and aluminium are

also being produced in considerable quantities.

Chemical.—The manufacture of chemicals shows notable progress. Pharmaceutical specialities are placed on the market which compete with those from abroad, and dyestuffs of Spanish manufacture are every day more current.

Aeroplanes.—The branch of industry which perhaps has made the greatest progress is the building of aeroplanes and hydroplanes. The firms "La Hispano" of Guadalajara; "Construcciones Aeronauticas, S.A.," of Getafe and Cadiz; Loring of Carabanchel Bajo, and "La Hispano-Suiza" and "Elizalde" of Barcelona, hold licences for the construction in Spain of Aeroplanes and Hydroplanes, both metal and ordinary types, of the marks Breguet, Dornier, Fokker, DeHavilland, Hispano-Suiza, Loring, Lorraine, Neuport and Potern, and are capable of constructing more than 600 machines annually.

Labour.—The following table regarding strikes shows clearly the improvement in the industrial situation since the present Government came into power in September, 1923:

Strikes

Years	No. of strikes	Workers affected	Workers on strike	No. of days lost
1920 . .	1,060	264,080	244,684	7,261,762
1921 . .	373	98,615	23,691	2,802,299
1922 . .	484	167,123	119,417	2,672,567
1923 . .	465	159,784	120,568	3,027,026
1924 . .	165	40,639	28,744	604,512
1925 . .	181	71,323	60,120	839,934
1926 . .	96	31,508	21,851	247,223

The public works undertaken by the Government under the extraordinary budget have given rise to an unusual demand for road rollers, cranes, excavators, and other machinery, keeping the iron and steel industries and the cement works fully occupied. So long as the expenditure on public works of several hundred million pesetas annually continues, the prosperity of these branches of Spanish industry is assured.

ARCHAEOLOGY

It is still impossible to introduce any accurate chronology into the prehistory of Spain. Before the Roman pacification in the 2nd century B.C. with its certain dates and events lie a couple of centuries of Punic penetration from Carthage; still earlier we know of the coasting voyages of Greek traders along the Mediterranean shore, and catch some glimpse of the Iberian civilization with which these Greeks came into contact; but all this brings us only into the 7th century B.C. Perhaps for several hundred years before the advent of the Greek ships there had been Phœnicians, mainly from Tyre and Sidon, who had maintained trading-posts along the southern shore of Spain and had sailed through the Gibraltar Straits to Cadiz on the Atlantic. Then the perspective of years lengthens out immeasurably and we step back, not by centuries but by thousands of years, through neolithic into palaeolithic times, when some type of men—we cannot guess what blood they were of or what form of language they knew—hunted the beasts of those early days and decorated with marvellously fine likenesses of these animals the inner walls and roofs of deep caverns.

Palaeolithic Spain.—These cave-paintings rank among our most impressive discoveries from the past. There can be no doubt of their vast antiquity, since they certainly represent animals of the late quaternary geological period and are engraved upon bones which are surely identifiable as those of animals now long extinct. Nor can there be much dispute about the extraordinary veracity and vivacity with which wild horse and bison, hind and stag, ibex and ox and boar are delineated with little save their outline and with no visible hesitation of stroke.

The best known of the Spanish caverns and one of the first to be discovered is Altamira near Santander. The publication of its contents by Cartailhac and the abbé Breuil (Monaco, 1906) is the best introduction to the study of palaeolithic Spanish archaeology. Other important sites are Hornos de la Peña, Pasiega, and Castillo in the province of Santander; Basondo in the province of Biscay; and Pindal, Buxu and La Peña in Asturias. Palaeolithic decorated caverns are largely confined to the small mountainous area in the north which extends from the westernmost Pyrenees through the coastal hills beyond Santander. They may therefore be justly termed Cantabrian. Elsewhere, however, beyond the Spanish border, the same type recurs, chiefly on the northern slopes of the Pyrenees and in the region of the Dordogne in southwestern France. These three districts—the one in northern Spain, the two others in southern France—are inseparably allied and were products of contemporary cultures. In other parts of Spain, where caves are little more than open rock-shelters, there has been found a distinctively different art.

Prehistorians therefore speak of "cave art" and "rock-shelter art," and distinguish sharply between Cantabrian and East-Spanish palaeolithic. During the last 20 years there has been great activity in the exploration and elucidation of this second group. Except that the fauna of the paintings here implies a slightly warmer climate, much the same series of animals are rendered in much the same style; but intimately combined with them appear weirdly represented men and women—a subject almost completely neglected by the Cantabrian cave artists. Often the men are armed with bow and arrow and shown in pursuit of their quarry; but whereas the beasts are naturalistically correct in the surprising palaeolithic manner, some of the huntsmen with threadlike limbs more nearly resemble the praying mantis, while others with sudden protuberances of calf or thigh suggest unevenly inflated rubber toys. The women, in long flounced petticoats very remotely suggestive of the elegant ladies of Minoan Crete, seem to take part in dances and conversations, poorly visualized and crudely rendered. This striking combination of a naturalistic animal art with geometrically conventionalized, highly primitive human representations is a phenomenon of great significance, since the groupings and actions of the men and women are almost as clearly allied to palaeolithic rock-drawings in north Africa as the ibexes and stags, horses and oxen and bulls are allied to the cave-paintings of Cantabria. As in historic, so in prehistoric times, the destiny of Spain must have been a succession of invasions, now from the north, pouring round or over the Pyrenees, now from the south out of Morocco and Algeria. The most important sites of the East Spanish group are Cogul by Lerida, Valltorta in Castellón, Albarracin by Teruel, Alpera and Mortaja in Albacete, and Cantos de la Visera in Murcia—all characteristically within two or three days' journey afoot from the sea.

Neolithic and Bronze Age Spain.—The Neolithic Age in Spain testifies to a wholly different condition of mankind. Perhaps it is too ingeniously simple to ascribe the naturalism of palaeolithic art to a race of hunters and the geometric conven-

tionalism of the neolithic to a race that tilled the soil. A fairly uniform culture spread over the entire peninsula; for the rock-shelters with neolithic drawings have a very wide distribution and show a striking similarity. They have almost no pictorial attraction and often more resemble picture script than actual illustration. The pottery finds are the great archaeological aid to neolithic chronology; and the occurrence of some of the conventionalized devices of the rock-paintings upon pottery which can with certainty be assigned to the transition from neolithic to the Early Bronze Age puts the general epoch of this culture beyond doubt

A closer comparison of ceramic types shows that beneath this superficial uniformity there lies sufficient diversity to warrant many subdivisions. Chief among these is the clear distinction between the more indigenous central and the south-eastern or "Almeria" culture which was probably under African influence and may actually have been the nucleus from which the true Iberian culture developed. In late neolithic times the more extensive central culture exhibits a distinctive and striking bell-shaped (the so-called "campaniform") pottery. At this time it is likely that there was some exportation of copper and silver from Spain to the nearest of the Mediterranean islands, since there are ceramic affinities with finds of the "aëneolithic" period (or Stone-and-Copper Age, lasting in Spain from about 3000 to 2500 B C) in the Balearics and in Sardinia and Sicily. The peculiar megalithic structures in these parts, such as the *talayots* of the Balearics (*q v*), the *nuraghi* of Sardinia (*q.v*), the underground chambers of Malta, are fairly well paralleled by megalithic grave structures in Portugal and Spain But there is as yet no certain proof of intercourse between the eastern and the western basins of the Mediterranean for these early times.

Somewhat after 2500 B C. the Bronze Age displaced the aeneolithic without apparent interruption; but still the Aegean influence, which can be proved to have reached Sicily and southern Italy, failed to extend as far as Spain If anything, the Bronze Age marks a retrogression in the civilization of Spain, where there has yet been no archaeological discovery to indicate a powerful or wealthy Bronze Age culture even remotely comparable to that of Crete or the eastern Mediterranean lands.

Tartessos.—Herodotus (iv 152) narrates the adventurous voyage of a Greek sailing-ship from Samos, which was driven by storm past the pillars of Herakles and "at last reached Tartessos. This trading-town was in those days a virgin port unfrequented by merchants, and the Samians in consequence made a greater profit than any Greeks before their day" This event supposedly took place about 630 B.C During the century thereafter, Tartessos was certainly frequented by trading vessels of the Ionian Greeks of Phocaea in the Bay of Smyrna. It has been maintained that this rich Spanish city on the Atlantic was the Tarshish of the Old Testament, which "with silver, iron, tin and lead" traded in the fairs of Tyre (Ezekial xxvii. 12).

Yet the modern search for Tarshish-Tarsis-Tartessos has failed. The German archaeologist Adolf Schulten after several campaigns regretfully admitted in 1926 that the mysterious city must lie deep under river and below the groundwater level.

The Iberians.—The whole of the peninsula was sometimes called Iberia by ancient writers; but the true focus of the Iberian civilization was the south-eastern corner of the land. Here a stock out of north-east Africa (Oran?) and therefore probably Hamitic (Berber?) may have been infiltrating ever since the aëneolithic days of the Almeria culture (*c.* 3000 B C.). They were probably racially akin to the Tartessians, who must therefore have also been African invaders. We become completely certain of their presence towards the end of the Bronze Age and, some centuries later, can trace the diffusion and inland penetration of their culture until it was finally absorbed by the Roman civilization almost as late as the time of Christ. Roman writers describe the typical Iberians as dark complexioned, with unkempt hair, small of face but with the cheekbones emphasized and the lower lip prominent, small-framed, alert and wiry. Iberian bronzes display them as riders of horses, and we know what their swords and daggers, spears and other weapons were like. The women are represented sometimes as wearing a singlepiece cloak drawn up over the head from the shoulders like a *mantilla* or shawl, and sometimes with a short, hooded garment which flares out below the waist and often has swallowtail sleeves We may judge of their jewellery and their headdresses from the famous sculptured bust, the "Lady of Elche," now in the Louvre. Iberian art was rude but vigorous, with a leaning toward sculptured animals of stone and human figurines in bronze. The pottery was decorated with simple linear themes, artistically of no particular distinction, until Greek examples offered more sophisticated decorative motives to copy The best Iberian art comes from the provinces of Murcia and Albacete in the south-east, where the Greek influence was strongest. The Iberians lived in walled towns The cyclopean masonry in the bottom courses of the great walls of Tarragon is indubitably a remnant of an old Iberian stronghold Tartessos and Massia (now Cartagena) were similarly enclosed; but the Carthaginians completely destroyed both of these cities, making Gades (now Cadiz) take the commercial place of the former and refounding the latter as Carthago Nova. Behind this seaboard fringe of Tartesso-Iberians the high-lying interior was in the possession of a variety of indigenous peoples of whom we have no clear knowledge except that, along with Catalonia, they passed through an Early Iron Age (or "Hallstadt" phase) and were at last completely submerged during the 6th century B C by an invasion of Celtic tribes who poured through the Pyrenees by the Pass of Roncesvalles and took possession of Castile This Celtic invasion may with full justice be called an historical event We can date its occurrence within a few decades, define its source, follow its spread, and perceive its results. In the extreme northern mountain lands the earlier inhabitants managed to preserve their individuality in the face of this Celtic irruption It has even been argued that the Basques, who maintain customs and a language whose isolation is a mark of extreme antiquity, are ultimate descendants of the palaeolithic Cantabrian folk which produced the cave-art so many thousand years earlier. Elsewhere, during the pre-Roman times, we find Celtic tribes (Beribraces, Sefes, Cempsos) in possession of the land.

Such is the ethnic picture during the 6th and 5th centuries B C. With such a Spain the Ionic Greek traders now came into contact, in rivalry with the Carthaginians who had fallen heirs to the century-old Phoenician exploitation of these western marts Neither the Phoenicians nor the Carthaginians left any permanent mark upon the land, while the Greeks influenced it profoundly. Ships from Tyre and Sidon may have traded beyond the Straits and in Cadiz at least as early as the 9th century B C ; yet modern archaeology, which has located and excavated Greek and Iberian and Roman towns, has not laid bare a single Phoenician settlement or found more important Phoenician remains than the odds and ends of trinkets and jewels and similar articles of barter The inference is clear that, except perhaps at Cadiz, the Phoenicians built no towns, but had mere trading-posts and points of call

The Greeks in Spain.—The Greeks, on the other hand, founded true colonies along the east and south coasts, where unmistakable traces of their settlements have survived The sites of Hemeroskopeion (at the modern Calpe) and Mainake (at the mouth of the Rio de Velez near Malaga) have been identified, though not yet excavated; and Emporion (now Ampurias, on the Pyrenean east coast near the French frontier) has been systematically dug, revealing a fortified town with strong gates and walls, streets more or less at right angles, remains of houses, and a shrine of Asklepios with a cult statue of the god.

While there is almost nothing in Iberian art ascribable to Phoenician or Punic influence, the art of the Greeks had indisputably a revolutionary effect. A collection of sculptures found at Cerro de los Santos in the province of Murcia, and now in the Madrid Archaeological Museum, is a hybrid of archaic Greek and Iberian art Fragments of Ibericized Ionic Greek architectural mouldings have been discovered in the same region, and the pottery from Elche and the surrounding districts is full of unmistakable borrowings from the ornamental repertoire of Greek vases The earliest Iberian money was coined in direct imitation of Greek types of the 4th century B C. Archaic Greek bronzes discovered in many parts of Murcia and Alicante, and the actual

material traces of the Phocaean colonies tell us that the Greeks were once in this part of Spain.

Elsewhere in the Mediterranean this period is covered by the written chronicles of the ancient historians; but the records for Spain are extraordinarily meagre. We hear no more about Tartessos after the 6th century B.C. Instead, Greek sources of the 5th century begin to speak of the whole Tartesso-Iberian region as Iberia; and recent archaeological exploration has confirmed this emphasis upon the Iberians and established them as the great civilizing force of that time in ancient Spain.

Spain Under the Carthaginians.—During the 4th century B.C. the Carthaginian encroachment reached most of the Iberian homeland, the Greek contact was broken, and the Greco-Iberian culture in Murcia waned. But in recompense, and probably under the pressure of this Punic expansion, the Iberian penetration of the interior gathered great headway. During the 3rd century B.C. the most flourishing Iberian centre in Spain is the valley of the Ebro, where in the 5th century there had been no Iberian settlements whatever; and Greek writers of the time no longer refer to the Castilian uplands as Celtic but as "Celtiberian." Recent excavation has confirmed this gradual Iberianization of almost the whole of pre-Roman Spain. Particularly of Numantia, and largely as a result of the careful and systematic work of Prof. Schulten in laying bare the sites of the Roman and Celtiberian encampments there, an extensive insight into this Iberianized Celtic culture of the 3rd and 2nd centuries B.C. has been gained.

The Romanization of Spain.—When the Romans began their efforts to Latinize the land after the close of the Second Punic War (201 B.C.) they found not a Celtic civilization like that of Gaul, but an Iberian culture of the general type which the Greeks had encountered and influenced before them. The dramatic story of Scipio and the capture of Numantia in 133 B.C. indicates with how much bloodshed and violence this Roman pacification was attended. However, the archaeological in contrast to the historical evidence shows that the two civilizations must have endured side by side for more than a century and suggests a more tolerant penetration and absorption. The latest sculptures from Cerro de los Santos, though still Iberian in style, borrow Roman statuary motives. In other regions true Iberian pottery is often found mixed with thoroughly Roman ware (*terra sigillata*). Iberian jewellery and gold have been found amid Roman surroundings; and most of the coinage bearing in Iberian script the names of Iberian towns dates from after the Roman conquest.

The archaeological remains of fully Romanized Spain are abundant, but show the monotony of a provincial art which has nothing to stimulate it into new forms of its own. There is no obviously and distinctively "Spanish" flavour in the architecture and sculpture of these times. The spirit which seems to distinguish mediaeval or modern Spain from the rest of Europe may or may not contain a recrudescence of Tartessian or Iberian or Celtiberian mentality. With the final Romanization of the land these older cultures were supplanted completely.

HISTORY TO A.D. 406

Primitive Inhabitants.—The origin and character of the early inhabitants of the Peninsula are obscure. We must await the result of further excavations of prehistoric sites and further inquiries into the native inscriptions before we can hope for much certainty. The Romans mention three races: Iberians (in the east, north and south), Celts (north-west) and Celtiberians (centre). The use to-day of the strange and ancient Basque tongue on the western slopes of the Pyrenees and in Vizcaya (Biscay) suggests that the Iberians may have been an older people than the Celts and alien from them in race. On the other hand, numerous place-names show that parts of the Peninsula were once held by the Celtic-speaking tribes who probably also inhabited the greater part of the area which is now France for several millenniums before the current era.

Earliest Historic Period.—The Phoenicians had possibly reached Spain by the 11th century B.C. One of their earlier foundations, Gades (now Cadiz), has been called the oldest town in the world (or in Europe) which has kept a continuity of life and name from its first origin. But their exploitation of the Peninsula dates principally from after the rise of Carthage (*q.v.*). Carthaginian "factories" were planted on many Spanish coasts: a Nova Carthago (New Carthage, mod. Cartagena) formed a Carthaginian fortress with the best harbour of south-eastern Spain. The expansion is attributed chiefly to the second half of the 3rd century B.C., and to the genius of Hamilcar Barca, who, seeing his country deprived by Rome of Sicily and Sardinia, used Spain, not only as a source of commercial wealth, but as an inexhaustible reservoir of recruits for the Carthaginian armies. But Rome too needed the Spanish men and mines, and, in the second Punic War, drove Carthage finally and completely out of the Peninsula (201 B.C.).

Roman Spain.—The Romans divided Spain into two *provinciae*, Hispania Citerior, that is, the northern districts which were nearer to Italy, and Hispania Ulterior, the south. To each province was sent yearly a governor, often with the title *proconsul*. The commands were full of military activity. The south, indeed, notably the fertile valley of Andalusia, the region of the Guadalquivir (*Baetis*), then called Baetica, was from the first fairly peaceful. Italian veterans or Spanish soldiers who had served for Rome were settled at Hispalis (Seville) and at Carteia near Gibraltar, and a beginning was made of a Romanized provincial population. But in the north, on the high plateau and amidst the hills, there was incessant fighting throughout the greater part of the 2nd century B.C., and indeed in some quarters right down to the establishment of the empire. In the long struggle many Roman armies were defeated, many commanders disgraced, many Spanish leaders won undying fame as patriot chiefs (*see* NUMANTIA). But the struggle could not be given up without risk to the lands already won. So the war went on to its inevitable issue. Numantia, the centre of the fiercest resistance, fell in 133 B.C. (*see* SCIPIO), and even northern Spain began to accept Roman rule and Roman civilization. When in 80–70 B.C. the Roman Sertorius (*q.v.*) attempted to make head in Spain against his political enemies in Rome, the Spaniards who supported him were already half Romanized.

There remained only small groups of unconquered tribes in the northern hills and on the western coast. Some of these were dealt with by Julius Caesar, governor here in 61 B.C. Others, especially the hill tribes of the Basque and Asturian mountains, were still unquiet under Augustus. By the days of Cicero and Caesar (70–44 B.C.) the southern districts, at least, had become practically Roman: their speech, their literature, their gods were wholly or almost wholly Italian. Gades was the first city outside of Italy which obtained a municipal charter as *municipium*, without the usual implantation of Roman citizens.

Imperial Spain.—Under Augustus (or possibly Tiberius) there was a reorganization. Henceforward there were three provinces: (*a*) the north and north-west, the central tableland and the east coast as far south as New Carthage, that is, all the thinly-populated and unquiet hill country, formed the province of Tarraconensis with a capital at Tarraco (Tarragona) under a

legatus Augusti pro praetore with a legion (VII. *Gemina*) at Leon and some other troops at his disposal; (*b*) the fertile and peaceful west formed the province of Lusitania, very roughly the modern Portugal, also under a *legatus Augusti pro praetore*, but with very few troops, (*c*) the fertile and peaceful south formed the province of Baetica, under a pro-consul nominated by the senate, with no troops These divisions (it will be observed) exactly coincide with the geographical features of the Peninsula Substantially, they remained till the end of the empire, though Tarraconensis was broken up at different dates into smaller and more manageable areas Augustus also accelerated the Romanization of the land by planting in it many municipalities (*coloniae*) of time-expired veterans (*e-meriti*) such as Augusta Emerita (mod. Mérida), which still possesses extensive Roman ruins About this time imperial finance agents (*procuratores*) were appointed to control the revenues and look after the mines, which became Imperial property, while a special *praefectus* administered the Balearic Islands. The iron and also the copper, silver and lead of Spain were well known it was also (according to the elder Pliny) the chief source whence the Roman world obtained its tin. Its olive-oil was superior to that of Italy But commercial prosperity characterized many districts of the empire during the first two centuries of our era Spain can boast that she supplied Rome with almost her whole literature in the silver age The Augustan writers had been Italians. Their successors were Spaniards—the younger Seneca, Lucan, Martial, Quintilian, besides a host of lesser lights By-and-by the impulse of the opening empire died away and with the 2nd century the great Roman-Spanish literature ceased. Of statesmen the Peninsula was less prolific Though the emperor Trajan and his relative and successor Hadrian, were born in Spain, both were of Roman stock and Roman training. The 3rd and 4th centuries saw a decline in prosperity The confiscations of Septimius Severus and the ravages of barbarians in the middle of the 3rd century have been adduced as causes. But, though we need not doubt that the decline occurred, we can hardly determine either its date or its intensity without careful examination of the Roman remains of Spain While many of the best Roman ruins—such as the aqueduct of Segovia or the bridge of Alcantara—are older than 200 A D. others are probably later, and indicate that prosperity continued here, as it did on the other side of the Pyrenees, till the later days of the 4th century—perhaps indeed till the fatal winter's night in 406–7 when the barbarians burst the Rhine frontier and flooded Gaul and even Spain with a deluge from which there was no recovery (F J. H; G M)

FROM A.D. 406 TO THE CONQUEST OF GRANADA

The Barbarian Invasion.—With the irruption of the Vandals, the Suevi and the Alans, the history of Spain enters on a long period of division and confusion which did not end even with the union of the chief kingdoms by the marriage of Isabella and Ferdinand at the close of the 15th century. The function of the barbarians everywhere was to cut the communications of commerce, and the nerves of the imperial administration

This function was effectually discharged in Spain by the Vandals and their associates, who plundered far and wide, and then by the Visigoths, who appeared as the *foederati*, or duly commissioned defenders of the Romans. The first-comers were not numerous enough to establish a rule of their own When in 428 Gaiseric, king of the Vandals (*q v.*), accepted the invitation of Bonifacius, the count of Africa, and passed out of Spain to found the Vandal kingdom of Carthage, his whole horde numbered only 80,000 persons, including old men, women and children, and runaway slaves who had joined him. There is probably some truth in the assertion of Salvian that many of the subjects of the empire preferred poverty among the barbarians to the tyranny of the imperial tax collectors. This would be pre-eminently the case with the smaller landowners who formed the *curiales*, and who were in reality serfs of the fisc, for on them fell the main weight of taxation, and they were confined to their position by oppressive laws. The great landowners who formed the *ordo senatorius* had almost as much to fear from the agrarian insurgents known as *bagaudae*, who are indeed found acting with the Suevi, as from the barbarians In the north the Asturians and Basques, the least Romanized part of the population, appear from the beginning of the age of barbarization as acting for themselves In the mountain country of Cuenca, Albacete, and the Sierra Nevada the natives known as the Orospedans were entirely independent in the middle of the 6th century. But if there lay in this revival of energy and character the germs of a vigorous national life, for the time being Spain was thrown back into the state of division from which it had been drawn by the Romans—with the vital difference that the race now possessed the tradition of the Roman law, the municipalities, and one great organization in the Christian Church

No help was to be expected from the empire Unable to aid itself it had recourse to the Visigoths (*see* GOTHS) Ataulphus (*q v.*) the successor of Alaric, and husband of Placidia, daughter of the emperor Theodosius, whom he had married against the wish of her brother Honorius, entered Spain in 412, as the ally of the empire He was murdered in 415, but after the speedily ensuing murder of his murderer and successor Sigeric, Wallia (415–419), who was elected to the kingdom, continued his work He destroyed the Alans, and drove the Vandals and Suevi into the north-west Then he handed Spain back to the imperial officials, that is to say, to weakness and corruption, and marched with all his people into the Second Aquitaine, the south-west of modern France, which had been assigned to them by Honorius as a home and a reward. From this date till the very end of the reign of Amalaric (511–531), the seat of the Visigothic kings was at Bordeaux, or Toulouse or Narbonne, and their main interests were in Gaul Southern Spain was overrun and plundered by the Vandals before their departure for Africa In 456 Theodoric II. (453–466) entered Spain as ally of Avitus, whom he had himself raised to the empire in Gaul He defeated the Roman senators of the Tarraconensis and the Suevi, putting their king to death, and advanced as far as Mérida Majorian (457–461), the last capable emperor of the West, proposed to make Spain the basis of his attack on the Vandals at Carthage till his fleet was destroyed by them in the harbour of Carthagena The fratricidal murderer and successor of Theodoric, Euric (466–485), followed his brother's policy in Spain With the extinction of the Western empire (476 or 479) the kings of the Visigoths became more and more the representatives of authority, which they exercised on Roman lines, and with an implied or formal deference to the distant emperor at Constantinople. After the defeat and death of Alaric II (485–507) at Vouillé the shattered Visigoth power was preserved from destruction at the hands of the Frankish king Clovis (*q v*) by Theodoric, the Gothic king of Italy. But on his death the advance of the Franks began again Amalaric (507–531) fled from Narbonne, to meet the usual violent end of a Visigothic king at Barcelona.

The Visigothic Kingdom.—The line of the Visigothic kings of Spain begins, strictly speaking, with his successor Theudis (531–548), an Ostrogoth appointed by Theodoric to act as guardian of Amalaric He had acquired great possessions in the valley of the Ebro by marriage with a Roman lady It was a Government, and not a people, which was established in Spain with Theudis The Visigoths had been much Romanized during their establishment in Gaul Their monarchy was elective Until the death of Amalaric the choice was confined to one family, but he was the last of his line The kings tried to make the Crown hereditary, and the nobles, Visigothic *seniores*, and Roman *senatores* seized every opportunity to keep it elective. Of the 23 kings between Theudis and Roderic five were certainly murdered, one was deposed, and three were tonsured by tricks or open force.

The administration which these kings of unstable authority had to direct was essentially the Roman system. The great owners, whether nominally Visigoth or nominally Roman—*seniores* or *senatores*—continued to enjoy all the privileges and exemptions of the *ordo senatorius* in the last days of the empire. They lived surrounded by multitudes of semi-servile *coloni*, or farmers, bound to the soil, of actual slaves, and of *buccelarei*, who were free swordsmen to whom they gave rations (*buccelatum*, soldiers' bread, or *buccella*, a portion). The *curiales* remained as before

the victims of the fisc.

Theudis, who made his headquarters at Seville, endeavoured to complete his mastery of the diocese of Spain by occupying Mauritania Tingitana, but he was defeated by the imperial officers at Ceuta. He was in due course murdered at Seville by Theudigisel (548–549) who was himself promptly slain. The reigns of his two successors, Agila (549–554) and Athanagild (554–567), coincided with the reign of Justinian and the temporary revival of the Eastern empire. Athanagild called on the imperial officers to help him against Agila, and paid for their assistance by the surrender of the province of Baetica. On his death there was an obscure interregnum of five months, which ended by the election of Liuva (567–572), the governor of Narbonne, the surviving remnant of the Visigoth power to the north of the Pyrenees. Liuva did not come to Spain, but associated his brother Leovigild (567–586) with him. The reigns of Leovigild and of his son Reccared are the greatest in the list of the Visigoth kingdom in Spain. The father was the first Visigothic king who wore the crown, and it would appear that he threw off all pretence of allegiance to the empire. The series of the Visigothic gold coins begins with him, and it is to be noted that while the earliest are struck in the name of the emperor Justinian, the imperial superscription disappears in the later. Leovigild drove the imperial officers from Seville and Cordova, though they still retained control of the coast.

The reign of Reccared (586–601) is famous in Spanish history for the establishment of Catholicism as the religion of the State. He made the change at the Third Council of Toledo. If Reccared hoped to secure the perpetuance of his dynasty he was mistaken. His son Liuva II. (601–603) was murdered by an Arian reaction headed by Witteric (603–610). The Catholics regained power by his overthrow, but they could not give stability to the State. A succession of obscure "priests' kings," who are but names, followed: Gunthemar (610–612), Sisebut (612–620), Reccared II. (620–621), Swintilla, associated with his son Reccimer (621–631), Sisinand (631–636), Chintila (636–640), Tulga (640–641), Chindaswinth (641–652), Recceswinth (649–672). The growing weakness of the Merovingians saved them from serious attack, though not from occasional invasion on the north. The prostration of the empire in the East by Avar and Persian invasions enabled them to drive the imperial officers from the coast towns. But the kingdom was growing internally weaker. Wamba (672–680) is credited with an attempt to reform the State, but he was tonsured while unconscious from illness or poison, and disappeared into a religious house. His successors again are but names, Euric (680–687) and Egica (687–701). Witiza (697–710) has more substance. With Roderic, whose "tumultuous" election was the work of Witiza's enemies, the line of the Visigoth kings is considered to have ended.

The Mohammedan Conquest.—During the reign of Witiza the Muslim masters of northern Africa had pressed the town of Ceuta, the last remnant of the Byzantine possessions, very closely. It seems to be certain that Julian, the imperial count or governor of Ceuta, acting in concert with the family and faction of Witiza, who sought his help against Roderic, provided vessels to transport the Berber Tarik (Tāriq) across the straits. Tarik, the general of the caliph's governor in northern Africa, Mūsā b. Nosair, came with a small force, but with the certainty of finding allies, and on being joined by another detachment of Berbers marched inland. On July 19, 711, he met Roderic near the Lago de la Janda between Medina Sidonia and Vejer de la Frontera. He had perhaps already been joined by Spanish allies. It is at least certain that in the battle the enemies of Roderic passed over to the invader. The Visigoth king was routed and disappears from authentic history. There is some probability that he did not perish in the battle, but escaped to fall two years later, at Seguyjuela near Salamanca, in action with Merwan the son of Mūsā. Before the end of 711 Tarik had advanced as far north as Alcalá. Cordova fell to a detachment of his army. In 712 Mūsā joined his lieutenant, and the conquest of the south was completed. Mérida was the only town which offered an honourable resistance. During 713 and 714 the north was subdued to the foot of the mountains, and when Mūsā and Tarik were recalled to Damascus by the caliph the progress of the Muslims was not delayed. In 718 they crossed the Pyrenees, and continued their invasions of Gaul till they met the solid power of the Austrasian Franks at Poitiers 732 (*see* CHARLES MARTEL and CALIPHATE). The great landowners south of the Pyrenees, to whom patriotism was unknown and whose religious faith was tepid, were as ready to pay tribute to the caliph as to render service to one of their own body who had become king by violence or intrigue. On the part of the Arabs, who, though a small minority of the invaders, were the ruling element, there was a marked absence of proselytizing zeal. They treated the occupation of Spain as a financial speculation more than as a war for the faith. The Spanish Roman and Visigoth, accustomed as he was to compound with one master after another, saw nothing dishonourable in making such an arrangement. In Murcia the duke whom the Arabs knew as Tadmir became a tributary prince, and his family retained the principality for generations. The family of Witiza obtained possession of an immense stretch of the land of the State in Andalusia on condition of paying tribute. One of them, by name Ardabast, was deprived of his holding at a later date on the ground that he held more land than could be safely left in the hands of a Christian. Everywhere landowners made the bargain, and the monasteries and the cities followed their example. Many professed themselves converts to Mohammedanism. In the north one great Visigoth family not only accepted Islam, but founded a dynasty, with its capital at Saragossa, which played a stirring part in the 8th and 9th centuries, the Beni-Casi, or Beni-Lope. To the mass of the population the conquest was, for the present, a pure gain. The Jews, escaped from brutal persecution, were the eager allies of the Arabs. The serfs acquired personal freedom and relief from the Roman fiscal system. Add to this that a slave who professed Islam could secure his freedom, at least from slavery to a Christian master, that Arianism had not been quite rooted out, that the country districts were still largely pagan, and it will not appear wonderful that within a generation Mohammedan Spain was full of renegades. The Arabs at first were content to take a fifth of the land to constitute the public domain, or *khoms*, out of which fiefs held on military tenure were provided for the chiefs of the conquering army.

The invaders were a coalition of Arabs, Syrians and Berbers. The Arabs, incurably anarchical, with no political idea except the tribal one, looked down on the Syrian; they thought the Berber a lout and a plebeian, they scorned the renegade, and called him a slave and son of a slave. They fought out the old tribal rivalries of Arabia on the banks of the Guadalquivir and on the Vega of Granada. They planted the Berber down on the bleak, ill-watered and wind-swept central plateau. He revolted, and they strove to subdue him by the sword. He deserted his poor share of the conquered land, and in many cases returned to Africa. The conflict for the caliphate (*q.v.*) between Omayyad and Abbasid removed all shadow of control by the head of the Mohammedan world, and Spain was given up to mere anarchy. The treaties made with the Christians were soon violated, and it seemed as if Islam would destroy itself. From that fate it was preserved by the arrival in Spain of Abdurrahman (Abdarrahman b. Moawiya) the Omayyad (758), one of the few princes of his house who escaped massacre at the hands of the Abbasides. With the help of his clansmen among the Arabs, and to a large extent of the renegades who counted as his clients, by craft, by the sword, by keeping down the fanatical Berber element, and by forming a mercenary army of African negroes, and after 30 years of blood and battle, Abdurrahman founded the independent amirate, which in the 10th century became the caliphate of Cordova. The real basis of its power was the slave army of negroes, or of Christian slaves, largely Slavonians sold by their German captors to the Jew slave traders of Verdun, and by them brought to Spain. These janissaries at first gave them victory, and then destroyed them.

Christian States of the North.—The Christian enemies of the Mohammedans were for long weak and no less anarchical than themselves, but they were never altogether wanting, and they had, what the Arab and Berber had not, a tradition of law and a capacity for forming an organized polity and a State. In the centre were the Basques, dwelling on both sides of the Pyrenees, who kept against the Mohammedan the independence they had vindicated

against the Visigoth On the east were the roots of the kingdom of Navarre, of Sobrarbe and Aragon In the earliest times their most pressing foe was not the Arab or Berber so much as the Carolingian It was at their hands that Charlemagne (*q.v.*), while returning from his expedition to Saragossa, suffered that disaster to his rearguard at Roncesvalles which is more famous in poetry than important in history With the aid of the Spanish Muslim Beni-Casi the Basques drove off the counts and wardens of the marches of the Carolingians On the eastern extremity of the Pyrenees the Franks found no native free population Here, mainly under the leadership of Louis the Pious, they formed the Marca Hispanica, where Frankish counts and wardens of the marches gradually gained ground. By the reign of Charles the Fat a principality had been founded Wilfred the Hairy—the *Comes Vellosus*, so called because his countship was poor and covered with scrub wood—became the founder of the countship of Barcelona

The greatest destiny was reserved for the Christian remnant which stood out to the west of the Basques, in the mountains of Asturias Pelayo, whom they chose for king, and his victory of Covadonga, are legendary and obscure. It is with the warning that the dates can only be given as probably correct that the three first Christian kings can be said to have reigned from 718 to 757 Pelayo (718–737), his brother Favila (737–739)—of whom we only know that he is said to have been killed by a bear while hunting—and Alphonso I, the Catholic (739–757), stand as little more than names While the Muslim invasion of Gaul was still going on, Manuza, the chief of the Berbers settled in north-western Spain, had revolted against the caliph's lieutenants In 740 came the great general revolt of the Berbers In 750 plague, following on drought and famine, swept away thousands of conquered and conquerors alike Amid the general desolation Alphonso I, duke of Cantabria and son-in-law of Pelayo, constituted the kingdom which the Arabs called Galicia It answered closely to the old Roman province of the same name—extending from the Bay of Biscay to the line of the Duero, from the ocean to the foot of the mountains of Navarre Alphonso swept all through that region, already more than half depopulated, slaying the lingering remnants of the Berbers, and carrying back the surviving Christians to the north Behind that shield of waste the Christian kingdom developed, from the death of Alphonso I. to the reign of Ramiro II (931–950) it was subject to no serious attack, though raids on the frontier never ceased Norse pirates appeared on the coast in the 9th century, but made no permanent settlements As the population grew, it pushed down to the plain of Leon and Castile The advance is marked by the removals of the capital forward from Cangas de Oña to Oviedo, from Oviedo to Leon, and by the settlement of adventurous frontier men in the ancient Bardulia, which from their "peels," and towers of strength, gained the name of Castilla—the castles Burgos became its centre The Montaña (hill country) of Burgos, and in particular the district called the Alfoz of Lara, was the cradle of the heroes of the Castilian share in the reconquest As the Marca Hispanica on the east became the county of Barcelona, so the chiefs of Bardulia became the counts of Castile, then the count of Castile, the rival of the king at Leon, and in time the king of Castile, and head of Christian Spain

There is much in the internal history of that kingdom which stands apart from the general development of western Europe, from which it was shut out In all the long period from Pelayo to Ramiro II only one event occurred which had much tendency to bring the Christians of the north-west into close relations with their neighbours of the same faith north of the Pyrenees This was the discovery of the body of St James the Apostle in the reign of Alphonso II the Chaste (789–842). The shrine at Santiago in Galicia attracted pilgrims, who brought trade The chief who had to "people" a new and exposed township had to tempt men by freedom and secure rights to follow his banner. The influences which by the 13th century had abolished serfdom in western Spain were all at work before the reign of Ramiro II In spite of revolts and of fratricidal struggles a State was formed. To the east of it, the Navarrese, having rid themselves of the Carolingian counts and marchers, had made a kingdom in their mountains, and beyond them the little free territories of the central Pyrenees were advancing, in subordination to the Navarrese king at Pamplona The Arab called them the Christians of Al Frank, and distinguished them from the Galicians

The Mohammedan Amirate.—The 10th century and the first years of the 11th saw a great set-back of the Christian revival Dissensions among themselves coincided with an energetic rally of the Muslim power. From the foundation of the amirate by Abdurrahman I (758–790) to the beginning of the reign of Abdurrahman III (912–961) Mohammedan Spain had shared the usual fortunes of an oriental monarchy A strong amir, such as Abdurrahman I or his grandson Hakam I (796–822), could enforce obedience by arms, or by murder On the upper frontier, which is now Aragon, the "Visigoth" Beni-Casi ruled, doing homage and paying tribute intermittently, supported by a loyal population of native Mohammedans, whose Christian or nominally Christian fathers had been their followers before the conquest The "Moors," so called, who afterwards filled the kingdom of Aragon, were of native blood Toledo, relying on the immense military strength of its position, was more often in rebellion than in subordination The massacre which Hakam I effected by a lavish use of fraud cowed it only for a time Abdurrahman III found it independent again when he came to the throne, and had to besiege it for two years before it yielded The renegades grew in numbers, and in faith Under the influence of orthodox Berber teachers their fanaticism was turned against the amir himself Hakam, a winebibber much suspected of heterodoxy, had to expel thousands from his capital Part went to people the town of Fez newly founded in Morocco by the Idrisites; part wandered eastward to found a Mohammedan State in Crete Under the stimulus of Berber fanaticism the toleration first shown to the Christians was turned to persecution A counter fanaticism was aroused in them, and for years the "Martyrs of Cordova" continued to force the often reluctant cadis to behead them, by blaspheming the Prophet Under Abdurrahman II (822–852), who spent his life listening to a favourite and highly accomplished Persian tenor and in the company of dancing girls, and under Mohammed I (852–886), the niggardly Mondhir (886–888), whose time was short, and Abdalla (888–912), who was feeble, the amirate was torn to fragments

From this state of anarchy the amirate was saved by Abdurrahman III (912–961), the Akbar of his race He came to the throne when half a century of war and murder had produced exhaustion The country was swarming with brigands, and the communications were so dangerous that seven years had been known to pass during which no caravan travelled from Cordova to Saragossa Abdurrahman III, an oriental ruler of the great type, industrious, resolute, capable of justice, magnificent, and free-handed without profusion, was eminently qualified to give all that his people wanted The splendour of his reign is a commonplace He restored order even in the Sierra de Ronda, and then he took the field against the Christians.

Hakam II (961–976), Abdurrahman's son, ascended the throne in mature years, and continued his father's policy A lover of books, he gave protection to writers and thinkers who were not strictly orthodox The anarchy which broke out in the north-west, the kingdom now called Leon, on the death of Ramiro II—whose sons fought among themselves—and the endless conflicts between Leon and Castile, rendered the only formidable Christian kingdom powerless. In Hakam's old age, one of his wives Sobh (the Daybreak), a Basque, bore him the first son born in his harem, who became Hishām II and in all his long life was nothing but a puppet. The administration of his chamberlain or *hajib*, Mohammed ben Abdallah, who took the royal name al-Mansur Billah ("the victorious through God") and is generally known as Mansur (*q.v.*), is counted among the glories of the caliphate of Cordova. It was the rule of a strong man who made, and kept under his own control, a janissary army of slaves from all nations Christian mercenaries from the north, Berbers and negroes from Africa With that host he made 50 invasions into the Christian territory, but he left his enemies in a position to regain all they had lost It mattered little that he desolated in 997 the shrine of

St. James at Santiago da Compostela, the monastery of Cardeña in Castile, took Leon, Pamplona and Barcelona, if at the end he left the roots of the Christian States firm in the soil, and to his son and successor as *hajib* only a mercenary army without loyalty. He died in 1002 undefeated, but racked by anxiety for the permanence of the prosperity of his house. His son Mozaffar kept the authority as *hajib,* always in the name of Hishām II., who was hidden away in a second palace suburb of Cordova, Zahira. But Mozaffar lasted for a short time, and then died, poisoned, as it was said, by his brother Abdurrahman, called Sanchol, the son of Mansur by a Christian lady. Abdurrahman Sanchol was vain and feather-headed. He extorted from the feeble caliph the title of successor, thereby deeply offending the princes of the Omayyad house and the populace of Cordova. He lost his hold on his slaves and mercenaries, whose chiefs had begun to think it would be more to their interest to divide the country among themselves. A palace revolution, headed by Mohammed, of the Omayyad family, who called himself Al Mahdi Billah (guided by God), and a street riot, upset the power of the *hajib* at Cordova while he was absent on a raid against Castile. His soldiers deserted him, and he was speedily slaughtered. Then in the twinkling of an eye the whole edifice went into ruin. The end of Hishām II. is unknown, and the other princes perished in a frantic scramble for the throne in which they were the puppets of military adventurers. A score of shifting principalities, each ready to help the Christians to destroy the others, took the place of the caliphate.

Development of the Christian Kingdoms.—The fundamental difference between the Muslim, who know only the despot and the Koran, and a Christian people who have the Church, a body of law and a Latin speech, was well seen in the contrast between the end of the greatness of Mansur, and the end of the weakness of his Christian contemporaries. The first left no trace. The second attained, after much fratricidal strife, to the foundation of a kingdom and of institutions. The interval between the death of Ramiro II. in 950 and the establishment of the kingdom of Castile by Fernando I. in 1037 is on the surface as anarchical as the Mohammedan confusion of any time. The personages are not anywise heroic, even when like Alphonso V. (999–1027) they were loyal to their duty. Sancho the Fat, and Bermudo II. the Gouty, with their shameless feuds in the presence of the common enemy, and their appeals to the caliph, were miserable enough. But the emancipation of the serfs made progress. Charters began to be given to the towns, and a class of burghers, endowed with rights and armed to defend them, was formed; while the council of the magnates was beginning to develop into a *cortes.* The council over which Alphonso V. of Leon and his wife Geloria (*i.e.,* Elvira) presided in 1020, conferred the great model charter of Leon, and passed laws for the whole kingdom. The monarchy became thoroughly hereditary, and one main source of anarchy was closed. By the beginning of the 11th century the leading place among the Christian kings had been taken by Sancho El Mayor (the Great) of Navarre. He was married to a sister of Garcia, the last count of Castile. Garcia was murdered by the sons of Count Vela of Alava whom he had despoiled, and Sancho took possession of Castile, giving the government of it to his son Fernando (Ferdinand I.), with the title of king, and taking the name of "king of the Spains" for himself. Fernando was married to a daughter of Alphonso V. of Leon. Her brother Bermudo, the last of his line, could not live in peace with the new king, and lost his life in the battle of Tamaron, in a war which he had himself provoked. Fernando now united all the north-west of Spain into the kingdom of Castile and Leon with Galicia. Navarre was left by Sancho to another son, Garcia, while the small Christian States of the central Pyrenees, Aragon and Sobrarbe with the Ribagorza went to his other sons, Ramiro Sanchez and Gonzalo. Fernando, as the elder, called himself emperor, and asserted a general superiority over his brothers. When he had united his kingdom, he took the field against the Mohammedans; and the period of the great reconquest began.

Beginning of the Christian Reconquest.—The Christians advanced to the banks of the Tagus in the south, and into Valencia on the south-east. They began to close round Toledo, the shield of Andalusia. The feeble Andalusian princes were terrified into paying tribute, and Fernando reached the very gates of Seville without finding an enemy to meet him in the field. His death in 1065 brought about a pause for a time. He left his three kingdoms to his three sons Sancho, Alphonso and Garcia. Alphonso, to whom Leon had fallen as his share, remained master after the murder of Sancho at Zamora, which he was endeavouring to take from his sister, and the imprisonment of Garcia of Galicia. The reign of Alphonso VI., which lasted till 1109, is one of the fullest in the annals of Spain. His marriage with Constance, daughter of Robert, duke of Burgundy, brought a powerful foreign influence into play in Castile. Constance favoured the monks of Cluny, and obtained her husband's favour for them. Under their leadership measures were taken to reform the Church. Castile ceased to be an isolated kingdom, and became an advance guard of Europe in not the least vital part of the crusades. Alphonso, who during his exile owed some good services to the Mohammedan king of Toledo, spared that city while his friend lived. In 1082 he swept all through the valley of the Guadalquivir to Tarifa, where he rode his horse into the sea and claimed possession of the "last land in Spain." In 1086, his friend being dead, he made himself master of Toledo. The fall of the city resounded throughout Islam, and the Mohammedan princes of Andalusia began to look to Africa, where Yusuf ben Techufin was ruling the newly founded empire of the Almorávides. Al-Motamid, amir of Seville, a brilliant cavalier, an accomplished Arab poet, and one of the most amiably spendthrift of princes, thought it better to lead camels in Africa than to tend pigs in Castile. Yusuf came, and in 1086 inflicted a terrible defeat on Alphonso VI. at Zalaca near Badajoz. The immediate results of the stricken field were, however, but small. Yusuf was called back to Africa, and in his absence the Christians resumed the advance. When he returned he was chiefly employed in suppressing the Mohammedan princes. Alphonso was compelled to withdraw a garrison he had placed in Murcia, and Valencia was, by his decision, given up by the widow of the Cid (*q.v.*). But he kept his hold on Toledo, and though his last days were darkened by the death of his only son in the lost battle of Ucles (1108), he died in 1109 with the security that his work would last.

The Almorávides.—The Almorávides, who were Berbers and were largely mingled with pure negroes, added to corruption a dull bigotry and a hatred of thought and knowledge from which the Arab, anarchical and politically incapable as he was, was free. In Aragon the successors of Ramiro Sanchez had begun to press close on Saragossa when the Almorávide invasion took place. The battle of Zalaca gave pause to the Aragonese, as it did for a short space to the Castilians. The interval of advance in the reconquest would have been shorter than it was but for the results of a most unfortunate attempt on the part of Alphonso VI. to unite the Crowns of Aragon and Castile by the marriage of Alphonso I. (1104–34) of Aragon with his daughter Urraca. Urraca (the name is a form of Maria) was dissolute and Alphonso was arbitrary. They came to open war, in which he claimed to be king of Castile by right of his marriage and his election by the nobles. The confusion was increased by the fact that Alphonso, Urraca's son by her first marriage with Raymond of Burgundy, was recognized as king in Galicia, was bred up there by the able bishop Diego Gelmirez, and took an active part in the feuds of his mother and stepfather. The death of Urraca in 1126 allowed her son to reunite the dominions of his grandfather. In the meantime his quarrels with Urraca had not deterred Alphonso, who is surnamed the Battler in Aragonese history, from taking Saragossa in 1118, and from defeating the Almorávides at the decisive battle of Cutanda in 1120. In 1125 he carried out a great raid through Mohammedan Spain, camping in its midst for months, and returning with many thousands of the Christian *rayahs,* who, under the name of Mozárabes, had hitherto continued to live under Muslim rule. After his death his brother, Ramiro, having been first exclaustrated by the pope, married Agnes of Aquitaine, and on the birth of his daughter Petronilla affianced her to Ramon Berenguer (Raymond Berenger), count of Barcelona, and then retired to his

cell at Narbonne. This marriage united Aragon and Catalonia for ever, and marks a great step forward in the constitution of a national unity in Spain. Navarre, indeed, which had been united with Aragon since the fratricidal murder of its king Sancho in 1076, preferred to remain independent under a new ruler of its choice. It was henceforth a small State lying across the Pyrenees, dependent on France, and doomed inevitably to be partitioned between its great neighbours to north and south

Alphonso VII, the son of Urraca, was, during the 20 years between his mother's death and his own in 1157, the dominating sovereign of Spain In 1135 he was crowned at Leon, in the presence of the new king of Navarre, of the counts of Barcelona and Toulouse, and of other princes, Christian and Mohammedan, "emperor in Spain, and king of the men of the two religions" He took Cordova and conquered as far as Almeria, but left vassal Muslim princes in possession At his death Sancho, his eldest son, succeeded him in Castile and Fernando in Leon Portugal had already become a semi-independent State

The Almohádes.—Alphonso VIII married Leonora, daughter of Henry II. of England, who, as duke of Aquitaine, by right of his marriage with the duchess Eleanor, had a strong direct interest in Spanish politics. In Andalusia the downfall of the Almorávides had opened the way to the Almohádes, or followers of the Mahdi, an even more bigoted religious sect Alphonso had conquered Cuenca, in the hill country between Castile and Valencia, in 1177, with the help of the king of Aragon, also an Alphonso, the son of Petronilla and of Ramon Berenguer of Barcelona, and rewarded his ally by resigning all claim to feudal superiority over Aragon At a later period the two kingdoms defined their respective spheres of influence by a treaty Aragon was left free to conquer the Balearic islands and Valencia, while Murcia and Andalusia were to fall to Castile The Almohádes took the field against Alphonso in force, and as his fellow Christian sovereigns failed him in the hour of need, he was defeated at Alarcos (1195) To this age belongs the formation of the great monastic military orders of Calatrava, Santiago and Alcántara They supplied the Crown with a strong force of well-disciplined and well-appointed cavalry To tighten the bond with Leon, Alphonso of Castile married his daughter Berengaria to its king Alphonso (1188–1230), the son of his uncle Fernando The marriage was dissolved by the pope as being within the prohibited degrees, but the son born of it was recognized as legitimate Berengaria, a woman of very noble character and eminent ability, deserved a better husband than her cousin of Leon, who was nicknamed El Baboso—the Slobberer—and who appears to have been epileptic In 1212 the king of Castile reaped the reward of long years of patience The Almohádes threatened an invasion in force, and he organized a crusade against them Aragon was represented by its king Peter II, Navarre by its king Sancho, and Portugal by a strong contingent of Templars and other knights At Las Navas de Tolosa, just south of the Sierra Morena, the Almohades received (1212) the final overthrow which laid Mohammedan Spain at the feet of the Christians. Alphonso died in 1214 His son Enrique (Henry) was killed by the fall of a tile three years later; and Berengaria, to whom the Crown came, sent to Leon for her son Fernando, and abdicated in his favour

Reconquest of Spain Except Granada.—Fernando (Ferdinand III.) continued the advance into Andalusia. The Almohádes were in swifter decline than the Almorávides. One of them, al-Mamun, even sought Fernando's help to regain his throne in Morocco, and ceded a suburb of the city to his Christian allies. In 1230 the death of Alphonso of Leon opened the way to a final union of the Crowns of Castile and Leon The work of the reconquest was now completed with swift steps. In 1236 Cordova was conquered, and Seville fell in 1248 with the help of a fleet from the Basque coast and of the Moorish king of Granada, who was Fernando's vassal, paying tribute and attending *cortes* when summoned. Fernando died in May 1252. The Aragonese share of the reconquest was completed by James the Conqueror (1213–76). He conquered the Balearic islands in 1229 and Valencia in 1238. Mohammedan Spain was reduced to Granada and a line of ports round to Cadiz.

The close of the period of the great reconquest, five centuries of struggle, left Spain divided between two States of different character On the west of the Iberian range and south of the Guadarrama was the kingdom called, for short, Castile and Leon In fact its sovereign was also king of Galicia, Asturias, Extremadura, Jaen, Cordova and Seville

On the eastern slope of the Iberian hills and the great central table-land was the kingdom called, again for short, Aragon Its king was also a ruler of many titles—king in Aragon, in Valencia and the Balearic Isles (with one interval of separation), count of Barcelona, and in Provence. Marriage and inheritance had given him territorial rights in the south-east of France Thus he came in contact with the crusaders of Simon de Montfort and the expansion of the French monarchy Another marriage, that of Peter, the son and successor of James the Conqueror, with Costanza, the daughter of Manfred of Beneventum, gave him claims on the Neapolitan and Sicilian inheritance of the Hohenstaufen From the date of the Sicilian Vespers (1283) Aragon is found mixed in the politics of Italy The commercial activity of Barcelona brought it into collision with Genoa and alliance with Venice The curious double position of the king of Aragon is fully illustrated by the career of that king Peter who was the father of James the Conqueror He fought as a crusader at Las Navas de Tolosa, he went to Rome to be crowned, and did voluntary homage to the pope Yet his interests as a prince of southern France compelled him to draw the sword in defence of the Albigenses, and, orthodox as he was in creed, he fell fighting for them at Muret in 1213.

The distinction of classes was far sharper in Aragon than in non-feudal Castile and Leon Predial slavery, which had disappeared in Castile and Leon in the 13th century, existed unmodified in Aragon, and in its worst form, down to the Bourbon dynasty Freedom was confined to the citizens of the towns which had charters—called in Aragon the Universidades—the nobles, the gentry and the Church. The Catalans attained emancipation from feudal subjection by a succession of savage peasant revolts in the 15th and 16th centuries. In Valencia emancipation was finally brought by a measure which in itself was cruel—the expulsion of the Moriscos in the 17th century The landlords were compelled to replace them by free tenants The prevalence of predial slavery in Aragon and Valencia can be largely explained by the number of Mudéjares, that is Mohammedans living under Christian rule, and of Moriscos—converted Mohammedans

Christianization of Spain.—The Jews, who had suffered cruelly from the brutal fanaticism of the Almohádes, had done a great deal to forward the conquest of Andalusia They were repaid by the confidence of the king, and the period which includes the reign of Fernando and lasts till the end of the 14th century was the golden age of their history in Spain. In 1391 the preaching of a priest of Seville, Fernando Martinez, led to the first general massacre of the Jews, who were envied for their prosperity and hated because they were the king's tax collectors But the history of the persecution and expulsion of the Jews is the same everywhere except in date The story of the Mudéjares and Moriscos is peculiarly Spanish Forced conversion prepared the way for expulsion, which came in the reign of Philip III. (1598–1621) In the majority of cases the conversion had occurred so long ago that the memory of the time when they were Mohammedans was lost, and multitudes of the children of Mudéjares remained. The Mozárabes again—the Christians who had always lived under Mohammedan rule—were an element of importance in mediaeval Spain. They had learnt to write in Arabic, and used Arabic letters even when writing Latin, or the corrupt dialect of Latin which they spoke The Mozárabes were treated under the kings of the reconquest as separate bodies with their own judges and law, which they had been allowed to keep by the Muslim rulers. That code was the *forum judicum* of the Visigoths, the *fuero juzgo*, as it was called in the "romance" of later times and in Castilian. The Mozárabes brought in the large Arabic element, which is one of the features of the Castilian language.

Problem of the Unification of Spain.—The work of political unification was essentially more difficult than the christianiza-

tion of Spain. The Galician who spoke, and still speaks, a language of his own, was profoundly separated from the Andalusian. The Basque, who till much later times practically included the Navarrese, was a man of another nationality and another speech from the Castilian. And what is true of Castile and Leon applies equally to Aragon. Aragonese, Catalans and Valencians were as different as Galicians, Basques, Castilians and Andalusians. Aragon spoke a dialect of Castilian. Catalonia and Valencia, together with the Balearic islands, spoke, and speak, dialects of the southern French, the so-called Limosé, though it was not the language of the Limousin. High mountain barriers and deep river courses had separated the Spaniards locally. They were more subtly and incurably separated by traditional and legal status. Under the Crown of Castile all the territory was either *abadengo, realengo, salariego, behetria,* or it belonged to some town, big or little, which had its *carta pueblo* or town charter, its own *fuero* (forum) or law. *Abadengo* was land of the Church, *realengo* domain of the Crown, *salariego* land of the nobles. *Behetria* is less easy to translate. The word is the romance form of *benefactoria.* Behetrias, called "plebian lordships," were districts and townships of peasants who were bound to have a lord, and to make him payments in money or in kind, but who had a varying freedom of choice in electing their lord. Some were described as "from sea to sea, and seven times a day," that is to say they could take him anywhere in the king's dominions from the Bay of Biscay to the Straits of Gibraltar, and change him as often as they pleased. Others were *de linage,* that is to say, bound to take their lord from certain lineages. Their origin must probably be sought in the action of communities of Mozárabes, Christians living under Muslim rule as *rayahs,* who put themselves under Christian chiefs of the early days of the reconquest for the *benefice* of their protection. They were mainly in old Castile. By the end of the middle ages they had disappeared. The chartered towns, in Spain east and west, were practically republics living under their own *carta pueblo* with their own *fuero* or law. All charters were not granted by the king. Many of them were given by nobles or ecclesiastics, but required the confirmation of the king. And in this country, where all was local law usage and privilege, where uniformity was unknown, all charters were not held by towns. In many cases the serfs in the course of their struggle for freedom extorted charters and *fueros.* The greater chartered towns had their surrounding *comarcas,* answering to the "county" of an Italian city, over which they exercised jurisdiction. In time the villages dependent on a chartered city, as they grew to be towns themselves, fought for, and in many cases won, emancipation, which they then sought to have confirmed by the king and proceeded to symbolize by setting up their own gallows in the market-place. The Church had won exemption from the payment of taxes by no general law, but by particular privilege to this or that chapter, bishopric or monastery. The nobles claimed, and were allowed, exemption from taxation. Church and nobles alike were for ever extending their borders by purchase, or trying to do so by force. They conferred their exemptions on the land they acquired, thus throwing the burden of taxation on the towns and the non-nobles with increasing weight. But there was in reality no sharp division except in the smaller and feudal portion—called Aragon for convenience—and save as between Christian and non-Christian, noble and non-noble. The necessities of the reconquest made it obligatory that all the dwellers on the frontier should be garrison. Hence they were not only encouraged but required to possess arms. Those of them who could provide themselves with a charger, a mail shirt, a spear and sword were ranked as *milites*—and the *miles* was a *caballero.*

The Kings of Castile.—Alphonso X. of Castile (1252–84) was a writer, and a man of keen intelligent interest in science and law. As a ruler he was at once weak, unstable and obstinate. He wasted much time and great sums of money in endeavouring to secure his election as emperor—not in Spain, but in the Holy Roman empire. He did indeed add the town of Cadiz to his possessions with the help of his vassal, the Moorish king of Granada, but his reign is filled with quarrels between himself and his nobles. He ended his life in a war with his son Sancho, who claimed the succession in preference to the children of his elder brother, Fernando de la Cerda, in virtue of a doctrine that the younger son, being nearer to the father than the grandson, had a right to succeed in preference to the children of an elder brother who had died before the succession was open. Alphonso, after first accepting Sancho's claim, repudiated it, and made a will by which he not only left the Crown of Castile to the eldest son of Fernando de la Cerda, but cut vassal kingdoms out of the southern parts of Spain for Sancho's younger brothers. The reign of Sancho IV., surnamed El Bravo, or the Fierce (1284–96), was one constant struggle with the very nobles who had helped him against his father, with his younger brothers, and with the sons of Fernando de la Cerda. Murder and massacre were his familiar methods. He was succeeded by his infant son Fernando (Ferdinand IV.) whose long minority was an anarchy, tempered by the courage and the tact of his mother, Maria de Molina. Fernando, ungrateful to his mother and incapable as a king, died in 1312, leaving a son of less than a year old, Alphonso XI. (1312–50). After another minority of confusion, Alphonso, surnamed "of the Rio Salado," from the great victory he won over an invading host from Africa, ruled with energy and real political capacity. He did something to found the judicial and administrative unity of the country. His death at the age of 38, during the great plague, and while he was besieging Gibraltar, was a misfortune to Spain.

His successor, Peter, called the Cruel (1350–68) was destined to show the Castilians exactly what the constant use by "the prince" of the reserved rights of the sovereign authority could be made to mean, when they were exercised by a passionate man maddened by suspicion of all about him. Administering the civil side of his Government through Jewish tax-gatherers and farmers of the taxes, and surrounded by the Mudéjar guard, who were the executors of his justice, his path is marked by one long succession of murders. With all his appearance of energy, he shrank from action at the critical moment of his wars out of utter want of trust in all about him. His expulsion by his brother, Henry of Trastamara, the eldest son of Leonora de Guzman, his restoration by the Black Prince (*q.v.*), his treachery to him, and his final defeat and murder at Montiel, are famous episodes. Henry of Trastamara, the beginner of the "new kings" (1368–79), reigned by election. In his reign and those of his immediate successors the *cortes* flourished, although it failed to establish checks on the absolute power of the king. Henry was on the whole a successful ruler. He forced his neighbours of Portugal to make peace, his fleet defeated an English squadron off Rochelle, and he restored internal order. The civic *hermandades,* or brotherhoods, enforced respect from the nobles. John I. (1379–90), Henry's son and successor, had to contend with John of Gaunt, son of Edward III. of England, who had married the eldest daughter of Peter the Cruel, and claimed the Crown of Castile in her name. John averted the danger by arranging a marriage between his son Henry and Constance, the eldest daughter of John of Gaunt, an alliance which united the two equally illegitimate lines representing Alphonso XI.; and so closed the dispute as to the succession. He was less fortunate in his efforts to vindicate the rights of his wife Beatriz to the throne of Portugal. The defeat of the Castilians at the battle of Aljubarrota (1385) compelled the king to renounce his pretensions. The minority of his son, Henry III. (1390–1406) was long, and his effective reign short, but in the brief space allowed him the king, a weakly man surnamed El Doliente (the sufferer) did something to establish order. He recovered all the immense grants of Crown lands and rents, impounded by the nobles during his minority. The first years of the minority of his infant son, John II. (1406–54), were by a rare exception peaceful. The young king's uncle Ferdinand acted as regent. Ferdinand was able and honest. His succession to the throne of Aragon is an event of capital importance.

The Kings of Aragon.—The kings of Aragon from the death of James the Conqueror in 1276 to the death of Martin I. in 1410 were so largely concerned in the struggle with the Angevin Party in Naples and Sicily, that their history belongs rather to Italy than to their Peninsular kingdom. They were six in number: Peter III. (1276–85), Alphonso III. (1285–91), James II. (1291–1327), Alphonso IV. (1327–36), Peter IV. (1336–87), John I.

(1387–95), and Martin I. (1395–1410). Their double task was to reunite the Balearic islands and Roussillon, which James the Conqueror had left by will to a younger son, to the Crown of Aragon, and to reduce their turbulent barons, in Aragon, Catalonia and Valencia alike, to the position of obedient subjects In both tasks Peter IV. ultimately achieved success. The barons of Aragon and Valencia had extorted from his weak father the charter known as the "Union," an instrument which was incompatible with the monarchical or any other form of government. The object of the life of Peter IV. was to force the barons to surrender their charter. After years of struggle and preliminary failures, Peter IV. defeated the "Union" utterly at the decisive battle of Epila (1348). He was a typical king of the 15th century, immeasurably false, and unspeakably ferocious, but he was not a mere bloodthirsty sultan like his enemy, Peter the Cruel of Castile When he won he took, indeed, a brutal vengeance on individuals, and he extorted the surrender of the charter and destroyed it with his dagger in the presence of the *cortes* at Saragossa He cut his hand in his eagerness, and declared that the blood of a king was well shed in securing the destruction of such an instrument—whence his popular nickname of Peter of the Dagger (*del Punyalet*). But his use of the victory was statesmanlike He fully confirmed the right of the nobles to trial by law and security against arbitrary punishment, he left the franchises of the city untouched, and respected the independence of the *justicia*. The result of his victory was to give Aragon and his other dominions a measure of internal peace unknown in Castile. The reigns of his sons and successors, John and Martin, were insignificant and tranquil The death of Martin without children in 1410 left the succession open The *cortes* was able to administer in peace, and the question of the succession was debated as if it had been in a suit between private persons. The judges finally decided in favour of Ferdinand, on the ground that his mother, Eleanor, was the daughter of Peter IV, and that though a woman could not reign as a "proprietary queen" in Aragon, she could convey the right to her husband or transmit it to her son

The years 1412–79 marked a growing approximation between the two States whose interests touched one another so closely In Castile John II. (1406–54), a man of amiable but indolent character and of literary tastes, was governed by his favourite, Álvaro de Luna, and harassed by his nobles At the end of his life he sacrificed his favourite at the instigation of his second wife Of his son, Henry IV. (1454–74) it is enough to say that he was called "the Impotent," and that there is every reason to believe that he deserved the description in all the senses of the word His reign was an inferior copy of his father's As the legitimacy of his alleged daughter Juana was disputed, his sister Isabella claimed the succession, and married her cousin, Ferdinand of Aragon, son of John I, in 1469 in defiance of her brother In Aragon, Ferdinand I "of Antequera" (1412–16) was succeeded by Alphonso V. (1416–58) the Magnanimous, whose brilliant life belongs to Italy In Aragon he was represented by his brother John, who administered as lieutenant-general, and who reigned in his own right (1458–79) when Alphonso V. died without legitimate heirs, leaving Naples by will to a bastard son. John I, a man of indomitable energy and considerable capacity, spent most of his life in endeavouring to enforce his claims to the kingdom of Navarre as the husband and heir of its queen Blanche His conflict with his son by his first marriage, Charles, prince of Viana, was settled in his favour by the death of the prince. A national revolt was suppressed in Catalonia At the age of over 80, the blind old king transmitted his kingdom to Ferdinand, his son by his second marriage, with Juana Enriquez, of the family of the hereditary admirals of Castile Navarre went to a daughter, and Roussillon was somewhat fraudulently retained by Louis XI. as security for a debt. Ferdinand conquered the Spanish half of Navarre later, and recovered Roussillon from Charles VIII, the successor of Louis XI.

With the death of John I. of Aragon in 1479 the history of Spain enters on an entirely new period Hitherto it has been the story of a national development. The process did not cease, but, during the reign of Isabella the Catholic (1474–1504) until the death of her husband Ferdinand in 1516, was carried, not to completion, but to the stopping place at which it was destined to rest for two centuries The voyage of Columbus in 1492, and the intervention of Ferdinand in the great conflict of France, the empire and the papacy for predominance in Italy, had, simultaneously, the effect of opening to her the world of conquest and adventure in America, and of committing her to incessant wars in the Italian peninsula. The death of John, the only son of Ferdinand and Isabella, the worst misfortune which ever happened to Spain, opened the succession to all the crowns and coronets worn by the Catholic sovereigns to Charles of Habsburg—the emperor Charles V. From that day Spain became a part—the leader, then the paymaster, then the dupe—of the international monarchical confederation called "the illustrious House of Austria" The Spaniard became the swordsman and executioner of the counter-Reformation, because the power of the House of Austria depended on the imposition of religious unity in Europe. The decision of Charles V, king of Spain and emperor, to leave the Netherlands to his son Philip II, committed the Spaniards to conflict on the sea with England, and to the insane attempt to secure a safe road for their armies across Europe from the shores of the Mediterranean to the North sea. Meanwhile the Spaniards were endeavouring to check the advance of the Turks in the Mediterranean, and to exclude all Europe from the waters of the New World

Ferdinand and Isabella.—Ferdinand and Isabella were proclaimed king and queen of Castile together, although the Crown was hers alone, and although she never consented to part with her sovereign authority. In the purely internal affairs of Castile it was always she who decided on questions of administration They immediately began the work of establishing order and obedience in their dominions The line of policy followed by the Catholic sovereigns was to keep the old forms, but draw the substance of power to themselves This course was followed with the *cortes* It continued to be summoned by the Catholic sovereigns and their successors of the Habsburg line, but it was needed only to grant money. The nobles and the clergy, who as exempt from taxation had no vote, became purely ornamental parts of the *cortes*. The representatives of the third estate were confined by the indifference of the Castilians to 18 towns, whose procurators were named by the councils either from among themselves in rotation, or from particular families. The Catholic sovereigns provided themselves with a revenue by the customary wholesale resumptions of grants made during the reigns of John II. and Henry IV, and by the suppression or reduction of the pensions they had granted with profusion. Encouragement of industry was not wanting; the State undertook to develop the herds of merino sheep, by issuing prohibitions against inclosures, which proved the ruin of agriculture, and gave premiums for large merchant ships, which ruined the owners of small vessels and reduced the merchant navy of Spain to a handful of galleons *Tasas,* fixed prices, were placed on everything. The weaver, the fuller, the armourer, the potter, the shoemaker were told exactly how to do their own work. All this did not bear its full fruit during the reign of the Catholic sovereigns, but by the end of the 16th century it had reduced Spain to a state of Byzantine regulation in which every kind of work had to be done under the eye and subject to the interference of a vast swarm of Government officials, all ill paid, and often not paid, all corrupt All this also did not bear its full fruit till later times, but by the 17th century it had made Spain one of the two "most beggarly nations in Europe"—the other being Portugal

The Spanish Inquisition.—The policy of the Catholic sovereigns towards the Church was of essentially the same character as their treatment of the nobles or the cities They aimed at using it as an instrument of government One of the first measures adopted by them in Castile, before the union with Aragon, was to stop the nomination of foreigners to Spanish benefices by the pope. But the most characteristic part of their ecclesiastical policy was the establishment of the Spanish Inquisition (*q v*) By the bull of Sixtus IV. of 1578 they obtained authority to appoint three inquisitors, whom they were empowered to remove or replace, and who were independent of, and superior to, the inquisi-

torial courts of the bishops. The Inquisition was at first established (in 1480) in the dominions of Castile only, but it was extended in 1486 to Catalonia and in 1487 to Aragon, in spite of strong protests. The first duties of the Inquisition were to deal with the converted Jews and Mohammedans, respectively known as Marranos and Moriscos. Professed Jews were expelled in 1492, and the Mohammedans or Mudéjares in 1502. Both were industrious classes, and the loss of their services was disastrous to Spain—the first of a long series of similar measures which culminated in the final expulsion of the Moriscos in 1610. The converted Jews and Mohammedans presented greater difficulties to the Inquisition. Many of the higher ecclesiastics and of the nobility were of Jewish, or partially Jewish, descent.

Conquest of Granada.—Between 1481 and 1492 the Catholic sovereigns completed the work of the reconquest by subjugating the one surviving Mohammedan State of Granada. Their task was materially facilitated by dissensions among the Moors. The surrender of Granada on Jan. 2, 1492, was partly secured by promises of toleration, which were soon violated. A revolt had to be suppressed in 1501. Having secured the unity of their territory in the peninsula, the Catholic sovereigns were free to begin the work of expansion. In 1492 Columbus (*q.v.*) sailed on his first voyage to the west. In 1493 Ferdinand secured the restoration of Roussillon from Charles VIII. of France by the fallacious treaty in which he undertook to remain neutral during the king's expedition to Italy. The voyage of Columbus had unforeseen consequences which led to diplomatic difficulties with Portugal, and the Treaty of Tordesillas in 1494, which defined the respective spheres of influence of the two Powers in the New World and in Asia. In 1497 Ferdinand, with the support of his wife, entered on those wars of Italy in which the Spanish regular soldiers first gained their reputation, and which made Spain for a time the dominant Power in the Italian peninsula (*see* CORDOBA, GONZALO F. DE). They endeavoured to strengthen themselves against France by marriages with the royal family of England (*see* CATHERINE OF ARAGON) and the Habsburgs. The marriage of Juana, called the Mad, with Philip of Habsburg, son of the emperor Maximilian (*q.v.*), brought a new dynasty to Spain. On the death of Queen Isabella in 1504 her son-in-law claimed the regency, and was supported by the Castilian nobles. His death in 1506 and the insanity of his widow left the Castilians no choice but to restore Ferdinand as regent. During the next ten years Ferdinand governed with the very able assistance of the archbishop of Toledo, Jimenez de Cisneros (*q.v.*). He annexed the southern part of Navarre, which was held by the representatives of his half-sister. The archbishop organized and directed the expedition which conquered Oran, Tripoli and other points on the African coast. Here beyond all doubt lay the proper field for the expansion of Spain. She was drawn from it on the death of Ferdinand in 1516. He was succeeded by his grandson Charles of Habsburg, and when Charles was elected to the empire in 1519 Spain was dragged into the wars and politics of Central Europe.

(A. E. Ho.; A. B.)

THE AUSTRIAN HOUSE

The Emperor Charles V.—Only the smaller part of the reign of Charles was spent in Spain. He came to it from Flanders, where he had received his education, unable to speak the Spanish language and surrounded by Flemish favourites. Furthermore, and this was the chief cause of his misunderstandings with the Spaniards, his mind was mainly preoccupied with the international policy of the house of Burgundy and the empire, a foreign policy which could arouse no interest and was not even understood in Spain. Charles knew nothing either of Spanish ideas or of the national tradition of the new States to which he had succeeded. To him and his favourites the new country was only a source of supply from which money was to be obtained in order to bribe the German electors.

European Policy of Charles V.—The conquest of Mexico by Hernan Cortes (*q.v.*) and of Peru by Francisco Pizarro (*q.v.*) belong to this reign. These conquests and the incessant wars into which Spain was drawn by the Aragonese claims in Italy, and its connection with the empire, gave to the nation a great European position and to the Spanish soldiers of the time many opportunities to win renown. The capture of the French king (Francis I.) at Pavia and his imprisonment at Madrid gratified for a moment the pride of the Spaniards, and did much to reconcile some of them to the sacrifices which the policy of the emperor imposed on them. But the *cortes* begged Charles many times to make an end of the European wars, as did the nobles assembled in 1538. Except in the case of the successful attack on Tunis in 1535, and the attempt to take Algiers in 1541, the actions of Charles were not inspired by any regard for the interests of his Spanish kingdoms. He treated them simply as instruments to promote the grandeur of his house. His indifference to their good, or his utter inability to see where it lay, was conspicuously shown when, on his abdication in 1556, he left his hereditary Flemish possessions to his son Philip, and not to his brother Ferdinand.

Philip II.—In foreign policy the reign of Philip II. (1556–98) was a prolongation of the reign of his father, and in it the vices of this policy were displayed to the fullest extent. Philip's marriage with Mary Tudor in 1554 having proved barren, and her death in 1558 having placed Elizabeth on the throne of England, he was left without the support against France which this union was meant to secure. At the same time his inheritance of the Netherlands brought him into collision with their inhabitants, who feared his absolutist tendencies, and with the Reformation (*q.v.*). The revolt in the Low Countries was inevitably favoured by both France and England. Philip was consequently drawn into intervention in the religious wars of France (*q.v.*) and into war with England, which culminated in the great Armada (*q.v.*) of 1588. His relations with England were further complicated by the extension of English maritime enterprise to the New World (*see* HAWKINS, JOHN; and DRAKE, FRANCIS). In the Mediterranean he was equally forced by his position and the tradition of the Crown of Castile to take part in resisting the Turks (*see* MALTA; and LEPANTO, BATTLE OF). But his relations with his Flemish subjects formed the centre of his policy. With his absolutist tendencies, which did not however differ from those of other European monarchs, he was bound to wish to govern them as he did Castile, and the principle of religious toleration, which was not understood by any prince in Europe with the exception of the prince of Orange, William I., the Silent (*q.v.*), was peculiarly impossible for him. His reign was therefore one long struggle with forces which he was unable to master.

The burden of the struggle fell with crushing effect on his Spanish dominions and particularly on Castile. Aragon, which was poor and tenacious of its rights, would give little; Catalonia and Valencia afforded small help. The Flemish revenue was destroyed by the revolt. The Italian states barely paid their expenses. Resources for the incessant wars of the reign had been sought in the taxation of Castile and the revenue from the mines of America. They were wholly inadequate, and the result of the attempt to dominate all western Europe was to produce bankruptcy and exhaustion. In his internal government Philip was fully absolute, but he was at the same time careful to ensure good administration, public integrity and justice.

Foreign Policy of Philip II.—The first years of the reign of Philip II. were occupied in concluding the last of his father's wars with France, to which was added a very unwelcome quarrel with the pope, arising out of his position as duke of Milan. He was unable to avoid sending an army under Alva against Paul IV., and was glad to avail himself of the services of Venice to patch up a peace. On the Flemish frontier, with the help of an English contingent and by the good generalship of Philibert of Savoy he defeated a French army at St. Quentin on Aug. 10, 1557, and again at Gravelines on July 13, 1558. But he did not follow up his successes, and the war was ended by the signing of the peace of Cateau Cambrésis on April 2, 1559. The exhaustion of his resources made peace necessary to him, and it was no less desirable to the French Government. Philip's marriage with Elizabeth, the daughter of Henry II. and of Catherine de' Medici, together with their common fear of the Reformation, bound him

to the French royal house, but for a brief period only.

By 1567 the revolt in the Netherlands was flagrant, and the duke of Alva was sent with a picked army, and at the expense of Spain, to put it down. In the same year, a decree of the king, which repeated the terms of another decree of Charles (1526) regarding the Catholic education of Moriscoes and the prohibition of the use of Arabic, led to a revolt which desolated Granada from 1568 to 1570. The Moriscoes had looked for help from the Turks, who were engaged in conquering Cyprus from Venice The danger to Spain and to the Spanish possessions in Italy stimulated the king to join in the Holy League formed by the pope and Venice against the Turks; and Spanish ships and soldiers had a great share in the splendid victory at Lepanto

In 1581 Philip annexed Portugal, as heir to King Henry, the aged successor of Dom Sebastian. Philip endeavoured to placate the Portuguese by the fullest recognition of their constitutional rights, and in particular by favouring the *fidalgos* or gentry The duke of Braganza, whose claims were better than Philip's, was bought off by immense grants Outwardly at the zenith of its powers, the country in reality was internally exhausted, and its weakness was shown when open war began with England in 1585.

While a vast armament was being slowly collected for the invasion of England, Drake swept the West Indies, and in 1587 burnt a number of Spanish ships in their own harbour of Cadiz. The ruinous failure of the great Armada in 1588 demonstrated the incapacity of Spain to maintain her pretensions. In 1591 the support given by the Aragonese to Antonio Perez (*q v*) led to the invasion of their country by a Castilian army. The constitutional rights of Aragon were not entirely suppressed, but they were diminished, and the kingdom was reduced to a greater measure of submission. In his later years Philip added to all his other burdens a costly intervention in France to support the League and resist the succession of Henry IV. to the throne. He was compelled to acknowledge himself beaten before his death on Sept 13, 1598 He left the war with England and with the Netherlands as an inheritance to his son

Philip III. 1598–1621.—The period of 102 years covered by the reigns of Philip III, Philip IV. and Charles II., was one of gradual decadence, mainly in the spheres of politics and economics. On the other hand and until the end of the reign of Philip IV it was the golden age of Spanish literature, art and science The dynasty continued to make the maintenance of the rights and interests of the house of Austria its main object. The policy of James I of England, the civil wars of Charles I, the assassination of Henry IV of France, the troubles of the minority and reign of Louis XIII and the Fronde (*q.v*), preserved Spain from concerted and persistent foreign attack. After a futile attempt to injure England by giving support to the earl of Tyrone in Ireland (*see* TYRONE, EARLS OF) peace was made between the powers in 1604. In 1609 a 12 years' truce was made with the Dutch But the temporary cessation of foreign wars brought no real peace to Spain

Philip IV. 1621–65.—The death of Philip III. (March 21, 1621) brought no real change. His son, Philip IV., was an abler man and even gave indications of a wish to qualify himself to discharge his duties as king. But he was young, pleasure-loving, and wanted the strength of will to make his good intentions effective For 20 years the administration was really directed by his favourite the count of Olivares (*q.v.*) and the duke of San Lucar, known as the "Conde-Duque," the count-duke. Olivares possessed the sense of the national unity of Spain as opposed to the particularism of the old kingdoms, which was a source of certain weakness in international disputes. But he could only keep his place by supplying his master with the means of dissipation and by conforming to his dynastic sentiments. The truce concluded in 1609 with Holland ended in 1621, and was not renewed. The commercial classes, particularly in Portugal, complained that it subjected them to Dutch competition. War was renewed, and the Dutch invaded Brazil. As their fleets made it dangerous to send troops by sea to Flanders, Spain had to secure a safe road overland. Therefore she endeavoured to obtain full control of the Valtellina, the valley leading from Lombardy to Tirol, and from thence to the German ecclesiastical states, which allowed a free passage to the Spanish troops War with France ensued. The failure of the treaty of marriage with England (*see* BUCKINGHAM, GEORGE VILLIERS, first duke of) also led to war, for the English court was offended by the Spanish refusal to aid in the restoration of the count palatine, son-in-law of James I, to his dominions In Flanders the town of Breda was taken after a famous siege The French conducted their campaign badly. The Dutch were expelled from Bahia in Brazil, which they had seized An English attack on Cadiz in 1625 was repulsed.

Decadence of the Spanish Empire.—But by 1640 the feebleness of the political power of the Spanish European empire was notorious In that year Portugal fell away without needing to strike a blow Then followed the revolt of Naples (*see* MASANIELLO) and of the Catalans, who were bitterly angered by the excesses of the troops sent to operate against the French in Roussillon They called in the French, and the Spanish Government was compelled to neglect Portugal Olivares, who was denounced by the nation as the cause of all its misfortunes, was dismissed, and the king made a brief effort to rule for himself But he soon fell back under the control of less capable favourites than Olivares In 1643 the prestige of the Spanish infantry was ruined by the battle of Rocroy At the Peace of Munster, which ended the Thirty Years' War in 1648, Spain was cynically thrown over by the German Habsburgs for whom she had sacrificed so much Aided by the disorders in the minority of Louis XIV, she struggled on till the Peace of the Pyrenees in 1659, by which Roussillon was ceded to France An attempt was now made to subdue Portugal, but the battle of Montesclaros in 1665 proved the futility of the effort The news of the disaster was followed by the death of the king on Sept. 17, 1665. Catalonia was saved by the reaction produced by excesses of the French troops, and in Naples the revolt had collapsed; but Portugal was lost forever.

Charles II. 1665–1700.—During the whole of the reign of Charles II, the son of the second marriage of Philip IV with his niece Mariana of Austria, the Spanish monarchy was saved from dismemberment only by the intervention of England and Holland. The wars of 1667–68, 1672–78, 1683–84, and the war of the League of Augsburg, 1689–96, were some of them fought wholly, and all of them partly, because the French king wished to obtain one or another portion of the dominions of the Spanish Habsburgs But Spain took a subordinate and often a merely passive part in these wars The king was imbecile During his minority the Government was directed by his mother and her successive favourites, the German Jesuit Nithard and the Granadine adventurer Fernando de Valenzuela. In 1677 the king's bastard brother, the younger Don John of Austria, defeated the queen's faction, which was entirely Austrian in sentiment, and obtained power for a short time By him the king was married in 1679 to Marie Louise of Orleans, in the interest of France When she died in 1689, he was married by the Austrian party to Mariana of Neuburg. At last the French party, which hoped to save the monarchy from partition by securing the support of France, persuaded the dying king to leave his kingdom by will to the duke of Anjou, the grandson of Louis XIV, and of Maria Teresa, daughter of Philip IV. by his first marriage. On the death of Charles II, on Nov 1, 1700, the duke of Anjou became king

THE BOURBON DYNASTY

The decision of Louis XIV. to accept the inheritance left to his grandson by Charles II led to a war (*see* SPANISH SUCCESSION, WAR OF THE), which was only ended in 1713 by the peace of Utrecht, and resulted in the loss of Gibraltar and the island of Minorca, which remained in the hands of England, and of all the Spanish dominions in Italy and Flanders

Philip V. 1700–46.—In internal affairs the years of the war were of capital importance in Spanish history. The general political and administrative nullity of the upper Spanish class of this generation and the political views of the French monarchy led to the assumption of all real power by the French or Italian servants and advisers of the king. Under their direction important finan-

cial and administrative reforms were begun. The absolutist and centralizing nature of some of these innovations revived the separatist tendencies of the eastern portion of the peninsula which had embraced the cause of the Austrian party against the Bourbon dynasty. Philip V. was forced to reduce Aragon, Catalonia and Valencia by arms. Barcelona was only taken in 1714, the year after the signing of the Treaty of Utrecht. Most of the privileges of these once independent kingdoms, which had with rare exceptions been respected by the Austrian kings, disappeared.

Elizabeth Farnese and Alberoni.—On the death of Philip V.'s wife, Maria Luisa Gabriella of Savoy, in 1714, the king was married at once to Elizabeth Farnese of Parma, who ruled him and used her whole influence to drag Spain into a series of adventures in order to obtain Italian dominions for her sons. Her first agent was the Italian priest Alberoni (*q.v.*), whose favour lasted from 1714 to 1719. Alberoni could not, and perhaps did not, sincerely wish to prevent the queen and king from plunging into an attempt to recover Sardinia and Sicily, which provoked the armed intervention of France and England and led to the destruction of the rising Spanish navy off Cape Pàssaro (*see* TORRINGTON, GEORGE BYNG, VISCOUNT). In 1731 Elizabeth secured the succession of her eldest son, Charles, afterwards Charles III. of Spain, to the duchy of Parma, by arrangement with England and the empire. Apart from the Italian intrigues, the most important foreign affairs of the reign were connected with the relations of Spain with England. A feeble attempt to regain Gibraltar was made in 1733, and a serious war was only averted by the resolute peace policy of Walpole. The king, who had become almost entirely mad, died on July 9, 1746.

Ferdinand VI. 1746–59.—His successor, Ferdinand VI., the second son of his first marriage, was a retiring and modest man, who adopted a policy of peace with England. His ministers were mainly Spaniards, well qualified for political and administrative tasks (which indicates a very rapid recovery), intermingled with a few foreigners: the most notable of the Spaniards was Zenon de Somadevila, marquis of Ensenada, and of the foreigners, Richard Wall, an Irish Jacobite. The advance of the country in material prosperity was considerable.

Charles III. 1759–88.—Charles III. was one of the most sincere, and the most successful, of the "enlightened despots" of the 18th century. He had had a long apprenticeship in Naples, and was a man of 43 when he came to Spain in 1759. Until his death he laboured to advance the material prosperity of Spain. His foreign policy was less wise. He had a deep dislike of England, not only because of the late wars in Europe, but also because of the covetous eyes which England turned on America; and a strong and justified desire to recover Minorca and Gibraltar. All this added to a natural family feeling, induced him to enter into the "Family Compact" with his French cousins. In 1770 he came to the verge of war with England over the Falkland islands. In 1778 he joined France in supporting the insurgent English colonists in America. The most statesmanlike of his foreign enterprises, the attempt to take the piratical city of Algiers in 1775, was made with insufficient forces and ended in defeat. Yet he was able to recover Minorca and Florida in the War of American Independence, and he finally extorted a treaty with Algiers which put a stop to piratical raids on the Spanish coast.

The king's domestic policy was almost wholly fruitful of good. Under his direction many useful public works were carried out—roads, bridges and large schemes of drainage. The first reforms undertaken had provoked a disturbance in Madrid directed against the king's favourite minister, the Sicilian marquis of Squillacci. Charles, who believed that the Jesuits had promoted the outbreak, and also that they had organized a murder plot against him, allowed his minister Aranda (*q.v.*), the correspondent of Voltaire, to expel the order in 1766, and exerted his whole influence to secure its entire suppression. The new spirit was also shown by the restrictions imposed on the numbers of the religious orders and on the Inquisition. On the other hand the shipping and the industry of Spain increased greatly. The population made a considerable advance, and, under the enlightened bureaucratic rule of Florida-blanca, the sloth and ignorance which had settled on Spain in the end of the 17th century was lifted.

Charles IV. 1788–1808.—Charles III. was succeeded in 1788 by his son Charles IV. The father, though "enlightened," had been a thorough despot; the son was sluggish and stupid to the verge of imbecility, but the despotism remained. The new king was much under the influence of his wife, Maria Luisa of Parma, a coarse, passionate and narrow-minded woman; but he continued to repose confidence in his father's ministers. Floridablanca was, however, unable to continue his earlier policy, in view of the contemporaneous outbreak of the Revolution in France. The revival of Spain depended on the restoration of her colonial and naval ascendancy at the expense of Great Britain, and for this the support of France was needed. But the "Family Compact," on which the French alliance depended, ceased to exist when Louis XVI. was deprived of power by his subjects. Of this conclusive evidence was given in 1791. Some English merchants had violated the claim of Spain to the whole west coast of America by founding a settlement at Nootka Sound. The Spanish Government lodged a vigorous protest, but the French National Assembly refused to lend any assistance, and Floridablanca was forced to conclude a humiliating treaty and give up all hope of opposing the progress of Great Britain.

The French Revolution.—This failure was attributed by the minister to the Revolution, of which he became the uncompromising opponent. He opened negotiations with the *émigrés*, urged the European Powers to a crusade on behalf of legitimacy, and paraded the devotion of Charles IV. to the head of his family. This bellicose policy, however, brought him into collision with the queen with the result that Floridablanca and his friends, and shortly afterwards the veteran Aranda also, were set aside and the favourite Emmanuel Godoy obtained the direction of affairs. Godoy, who had recently received the title of duke of Alcudia, and who was at once the queen's lover and the personal favourite of the king, had no experience of the routine of office, and no settled policy: but the course to be pursued was decided for him. The execution of Louis XVI. (Jan. 21, 1793) made a profound impression in Spain. Charles IV. was roused to demand vengeance for the insult to his family, and the Spanish monarchy became an enthusiastic member of the first coalition against France. But the campaign undertaken mainly in Roussillon was a failure; the Spaniards were driven from the strong fortresses that guarded the Pyrenees, whilst the French advanced almost to the Ebro.

The queen and Godoy hastened to follow the example set by Prussia, and concluded the Treaty of Basle with France (1795). But the moderation of this treaty was only a flimsy disguise of the disgrace that it involved. Spain found herself tied hand and foot to the French republic. Godoy had to satisfy his allies by the encouragement of reforms which both he and his mistress loathed, and in 1796 the veil was removed by the conclusion of the Treaty of San Ildefonso. This was a virtual renewal of the "Family Compact" of 1761, but with terms far more disadvantageous to Spain. The real object of the treaty was cynically avowed in the 18th article, by which, during the present war, the Spanish obligations were only to apply to the quarrel between Great Britain and France. A scheme was prepared for a joint attack on the English coast, but it was foiled by the battle of St. Vincent (*q.v.*), in which Jervis and Nelson forced the Spanish fleet to retire to Cadiz. Great Britain seized the opportunity to encourage discontent in the Spanish colonies.

It was in vain that Godoy sought to secure the friendship of the reforming party by giving office to two of its most prominent members, Jovellanos and Saavedra. Spanish pride and religious sentiment were offended by the French occupation of Rome and the erection of a republic in the place of the papal Government. The treatment of the duke of Parma by the Directory was keenly resented by the queen. Godoy found himself between two parties who agreed only in their hatred of him, and in March 1798 he was compelled to resign his office. Godoy's office was entrusted to Saavedra, but the reformers did not obtain the advantages which they expected from the change. During Napoleon's absence in Egypt the second coalition gained successes in 1799 which had seemed impossible since 1793.

Napoleon and Spain.—But the return of Bonaparte, followed as it was by the fall of the directory and the establishment of the consulate, commenced a new epoch for Spain. As soon as the first consul had time to turn his attention to the peninsula, he determined to restore Godoy, who had already regained the affection of the queen, and to make him the tool of his policy Maria Luisa was easily gained over by playing on her devotion to the house of Parma, and on Oct. 1, 1800 a secret treaty was concluded at San Ildefonso. Spain undertook to cede Louisiana and to aid France in all her wars, while Bonaparte promised to raise the duke of Parma to the rank of king and to increase his territories by the addition either of Tuscany or of the Roman legations. This was followed by Godoy's return to power Spain was now more servile to France than ever, and in 1801 was compelled to attack Portugal in the French interests. The Spanish invasion, commanded by Godoy in person, met with no resistance, and the prince ventured to conclude a peace on his own authority by which Portugal promised to observe a strict neutrality on condition that its territories were left undiminished. But Bonaparte resented this show of independence, and compelled Charles IV to refuse his ratification of the treaty In the preliminary treaty with Great Britain, Bonaparte ceded the Spanish colony of Trinidad without even consulting the court of Madrid, while he sold Louisiana to the United States in spite of his promise not to alienate it except to Spain. As soon as he saw himself involved in a new war with England, he turned to Spain for assistance and extorted a new treaty (Oct. 9, 1803), which was more burdensome still than that of 1796. Spain had to pay a monthly subsidy of 6,000,000 fr, and to enforce strict neutrality upon Portugal, this involving war with England The last remnants of its maritime power were shattered in the battles of Cape Finisterre and Trafalgar, and the English seized Buenos Aires.

Treaty of Fontainebleau.—In Oct 1807 Spain accepted the Treaty of Fontainebleau The treaty was hardly concluded when a French army under Junot marched through Spain to Portugal and the royal family of that country fled to Brazil Ferdinand, whose wife had died in 1806, determined to imitate his rival Godoy by bidding for French support He entered into secret relations with Eugène Beauharnais, Napoleon's envoy at Madrid, and went so far as to demand the hand of a Bonaparte princess Godoy, who discovered the intrigue, induced Charles IV to order his son's arrest (Oct. 27, 1807), on the charge of plotting to dethrone his father and to murder his mother and Godoy The prince indeed was soon released and solemnly pardoned; but, meanwhile, Napoleon had seized the opportunity afforded by this public scandal in lowering the prestige of the royal family to pour his troops into Spain, under pretext of reinforcing Junot in Portugal Even this excuse was soon dropped, and by Jan and Feb, 1808 the French invasion had become clearly revealed as one of conquest Charles IV. and his minister determined to fight The news of this intention, however, excited a rising at Aranjuez, whither the king and the queen had gone from Madrid A raging mob, instigated by highly placed people, surrounded the palace, clamouring for Godoy's head; and the favourite's life was only saved by Charles IV.'s announcement of his abdication in favour of Ferdinand (March 17). Murat, however, who commanded the French, refused to be turned aside by this change of circumstances He obtained from Charles IV. a declaration that his abdication had been involuntary, and occupied Madrid (March 23, 1808).

Napoleon Attacks Spain.—Meanwhile Napoleon had advanced to Bayonne on the frontier, whither, at his orders, Murat despatched the old king and queen and their favourite Godoy The emperor had already made up his mind to place one of his brothers on the Spanish throne; but in order to achieve this it was necessary to cajole the young king Ferdinand VII. and get him into his power. Ferdinand, instead of retiring to Andalusia and making himself the rallying point of national resistance, had gone to Madrid, where he was at the mercy of Murat's troops and whence he wrote grovelling letters to Napoleon. It was no difficult matter for the emperor's envoy, General Savary, to lure him by specious promises to the frontier, and across to Bayonne, where he was confronted with his parents and Godoy in a scene of pitiful degradation Struck and otherwise insulted, he was forced to restore the crown to his father, who laid it at the feet of Napoleon. The old king and queen, pensioned by the French Government, retired to Rome; Ferdinand was kept for six years under strict military guard at Talleyrand's château of Valençay (*see* FERDINAND VII, King of Spain) On May 13 Murat announced to an improvised "junta of regency" at Madrid that Napoleon desired them to accept Joseph Bonaparte as their king

The War of Independence.—But Spanish loyalty and sentiments of independence were too profound to be daunted For the first time Napoleon found himself confronted, not by terrified and selfish rulers, but by an infuriated people who rose against the French on that memorable day, May 2, 1808 The rising in Spain began the movement which ultimately proved fatal to Napoleon's power. At first he treated the novel phenomenon with contempt, and thought it sufficient to send his less prominent generals against the rebels Madrid was easily taken, but the Spaniards showed great capacity for the guerrilla warfare (*q v*) in the provinces The French were repulsed from Valencia; and Dupont, who had advanced into the heart of Andalusia, was compelled, by a force entirely composed of Spanish troops and volunteers, to retreat and ultimately to capitulate with all his army at Baylen (July 10). The Spaniards now advanced upon Madrid, and drove Joseph from the capital, which he had just entered

The Spanish nation, deprived of its kings and former statesmen and even of the support of a large part of the higher nobility, sought to build up a provisional political organization based on the old provincial and regional committees (*juntas*) It was a remarkable effort, and in spite of its many defects the admirable *bourgeoisie* and the provincial yeomanry succeeded in creating a system which proved capable of resisting French domination The military superiority of the French was so great that an immediate victory was impossible, but Napoleon himself was compelled to come to Spain to direct operations In less than a week the Spanish army was broken through and scattered, and Napoleon restored his brother in Madrid Sir John Moore, who had advanced with an English army to the relief of the capital, retired when he found he was too late, and an obstinate battle, in which the gallant general lost his life, had to be fought before the troops could secure their embarkation at Corunna Napoleon thinking the work accomplished, had quitted the peninsula, and Soult and Victor were left to complete the reduction of the provinces. The capture of Seville resulted in the dissolution of the central junta, but the patriots took refuge in Cadiz, which became the capital of independent Spain The peninsula was only saved from final submission by the obstinate resistance of Wellington in Portugal, the heroic conduct of many Spanish towns, such as Saragossa and Gerona, the continuous activity of the *guerrillas*, and by dissensions among the French.

The Cortes of 1810 and the Constitution of 1812.—The Spanish *cortes* had never been so entirely suspended as the States-General of France They had been encouraged to a certain extent during the 18th century to play a more important political rôle The reformist patriots of Cadiz, influenced by the ideas of revolutionary France, then conceived the plan of re-establishing the old Spanish parliaments on a more democratic and national basis In 1810 the new *cortes* in which the colonies were represented was convened. The third estate of the commons secured 184 representatives, who were sufficient to swamp the nobles and the clergy. In theory the members of the third estate had been chosen by a process of double election In fact, however, since much of the country was held by the French, they were often returned by such natives of the regions so occupied as happened to be present in Cadiz at the time. The suppression of the Inquisition and other measures relating to the privileges of the Church and the aristocracy passed together with much else But even before the new constitution was published and sworn, on March 19, 1812, large numbers of Spaniards had made up their minds that after the invaders were driven out the *cortes* must be suppressed.

Expulsion of the French.—Spain, in achieving her liberation from the military domination of France, owed very much to the

assistance of Great Britain (*see* PENINSULAR WAR). In 1812 Wellington determined on a great effort. He secured his base of operations by the capture of Ciudad Rodrigo and Badajoz, and at Salamanca he completely routed the opposing army of Marmont. This victory enabled the English general to enter Madrid (Aug. 12), and Joseph retreated to Valencia. But further advance was prevented by the concentration of the French forces in the east, and Wellington found it advisable to retire for the third time to winter quarters on the Portuguese frontier. It was during this winter that Napoleon suffered his first and greatest reverse in the retreat from Moscow and the destruction of his grand army. The "war of liberation" in Germany followed, and French troops had to be withdrawn from Spain to central Europe. For the first time Wellington found himself opposed by fairly equal forces. In the spring of 1813 he advanced from Ciudad Rodrigo and defeated Jourdan at Vittoria, the battle which finally decided the Peninsular War. Joseph retired altogether from his kingdom, and Wellington, eager to take his part in the great European contest, fought his way through the Pyrenees into France. Napoleon, who had suffered a crushing defeat at Leipzig, hastened to recognize the impossibility of retaining Spain by releasing Ferdinand VII., who returned to Madrid in March 1814.

Restoration of Ferdinand VII.—Before entering Spain Ferdinand had undertaken to maintain the constitution of 1812, and when on March 22, 1814 he reached Figueras, he was met by a demand on the part of the *cortes* that he must accept all the terms of the constitution as a condition of his recognition as a king. But Ferdinand had convincing proof of the true temper of the nation. He refused to recognize the constitution, and was supported in his refusal not only by the army and the Church, but by the masses. There can be no doubt that Ferdinand VII. could have ruled despotically if he had been able to govern well. But, although possessed of some sardonic humour and a large measure of cunning, he was base, and had no real capacity. He changed his ministers incessantly, and on mere caprice. Governed by a *camarilla* of low favourites, he was by nature cruel as well as cowardly, and the persecution of the "*liberales*" was ferocious.

Revolution of 1820.—Partial revolts took place, but were easily crushed. The revolt which overpowered him in 1820 began by a military mutiny. During the war the American colonies had rebelled, and soldiers had been sent to suppress them. No progress had been made, the service was dreadfully costly in life, and it became intensely unpopular among the troops. Meanwhile the brutality of the king and his ministers had begun to produce a reaction. Not a few of the officers held Liberal opinions, especially those who had been prisoners in France during the war and had been inoculated with foreign doctrines. These men, of whom the most conspicuous was Colonel Rafael Riego, worked on the discontent of the soldiers, and in Jan. 1820 brought about a mutiny at Cadiz, which became a revolution. Until 1823 the king was a prisoner in the hands of a section of his subjects, who restored the constitution of 1812 and had the support of the army. But the Liberals were divided into sub-sections; any sign of moderation on the part of the ministers chosen from one of them was enough to secure him the name of "*Servile*" from the others. The "*Serviles*" or absolutists proper took up arms in the north. Ferdinand appealed for help to the monarchies of the Holy Alliance. As early as 1820 the Emperor Alexander I. of Russia had suggested a joint intervention of the powers of the Grand Alliance to restore order in the peninsula, and had offered to place his own army at their disposal for the purpose. The project had come to nothing owing to the opposition of the British Government and the strenuous objection of Prince Metternich to a course which would have involved the march of a powerful Russian force through the Austrian dominions. In 1822 the question was again raised at the congress assembled at Verona (*see* VERONA, CONGRESS OF). The French Government asked to be allowed to march into Spain, as Austria had marched into Naples.

French Intervention, 1823.—In spite of the vigorous protest of Great Britain, which saw in this demand only a pretext for reviving the traditional Bourbon ambitions in the peninsula, the mandate was granted by the majority of the powers; and on April 7, 1823 the duke of Angoulême, at the head of a powerful army, crossed the Bidassoa. The result was a startling proof of the flimsy structure of Spanish Liberalism. What the genius of Napoleon had failed to accomplish in years, Angoulême seemed to have achieved in a few weeks. But the difference of their task was fundamental. Napoleon had sought to impose upon Spain an alien dynasty; Angoulême came to restore the Spanish king "to his own," and found the active support of some Spaniards and the tacit co-operation of the majority. The *cortes*, carrying the king with it, fled to Cadiz, and after a siege, surrendered with no conditions save that of an amnesty, to which Ferdinand solemnly swore before he was sent over into the French lines. As was to be expected, an oath taken "under compulsion" by such a man was little binding; and the French troops were compelled to witness, with helpless indignation, the orgy of cruel reaction which immediately began under the protection of their bayonets.

The Spanish Colonies.—If anything could have recalled the distracted country to harmony and order, it would have been the object-lesson presented by the loss of all its colonies on the continent of America, just as at an earlier date England had lost a great part of her American dominions. Some of them had already become *de facto* independent after 1810 and many more in the ten years following, and the recognition of their independence *de jure* was, for Great Britain at least, merely a question of time. When the Angoulême invasion of Spain was seen to be inevitable, Canning had informed the French Government that Great Britain would not tolerate the subjugation of the Spanish colonies by foreign force. A disposition of the powers of the Grand Alliance to come to the aid of Spain in this matter was countered by the famous message of President Monroe (Dec. 2, 1823, *see* MONROE DOCTRINE), laying the veto of the United States on any interference of concerted Europe in the affairs of the American continent. The republics of Mexico and Colombia were recognized by Great Britain in the following year; the recognition of the other states was only postponed until they should have given proof of their stability.

The Succession Question.—In Spain itself, tutored by misfortune, the efforts of the king's ministers, in the latter part of his reign, were directed to restoring order in the finances and reviving agriculture and industry in the country. The king's chief difficulties lay in the attitude of the extreme monarchists (*Apostólicos*) who found leaders in the king's brother Don Carlos and his wife Maria Francisca of Braganza. Yet the absolute monarchy would probably have lasted for long if a dispute on the succession had not thrown one of the monarchical parties on the support of the Liberals. The king had no surviving children by his first three marriages. By his fourth marriage (1829) with Maria Cristina of Naples he had two daughters. According to the ancient law of Castile and Leon women could rule in their own right, as is shown by the examples of Urraca, Berengaria and Isabella the Catholic. When he died on Sept. 29, 1833, his daughter Isabella II. was proclaimed queen, with her mother Maria Cristina as regent.

The Regency of Cristina.—Maria Cristina would have ruled despotically if she could, and began by announcing that material changes would not be made in the method of government. But the Conservatives preferred to support the late king's brother Don Carlos, and they had the active aid of the Basques, who feared for their local franchises, and of the mountaineers of Navarre, Aragon, Catalonia and Valencia. Maria Cristina had the support of the army, and the control of the machinery of government. The regent soon found that this was not enough to enable her to resist the active hostility of the Carlists and the intrigues of their clerical allies. She was eventually driven by the necessities of her position to accept parliamentary institutions.

The Carlist Wars.—The first civil war, which for the Crown was a dynastic war, and for the nation a struggle between two opposed political principles, was terminated in Aug. 1839 by the convention (*convenio*) of Vergara between the Carlist general Maroto and the Liberal general Espartero. The Carlist general Cabrera, the most famous of the *guerrilleros* of his party, left the country. The political struggle was then for some years confined to Government circles; but already a part of the common people

had been won over to the cause of Liberalism. In 1841 a crisis arose, the immediate cause of which was a law depriving the towns of a great part of their autonomy Queen Cristina resigned and fled to France, and General Espartero was declared regent He held office till 1843, during an agitated period, in which the Carlists reappeared in the north, mutinies were common, and an unsuccessful attempt was made on the part of the enemies of Espartero to kidnap the young queen in her palace on the night of Oct 7, 1841. In 1843 Espartero, a man of much personal courage and of fitful energy, but of no political capacity, was expelled by a military rising, promoted by a combination of discontented Liberals and the Moderates The queen, though only 13 years old, was declared of age.

Isabella II.—The reign of Queen Isabella, from 1843 till her expulsion in 1868, was no more than a prolongation of her mother's regency It was a confused conflict between the attempts of the court to rule despotically, with a mere pretence of a *cortes*, and the growing wish of the Spaniards for a parliamentary Government, or at least the honest and capable Government which they hoped that a parliament would give them During this period a series of political changes, revolutions and amendments to the constitution took place, a detailed account of which is unnecessary The party leaders were almost always generals. Espartero, Narvaez (leader of the Moderates, who were conservatives of almost absolutist ideas), O'Donnell and Prim The only event which diverted public interest from questions of domestic politics was the war in Morocco in 1859, in which the armies of Spain were victorious, but which led to but meagre results in North Africa owing to the intrigues of other European Powers whose interests were involved. Another event of international importance was the queen's marriage in 1846 Louis Philippe, perceiving a chance of reviving the family alliance between Bourbon France and Bourbon Spain, with the aid of the queen-mother succeeded in forcing Isabella to accept the hand of Don Francisco d'Assisi, her cousin, who was notoriously incapable of having heirs, and on the same day the younger sister was married to the duke of Montpensier, son of Louis Philippe Palmerston had agreed to this union—but not until an heir to the Spanish Crown should have obviated the possibility of the French prince again inheriting the throne of Spain The affair broke the entente between France and England, and was a contributory cause of the downfall of Louis Philippe

In Sept 1868 the squadron at Cadiz under the command of Admiral Topete mutinied, and its action was the signal for a general secession One gallant fight was made for the queen at the bridge of Alcolea in Andalusia by General Pavia, but it was an exception Gonzales Brabo deserted her in a panic She went into exile, and her reign ended The revolution of 1868 was the first openly and avowedly directed against the dynasty It became a familiar saying that the "spurious race of Bourbon" had disappeared forever, and the country was called upon to make a new and a better Government.

Contending Parties.—The mass of the Spaniards, however, were not prepared for a republic. There were also the various monarchical parties. the *Alfonsins* who wished for the restoration of the queen's son with a regency; the partisans of the widower king consort of Portugal, those of the duke of Montpensier, the Carlists; and a few purely fantastic dreamers who would have given the crown to the aged Espartero The real power was in the hands of the military politicians, Francisco Serrano (*q v*) and Juan Prim (*q.v.*), who kept order by means of the army A constituent *cortes* was assembled in 1869, and decided in favour of a monarchy. The constitution of 1869 was the first in the constitutional history of Spain since 1812, which clearly set forth the entire programme of the liberalism of the period. Serrano was declared regent until a king could be found.

Amadeo of Savoy.—At last, in Aug 1870, Prince Amadeo of Savoy, second son of Victor Emmanuel II., consented to become candidate He was elected on Nov. 3. On Dec. 27, 1870, the day on which the new king reached Carthagena, Prim was murdered by assassins who were never discovered. The nominal reign of Amadeo lasted till Feb. 1873. It was a pitiful episode He had put himself into a false position. Intriguing politicians sought to use him as a tool, and every man of honest principles, royalist or republican, looked upon him as an intruder The Carlists began to collect in the mountains. Republican agitation went on in the towns. At last a dispute in regard to the officering of the artillery gave the king an honourable excuse for resigning the throne

Republican Interlude.—The Republicans entered the place he left vacant simply because there was nobody to oppose them Until Jan 1874 the country was given up to anarchy The Carlists increased rapidly, and were joined by many Royalists, who looked upon them as the last resource A new *cortes* was collected and a new constitution discussed Three presidents succeeded one another within a year, Pi y Margall, Salmeron and Castelar: ministries changed every few days As the republic was to be federal when finally organized, many parts of Spain proceeded to act independently One party went beyond federalism and proposed to split Spain into cantons The Cantonalists seized the important harbour of Carthagena and the ships in it The ships were taken out of their hands by the British and German squadrons The spectacle of anarchy, and the stoppage in payment of taxes frightened the Republican deputies into some approach to sanity Salmeron allowed General Pavia to restore order in Andalusia When he gave place to Castelar, the eloquent Republican deputy threw all his most eagerly avowed principles to the wind, raised a great conscription, and provided the means of reducing Carthagena and pushing the war against the Carlists with vigour When the *cortes* met again in Jan 1874, the extreme parties voted against Castelar on the 3rd of the month Hereupon General Pavia, the governor of Madrid, turned the *cortes* into the streets Serrano was appointed as head of the executive, and was mainly employed during the year in efforts to save Bilbao from falling into the hands of the Carlists It had now become clear that the restoration of the Bourbons in the person of Don Alphonso, Isabella's son, was the only way of securing a final settlement On Dec 29, 1874, General Martinez Campos caused him to be proclaimed king at Murviedro (Sagunto) by a brigade of troops, and the example there set was followed everywhere Don Alphonso XII landed in Barcelona on Jan 10, 1875

THE RESTORED MONARCHY

Alphonso XII.—The first act of Alphonso was a royal decree confirming the appointment of Cánovas del Castillo (the most prominent leader of the *Alfonsins*) as prime minister A strong administration was formed, which gave its attention for 15 months to the pacification of the peninsula, adopting a Conservative and Catholic policy which contributed quite as much as the great display of military resources to lose the Carlists adherents and prestige The Church, the nobility and the middle classes soon pronounced for the new state of things The Alphonsist armies, led by Marshals Campos and Jovellar, swept the Carlist bands from the right bank of the Ebro to the Pyrenees, and took their last strongholds in the east of Spain, Cantavieja and Seo de Urgel Some of the Carlist leaders accepted bribes to go abroad, and others put their swords at the disposal of the Government for employment against the Cuban rebels Then all the forces of King Alphonso under Marshal Quesada closed round the remainder of the Carlist army in Navarre and in the Basque Provinces at the beginning of 1876 That was the end of the Carlist Wars

The Cuban Insurrection.—Directly this internal strife was over, the government used part of the large army at its disposal to reinforce the troops which had been fighting the Cuban insurgents since 1869 Marshal Jovellar was sent out to Havana as governor-general, with Marshal Martinez Campos as commander-in-chief of the forces. In about 18 months they managed to drive the rebels into the eastern districts of the island, Puerto Principe and Santiago de Cuba, and induced all but a few irreconcilable chiefs to accept a convention that became famous under the name of the Peace Treaty of Zanjon Marshal Campos, who succeeded Jovellar as governor-general, held out to the loyalists of the island the prospect of reforms, fairer treatment at the hands of the mother country, a more liberal tariff to promote their trade, and self-government as the crowning stage of the new policy

Internal Changes.—Though much of his time and energies had been devoted to the re-establishment of peace at home and in the colonies from 1875 to 1880, Cánovas had displayed considerable activity and resolution in the reorganization of the monarchy. Until he felt sure of the early termination of the struggle, he ruled in a dictatorial manner without the assistance of parliament. Royal decrees set aside most of the legislation and reforms of the Spanish revolution. Universal suffrage alone was respected for a while and used to call into existence the first *cortes* of the Restoration in 1876. The principal result of this parliament was the constitution of 1876, which was a compromise between the constitution of 1845 in the reign of Isabella and the principles of the democratic constitution of the revolution in 1869. Cánovas, who was endowed with great political qualities, sought at the same time to win over to the new régime some of the old Liberals of the Revolution, and the least recalcitrant of the old Carlists. The latter (including Don Alejandro Pidal and his followers) eventually joined the ranks of the Conservative Party adding to it a leaven which, however, was not always in harmony with the views of the prime minister. The Liberals succeeded in forming a dynastic Liberal Party whose name of *Fusionista* was indicative of the great heterogeneity of its component elements.

After a short-lived marriage with his cousin Mercedes, third daughter of the duke of Montpensier, Alphonso listened to the advice of his council and married the Austrian archduchess Maria Cristina of Habsburg.

The Liberal Government.—In 1881 the *Fusionista* Party, swelled by the addition of a number of Liberal and Conservative generals who disapproved of Cánovas' policy, showed unmistakable signs of agitation. Cánovas himself thought that the time had come to slacken somewhat the reins of conservative hegemony and to allow effective expression to the support given to the dynasty by the so called Liberal Party whose leader was Sagasta, the former minister of King Amadeo. In this way the latter party came into power. The policy of Sagasta in domestic affairs resembled that of Cánovas. Several treaties of commerce were concluded with European and Spanish American Governments. They reformed the tariff in harmony with the treaties, and with a view to the reduction of the import duties by quinquennial stages to a fiscal maximum of 15% *ad valorem*. A general conversion of the consolidated external and internal debts was promoted by a considerable reduction of capital and interest, to which the bondholders assented. The floating debt proper was consolidated in the shape of a 4% stock redeemable in 40 years, of which £70,000,000 was issued in 1882 by Señor Camacho, the greatest Spanish financier of the period. Sagasta was not so fortunate in his dealings with the anti-dynastic parties, and the Republicans gave him much trouble in Aug. 1883. This had the effect of gaining him the support of many Democrats and Radicals who broke away from Ruiz Zorrilla the leader of the revolutionary republicans. But Sagasta himself had to abandon the premiership. A new cabinet formed by members of the "Fusionist" left wing did not last long. In 1884 Cánovas returned to power.

The last Conservative cabinet of this reign was neither popular nor successful. In the *cortes* the tension in the relations between the Government and the Opposition was growing daily more serious. Outside, the Republicans and Carlists were getting troublesome, and the tone of their press vied with that of the Liberals in their attacks on the Conservative cabinet.

Regency of Queen Cristina.—The declining health of the king had been kept as secret as possible, and in the ten months before his death the Conservative cabinet displayed unprecedented rigour against the newspapers of every shade: in 60 days 1,260 prosecutions were ordered against Madrid and provincial papers. But at last, on Nov. 24, 1885, the truth had to be admitted and on the morning of the 25th the end came. It was no wonder that the death of the king should have made Spaniards and foreigners extremely anxious about the prospects of the monarchy. Alphonso XII. left no male issue. He had two daughters, the princess of the Asturias, born in 1880 and the Infanta Maria Theresa, born in 1882. At the time of his death it had not been officially intimated that the queen was *enceinte*. The *Official Gazette* did not announce that fact until three months after the demise of the sovereign. On May 17, 1886, six months after the death of Alphonso XII., his posthumous son, Alphonso XIII. was born at the palace of Madrid. The political situation was difficult. Cánovas assured the queen-regent that he was ready to undertake the Government if it was thought wise to continue the Conservative policy of the late king, but in the circumstances he frankly advised that Señor Sagasta should be asked to take the reins of government, with a view to inaugurating the regency under a progressive and conciliatory policy.

Sagasta.—Sagasta took for colleagues for the first Liberal cabinet some of the strongest and most popular statesmen of the party, virtually representing the three important groups of men of the Revolution united under his leadership—veteran Liberals like Camacho and Venancio Gonzalez; Moderates like Alonzo Martinez, Gamazo and Marshal Jovellar; and Democrats like Moret, Montero Rios and Admiral Beranger. The new cabinet convoked the *cortes* elected under the administration of Cánovas in 1884; and supplies and other bills were voted to enable the government to be carried on until another parliament could be elected in the following year, 1886.

The field was thus fairly clear for an accentuation of the Catholic policy which the queen mother had at heart. She became regent when Spain had felt the consequences of the expulsion of the Jesuits and other religious orders from France after the famous Jules Ferry laws, which aimed at placing these orders once more under State control, to which they declined to submit. They selected Spain as an excellent field of enterprise; and all the Governments of the regency showed so much indulgence towards the Catholic revival thus started, that in less than a decade the kingdom was studded with convents and monasteries.

Progress.—The prime minister conducted the first general election in 1886 much after the usual precedents. The long parliament of the regency was composed of considerable Liberal majorities in both houses, though Sagasta had allowed a larger share than Cánovas was wont to do to the minorities; on the Opposition benches Republicans of various shades were represented by their most eminent leaders, the Carlists had a respectable group, and the Conservatives a strong muster, flanked by a group of dissentients. The first *cortes* of the regency in five sessions did really good and substantial work. A civil code was carefully drawn up by Alonzo Martinez, in order to consolidate the heterogeneous ancient legislation of the monarchy, especially in the old kingdom of Castile; while at the same time measures were taken to ensure respect for the local civil laws of many provinces, especially Catalonia, Aragon, Valencia, Navarre and the Basque territory. Trial by jury was re-established for most crimes and offences. The laws regulating the rights of association and public meeting, the liberty of the press and other rights of the subject were reformed on liberal and more tolerant lines.

Republican Movement Fails.—In these circumstances, a Republican movement which was suddenly launched in Sept. 1886 by the partisans of Ruiz Zorrilla collapsed at its very outset. Very shortly afterwards the war minister, General Castillo, attempted to strike at the root of military insubordination, and simultaneously in every garrison of the kingdom the senior sergeants, more than 1,000 in all, were given their discharge and ordered to their homes at once. No trace of revolutionary work is visible among non-commissioned officers after 1886. As time wore on, Sagasta found it difficult to maintain discipline in the ranks of the Liberal Party. Señor Martos and the Democrats almost brought about a political crisis in 1889. Sagasta cleverly affected to resign and stand aside, but without him a Liberal Government was impossible. On his return to power, Sagasta reconstructed his ministry for the last time, and announced his intention to make the re-establishment of universal suffrage the crowning act of the Liberal policy, knowing very well that he would thus rally round him all the Liberals, Democrats and most of the Republicans in the last session of the long parliament. The suffrage bill was carried through the senate and congress in the spring of 1890 after protracted debates, in which the Conservatives and many military politicians did their best to

obstruct the measure. The increasingly violent opposition of the Conservatives was supported by the regency and accordingly Sagasta, after having secured the promulgation of the law of universal suffrage, resigned at the first hint given him by the queen (July 1890).

A Protectionist Regime.—Cánovas once more returned to power and gathered round him most of the prominent Conservative and Catholic statesmen. The first step of the new cabinet was to adopt protection. Sagasta to please Señor Gamazo and the Liberal representatives of agricultural interests, had allowed his parliament to empower the Government to revise and increase all tariff duties not covered by the then existing treaties of commerce. This touched most of the products of agriculture and live stock, so Cánovas and his finance minister, by royal decree, enormously increased the duties on these imports, and particularly on breadstuffs. Then, in 1891, they denounced all the treaties of commerce which contained clauses stipulating most-favoured-nation treatment, and put in force in Feb. 1892 a protectionist tariff which completely reversed the moderate free-trade policy which had been so beneficial to the foreign commerce of Spain from 1868 to 1892. The effects of this policy verging upon prohibition were soon sharply felt. Foreign exchanges rose, exports decreased, the railway traffic declined, and the commercial classes and consumers of foreign goods and products were loud in their protests. Industrial interests alone benefited, and imported more raw materials, chemicals and coal and coke, which naturally influenced the exchanges adversely. But political divisions also began to show themselves in an acute form within the Conservative Party, chiefly owing to the rivalry between Cánovas' two lieutenants, Romero Robledo and Silvela (Francisco). Once more Cánovas had to resign and Sagasta, with great reluctance, succeeded him.

The two most important events of this new period of "fusionist" Government took place outside the peninsula. The scene of one was the Spanish zone in Morocco bordering the Riff, the tribes inhabiting which had never submitted to the authority of the sultan and had always been very bad neighbours. An incursion by these tribes into Spanish territory and an attack upon Spanish troops resulted in the defeat of the latter and the death of General Margallo who was in command Public opinion was instantly fired, and the press called so loudly for revenge that the Government sent to Melilla no less a personage than Marshal Campos, at the head of 29 generals and 25,000 men The sultan of Morocco lost no time in censuring the behaviour of the Riff tribes, and in promising that he would chastise them. Marshal Campos was sent to Fez to make a treaty, in which he obtained ample redress and the promise of an indemnity of £800,000 which Morocco punctually paid.

The Cuban Question.—Colonial affairs gave Sagasta much to do. Señor Antonio Maura, the colonial minister, and Señor Gamazo, the finance minister, two moderate Liberals, attempted together to grapple with colonial questions, which in 1894 had assumed a very serious aspect. Marshal Campos, on returning from Cuba in 1870, had advocated some concessions to satisfy the legitimate aspirations of the majority of the colonists In 1886, in the first parliament of the regency, Cuban autonomist deputies (who had issued their first political programme in Aug. 1878) divided the house on a motion in favour of home rule and of an extension of the franchise in Cuba This motion was negatived by all the Conservatives, by most of the Dynastic Liberals and by some of the Republicans The majority of Spaniards were prevented by the Government and the press from learning of the disaffection in Cuba, so that they were loath to listen to the few men, courageous enough to raise the note of alarm during the ten years before the final catastrophe. For no other reason did Maura, in 1893, fail to convince the *cortes*, and even the Liberal Party, that his very moderate Cuban Home Rule bill was indispensable.

In succession to Maura, Señor Abarzuza framed a Cuban Reform bill (1895) so much short of what his predecessor had thought an irreducible minimum of concessions, that it was censured in Havana by all the colonial Liberals and home rulers, and by their representatives in Madrid The latter at the last moment recorded their votes in favour of the Abarzuza bill when they perceived that a strange sort of eleventh-hour presentiment was about to make all the Spanish parties vote this insufficient reform. Before it could be promulgated, the tidings came of a separatist rising in the old haunts of Creole disaffection near Santiago de Cuba (1895). Sagasta then sent about 12,000 men to reinforce the 15,000 soldiers in Cuba under General Calleja, and was preparing more when a sudden attack made by officers of the Madrid garrison upon the offices of the radical paper *El Resumen* raised a question of discipline with which the authorities were unable to deal in the manner required by law. The impotence of the authorities on this occasion, which was the forerunner of many others, resulted in the return to power of the Conservatives.

Cánovas devoted his attention to the Cuban question, and sent out General Martinez Campos who had been so successful in 1878. He allowed him much liberty of action, but dissented on the expediency of offering the loyalists of Cuba as much home rule as would not clash with the supremacy of Spain. The prime minister declared that the Cubans must submit first, and then the mother country would be generous. This policy rendered inevitable the failure of the efforts of Campos, who took an entirely different view of the question

Weyler in Cuba.—Cánovas then sent to the island General Weyler, who favoured purely military measures, sternly and harshly applied He certainly cleared two-thirds of the island of Creole bands, and stamped out disaffection by vigorous military operations and by obliging all the non-combatants who sympathized with the rebels in arms to elect between joining them in the bush (*la Manigua*) or residing within the Spanish lines This system, which was disavowed in Spain by most Liberals, might probably have succeeded if American supplies had not reached the rebels in considerable quantities, and if American diplomacy had not again and again made representations against Weyler's ruthless policy of repression in the island.

Cánovas so fully comprehended the necessity of averting American intervention that he listened to the pressing demands of secretary Olney and of the American minister in Madrid, Hannis Taylor, and laid before the *cortes* a bill introducing home rule in Cuba on a more liberal scale than Maura, Abarzuza and Sagasta had dared to suggest two years before. Cánovas did not live to see his scheme put into practice, as he was assassinated by an anarchist at the baths of Santa Agueda, in the Basque Provinces, on Aug 9, 1897. The queen-regent appointed General Azcárraga, the war minister, as successor to Cánovas; and a few weeks later President McKinley sent General Woodford as representative of the United States at the court of Madrid At the end of Sept. 1897 the American minister placed on record, in a note handed by him at San Sebastian to the minister for foreign affairs, the duke of Tetuan, a strongly-worded protest against the state of things in Cuba, and demanded in substance that a stop should be put to Weyler's proceedings, and some measures taken to pacify the island and prevent disturbances which, he said, grievously affected American interests. Less than a fortnight after this note had been delivered, the Conservative cabinet resigned, and the queen-regent asked Sagasta to form a new administration.

Weyler Recalled.—The Liberal Government recalled Weyler, and sent out, as governor-general of Cuba, Marshal Blanco, a conciliatory and prudent officer who agreed to carry out the home-rule policy, concerted by Señor Moret and by Sagasta Had things not already gone too far in Cuba, and if public opinion in the United States had not exercised irresistible pressure on both Congress and President, the Moret Home-Rule Act (Nov 1897) would probably have sufficed All through the winter of 1897–98 the Madrid Government took steps to propitiate the United States, even offering a treaty of commerce which would have allowed American commerce to compete on equal terms with Spanish imports in the West Indies and defeat all European competition But the blowing up of the American cruiser "Maine" in the port of Havana added fuel to the agitation in the United

States against Spanish rule in Cuba, and war followed. When Congress met in Washington the final crisis was hurried on. Spain appealed to European mediation, to the pope, to courts and Governments, but none were disposed to go beyond purely platonic representations at Washington.

War with the United States.—At last, on April 20, 1898, when the Spanish Government learned that the United States minister, General Woodford, had been instructed by telegraph to present an ultimatum demanding the cessation of hostilities in Cuba, with a view to prepare for the evacuation of the island by the Spanish forces, Sagasta decided to give General Woodford his passports and to break off official relations with the United States. It was an open secret that this grave decision was not taken at the cabinet council presided over by the queen without a solemn protest by Moret and the ministers of war and marine that the resources of Spain were totally inadequate for a struggle with the United States. These protests were overruled by the majority of the ministers, who invoked dynastic and monarchical considerations in favour of a desperate stand, in defence of the last remnants of the colonial empire of Spain.

The sequel is soon told. The Spanish fleet in the Far East was defeated in Manila bay by Admiral Dewey. Admiral Cervera's squadron was destroyed outside the bay of Santiago de Cuba by the United States fleet under Admirals Sampson and Schley. All communication between Spain and her colonies was thus cut off. A U.S. expedition landed near Santiago, and the Spanish garrison surrendered after a fortnight's show of resistance. Shortly afterwards, at the end of July, Spain sued for peace through the mediation of French diplomacy.

End of New World Rule.—The agreement of Aug. 9, signed by M. Cambon, the French ambassador in Washington, in the name of Spain, clearly stipulated that her rule in the New World must be considered at an end, and that the fate of the Philippines would be settled at the Paris negotiations. Spain could not help assenting to a treaty by which she renounced unconditionally all her rights of sovereignty over Cuba and Porto Rico and ceded the Philippine islands and Sulu islands and the largest of the Marianne islands in consideration of the payment of twenty million dollars by America. Thus ended a struggle which only left Spain the Carolines and a few other islands in the Pacific, which she sold to Germany in 1899 for £800,000, and a couple of islands omitted in the delimitation made by the Paris peace treaty of Dec. 12, 1898, and purchased by the United States in 1900.

After the War.—The Liberal Government was held responsible for the *débâcle,* but the seeds had been sown long before by many and widely diffused mistakes and by hostile influences outside Spain; the cabinet of 1898, moreover, had sought to avert it by every means in its power. The result was that a call was again made upon the Conservatives, then led by Silvela, who was far from possessing the qualities necessary to control the situation and to stem the pessimism which overwhelmed the majority of Spaniards. His one real success was achieved for him by the economic policy of his minister of finance, Villaverde, who succeeded in less than 18 months in giving a decisive and vigorous impulse to the reorganization of the budget, and of the home and colonial debts. He resolutely reformed all existing taxation, as well as the system of assessment and collection, and before he left office he was able to record an increase of close upon three millions sterling in the ordinary sources of revenue. His reorganization of the national debt was very complete; in fact, he exacted even more sacrifices from the bondholders than from other taxpayers. The amortization of the home and colonial debts was suppressed, and the redeemable debts of both classes were converted into 4% internal consols. The interest on all colonial debts ceased to be paid in gold, and was paid only in pesetas, like the rest of the internal debts, and like the external debt held by Spaniards. Alone, the external debt held by foreigners continued to enjoy exemption from taxation, and its coupons were paid in gold; but the Government consented to a conversion of the 4% external debt into a $3\frac{1}{2}$% stock redeemable in 61 years. (A. E. Ho.; R. Al.)

Growth of Religious Orders.—The failure of Silvela compelled the queen once more to summon Sagasta (March 1901). He was at once faced with two problems, very opposite in their nature, which were destined to play a very conspicuous part in Spanish politics. The first was that presented by the growth of the religious orders and congregations, which continued to increase in number and power and had ignored the law of associations of June 1887, which ordered congregations to register their members, and required all except three orders admitted under the concordat to apply for authorization. The queen-regent, on July 19, 1901, issued a decree, countersigned by Sagasta, for enforcing the law.

Industrial Unrest.—Meanwhile, however, a second and more pressing peril distracted the attention of the Government. The industrial unrest, fomented by Socialist agitation, culminated in Jan. 1902 in serious riots at Barcelona and Saragossa, and on Feb. 16 in the proclamation of a general strike in the former city. The government sent General Weyler to deal with the situation; and order was restored. The methods by which this result had been achieved were the subject of violent attacks on the Government in the *cortes,* and on March 13 Sagasta resigned, but only to resume office five days later. He now returned to the question of the religious orders, and on April 9 issued a decree proclaiming his intention of enforcing that of July 19, 1901. The attitude of the Church was practically one of defiance. The nuncio, indeed, announced that the papacy would be prepared to discuss the question of authorization, but only on condition that all demands for such authorization should be granted. To avoid a crisis at the time when the young king was about to come of age, the Government yielded; and on May 20, Sagasta announced that a *modus vivendi* had been established.

Alphonso XIII.—King Alphonso XIII., whose enthronement took place with all the antique ceremonial on May 17 was himself at the outset under clerical and reactionary influences, and his contemptuous treatment of ministers—who at the ceremonial functions were placed wholly in the background—seemed to argue an intention of ruling personally under the advice of the court *camarilla.* This impression, due doubtless to the king's youth and inexperience, was belied in the event; but it served still further to discredit the Liberal Government. On Nov. 7 Sagasta resigned, resumed office temporarily on the 14th, and handed in his final resignation on Dec. 3. On Dec. 6 a Conservative cabinet was formed under Silvela, the portfolio of finance being taken by Villaverde.

The first years of the new reign saw a renewal of the rivalries between the leaders of both parties, Conservative and Liberal alike, the latter temporarily breaking up when, on Jan. 5, 1903, Sagasta died. The result was a period of frequent changes of Government: the conservative Governments of Villaverde and Maura, and the clerical-conservative Government of Azcarraga, in 1904, the Liberal Governments of Montero Rios and Moret in 1905. The country meanwhile was in a ferment, the old antagonisms, due to the conflict of interests between the industrial north and the agricultural south and to the traditional regional, social and religious conflicts, being now complicated by socialist and anarchist agitation.

The king's marriage with Princess Victoria Eugénie, which took place on May 31, was in many respects significant. In spite of the young queen's "conversion" and the singular distinction conferred on her by the papal gift of the golden rose, the "Protestant" alliance marked a further stage in Alphonso XIII.'s emancipation from the tutelage of the Clerical-Conservative court, which looked with disfavour on the marriage. The king was, indeed, showing an increasing tendency to think and act for himself, which, though not as yet overstepping constitutional limits, was disconcerting to all parties.

Ecclesiastical Controversies.—The political situation soon assumed a serious aspect when the new cabinet presided over by General Lopez Dominguez, a democrat, obtained the king's signature to an ordinance giving, in conformity with the spirit of the law, legal validity to the civil marriages of Catholics. This aroused a furious agitation among the clergy, to which bounds were only set by the threat of the Government to prosecute the

bishop of Tuy and the chapter of Cordova. In the session 1906–07 the most burning subject of debate was the new Associations Law, drawn up by the minister Señor Davila. Even in the Liberal ranks the question aroused furious differences of opinion; Señor Montero Rios, the president of the senate, denounced the "infamous attacks on the church"; the Government itself showed a wavering temper in entering on long and futile negotiations with the Vatican; while in Jan 1907 the cardinal archbishop of Toledo presented a united protest of the Spanish episcopate against the proposed law. This and other issues produced complete disunion in the Liberal party. Already, on Nov 27, Lopez Dominguez had resigned; his successor, Moret, had at once suffered defeat in the house and been succeeded in his turn on Dec 4 by the marquis de la Vega de Armijo The question was now mooted in the cabinet of dropping the Associations Law; but on Jan 21, 1907 Señor Canalejas, president of the lower house, who was credited with having inspired the bill, publicly declared that in that event he would cease to support the Government By the 24th the cabinet resigned, and a Conservative Government was in office under Señor Maura as premier

Maura's Ministry 1907–1909.—During his second period of political power Maura gave a clear indication of his qualities and aims, which were to exercise a powerful influence upon affairs. Though a sincere Catholic, he was no Clerical, as was proved by his refusal to withdraw the ordinance on civil marriage. The main objects that he set before himself were, firstly, the maintenance of order; secondly, the reform of local government, so as to destroy the power of the *caciques* and educate the people in their privileges and responsibilities. The local administration reform bill was submitted to the *cortes* in Oct 1907. It contained 429 clauses, largely increased the responsibility of the local elected bodies, made it compulsory for every elector to vote, and did away with official interference at the polls. The bill met with strenuous opposition, and on Dec 23, 1907 the *cortes* adjourned without its having been advanced

Political Tension Renewed.—But in the following year the struggle between the antagonistic forces in Spain once more produced a perilous crisis The Local Administration bill, after being debated for two sessions, passed the lower house on Feb 13, 1909, having at the last moment received the support of the Liberal Señor Moret, though the Radicals as a whole opposed it as a sop to Señor Cambó, the Regionalist leader, and tending to disintegration It was however evident that the method of Señor Maura, who ruled in the spirit of an enlightened despotism rather than in that of a constitutional government, could not meet with the approval of Liberals at all events it was inevitable that he should incur unpopularity in many quarters. His efforts to reconstruct the Spanish navy were attacked both by the apostles of retrenchment and by those who saw in the shipbuilding contracts an undue favouring of the foreigner, the Marine Industries Protection Act was denounced as favouring the large shipowners and exporters at the expense of the smaller men. The cabinet's ecclesiastical policy also exposed him to the fate of those who take the middle way; the Liberals denounced the minister of education, Don F. Rodriguez San Pedro, for making concessions to the teaching orders, while the archbishops of Burgos and Santiago de Compostella fulminated against the Government for daring to tax the congregations In his reforming work Maura had an active and efficient lieutenant in the minister of the interior, Señor La Cierva. Under his auspices laws were passed reforming and strengthening the police force, instituting industrial tribunals, regulating the work of women and children, introducing Sunday rest, early closing and other reforms. In short, the position of the Government, when the *cortes* adjourned on June 6, 1909, seemed to be assured.

Morocco Crisis and the Barcelona Rising.—Its downfall was ultimately due to the development of the crisis in Morocco (*q v*). It is only here proposed to outline the effects of its reaction upon the internal affairs of Spain. The trouble, long brewing, broke out in July, with the attack by the Riff tribesmen upon the workmen engaged on the railway being built to connect Melilla with the mines in the hills, held by Spanish *concessionares* The necessity for strengthening the Spanish forces in Africa had for some time been apparent, but Maura had not dared to face the *cortes* with a demand for the necessary estimates, for which, now that the crisis had become acute, he had to rely on the authorization of the council of State The spark was put to the powder by the action of the war minister, General Linares, in proposing to organize a new field force by calling out the reserves This summoned up too vivid memories of the useless miseries of former over-sea expeditions On July 26 a general strike was proclaimed at Barcelona, and a movement directed at first against "conscription" rapidly developed into a revolutionary attack on the established order in Church and State The city, a *colluvies gentium*, was seething with dangerous elements, its native proletariat being reinforced by a cosmopolitan company of refugees from other lands The mob, directed by the revolutionary elements, attacked more especially the convents and churches From the city the revolutionary movement spread to the whole province In Barcelona the rising was suppressed after three days' street fighting (July 27–29). On the 28th martial law was proclaimed throughout Spain, and a military reign of terror continued until the end of September In the fortress of Monjuich in Barcelona were collected, not only rioters caught red-handed, but many others—notably journalists—whose opinions were disliked The greatest sensation was caused by the arrest on Aug 31 of Señor Ferrer, a theoretical anarchist well known in many countries for his anti-clerical educational work and in Spain especially as the founder of "lay schools" Señor Ferrer was tried by court martial (Oct 11–13), and shot This tragedy, which rightly or wrongly aroused the most widespread indignation throughout Europe, produced a ministerial crisis in Spain The opening of the October session of the *cortes* was signalized by a furious attack by Moret on Maura and La Cierva, who were accused of having sacrificed Ferrer to the resentment of their clerical task-masters The Government had been already weakened by the news of Marshal Marina's reverse in Morocco (Sept 30), to this new attack it succumbed, Señor Maura resigning on Oct. 21, 1909

Moret Ministry, 1909–10.—On the 22nd the formation of a new cabinet under Señor Moret was announced. It sent General Weyler to keep Barcelona in order, caused the release of most of the prisoners in Monjuich, reduced the forces in Morocco, reopened negotiations with Rome for a modification of the concordat, and on Dec 31, the end of the financial year, was responsible for the issue of a royal decree stating that the budget would remain in force until the *cortes* could pass a new one. But, meanwhile, the municipal elections, under the new Local Administration law, had resulted in a triumph of the Liberals (Dec 12). Moret therefore considered the time ripe for a dissolution; the king, however, refused to consent, and on Feb. 9, 1910 the ministry resigned The new cabinet, with the radical Señor Canalejas as president of the council, included members of the various Liberal and Radical groups

Canalejas Ministry, 1910–12.—Señor Canalejas was regarded as a sincere Liberal who was determined to carry out the programme of the Left, especially with regard to the so-called clerical question and that of the *latifundia* of certain parts of Spain There was, however, in some quarters a doubt as to whether he had force of character enough to overcome his difficulties. This doubt was dispelled In the course of 1910 and 1911 certain indications showed that his policy might be successful.

The Clerical Question.—As regards the clerical question, it was not long before the Government showed that it was in earnest On May 31 the official *Gaceta* published a decree setting forth the rules to which the religious associations would have to submit. It was pointed out that, in conformity with the decree of April 9, 1902, it had become necessary to coerce those congregations and associations which had not fulfilled the formalities prescribed by the law of 1887, and also those engaged in commerce and industry which had not taken out patents with a view to their taxation.

In the speech from the throne at the opening of the new *cortes* (June 16) the king declared that his Government would "strive to give expression to the public aspirations for the reduction and

control of the excessive number of orders and religious orders, without impairing their independence in spiritual matters," and in introducing a bill for the amendment of the law of 1887. Señor Canalejas declared that the Government, "inspired by the universal spirit of liberty of conscience," had given to article xi. of the constitution "the full sense of its text."

Religious Toleration.—"Liberty of conscience," a principle condemned by the Syllabus of 1864 and discountenanced by the encyclical *Pascendi gregis* of 1905, was hardly a phrase calculated to conciliate the Spanish clergy, still less the Vatican. A cry went up that to allow dissident Churches to announce their presence was to insult and persecute the Catholic Church; at Rome the decree was attacked as unconstitutional, and as a breach of diplomatic propriety all the more reprehensible since negotiations for a revision of the concordat were actually pending. A violent clerical agitation, encouraged by the Vatican, was started, 72 Spanish archbishops and bishops presenting a joint protest to the Government. Fuel was added to the fire by the introduction of a bill—known as the "Cadena's bill"—forbidding the settlement of further congregations in Spain until the negotiations with the Vatican should have been completed. This was denounced at Rome as a unilateral assertion on the part of the Spanish Government of an authority which, under the concordat, belonged to the Holy See as well. As a preliminary to negotiation, the Government was required to rescind all the obnoxious measures.

This demand broke the patience of the prime minister, and on July 30, Señor de Ojeda, Spanish ambassador at the Vatican, was instructed to hand in his papers. In Vatican circles dark hints began to be dropped of a possible *rapprochement* with Don Jaime, who had succeeded his father Don Carlos, on July 18, 1909, as the representative of Spanish legitimacy and Catholic orthodoxy. The pretender, indeed, disclaimed any intention of stirring up civil war in Spain; his mission would be to restore order when the country should have wearied of the republican régime whose speedy advent he foresaw. The fulfilment of the first part of this prophecy seemed to some to be brought a step nearer by the overthrow of the monarchy in Portugal on Oct. 5, 1910. For Spain its immediate effect was to threaten a great increase of the difficulties of the Government, by the immigration of the whole mass of religious congregations expelled from Portugal by one of the first acts of the new régime.

(W. A. P.; R. AL.)

Morocco.—At the close of the year 1910 Señor Canalejas resigned in order to reconstruct his cabinet. This second ministry lasted till April 3, 1911, when it fell on the occasion of a debate on the Ferrer case.

The attention of parliament was diverted towards Moroccan affairs. The French were preparing their advance on Fez, and Spain was forced to an active policy, the first signs of which were received with ill-humour by the French press. The Government, in the teeth of popular opposition, were sending troops to Morocco, and on June 9 a Spanish force landed at Larache. France was prevented from taking strong action by the Agadir incident (*see* MOROCCO; EUROPE, etc.), but a certain tension prevailed between France and Spain during the summer.

The Moroccan operation prepared as a consequence of the disembarkation in Larache began successfully on Dec. 6, but collapsed a few days later after a gallant attempt to force the passage of the River Kert, not without leaving behind an atmosphere of ill-feeling due to the belief, current in the Spanish army, that the Moorish troops were provided with French arms and ammunition. Under such unfavourable conditions began the negotiations for a Franco-Spanish agreement following upon the Franco-German treaty on Morocco. After a reshuffling of his cabinet (March 11) Canalejas adjourned parliament until May 1.

With the summer a period of strikes, culminating in a grave railway strike, set in. Canalejas met it by applying article 221 of the Recruiting Law allowing the drafting into military service of all men of military age working in industries of public importance in cases of danger or abnormal circumstances. On Oct. 14 the autumn session began with a fresh discussion of the bill *de Mancomunidades*, but the session was brought to a close by the murder of Canalejas on Nov. 12, 1912 by a fanatical anarchist, an event which ended all the hopes placed in a statesman who, in less than three years and in spite of all the difficulties which had arisen, had given politics a distinctly liberal trend.

The Romanones Ministry.—Señor Canalejas was succeeded by Count de Romanones, one of his ministers, but the discipline of the Liberal Party, which had been maintained by the strong hand of the murdered premier, subsequently relaxed. Señor Maura, who had hoped to be asked to form a government, protested against the continuation in power of the Liberals. This was the first sign of a determined opposition. Señor Alvarez, on the other hand, took the opportunity to accentuate his evolution towards the monarchy, helped by the king, who, at the moment, was seeking the advice of several prominent men known for their advanced views. Count Romanones took a good share of whatever merit there was in this policy, as well as in the success of the king's official visit to Paris on the conclusion of the Franco-Spanish treaty (May 6–9). He resigned on May 31, after a strong speech of opposition from Maura who restated his position of "implacable hostility" to a policy of co-operation with the parties of the anti-dynastic Left. The next day the king asked Romanones to return once more, after the crisis caused by a split in the Liberal Party on the question of the bill *de Mancomunidades* then before the Senate (June 11). But this time it was generally realized that this step was simply an expedient necessitated by the coming visit of the French president to Madrid.

The latent Liberal crisis broke out as soon as M. Poincaré left Spanish soil. On Oct. 25 the cabinet resigned, and the king, after attempting in vain to reconcile the parties, realized that the Liberal policy which he had constantly followed since 1909 was at an end. He first summoned Maura but found his views on policy so dangerous that he turned to Señor Dato (Oct. 27), a choice which initiated the disintegration of the Conservative party. The new Government granted a decree giving validity of law to the bill *de Mancomunidades*, dissolved the *cortes* (Dec. 31, 1913), and came back after a general election with a sufficient majority in both houses. It met with considerable opposition owing to several royal decisions which were interpreted as acts of personal power in military matters. But its internal difficulties were soon to be merged into the all-absorbing preoccupation of the World War.

THE WORLD WAR AND AFTER

The international situation of Spain at the outbreak of war was defined by two sets of circumstances: official, and national or popular. The official situation was ruled by an agreement between Spain, France and England, made at Cartagena in 1907, and confirmed by the conversations held there in 1913 between M. Poincaré and Count Romanones, which stipulated that "should new circumstances arise tending to alter the territorial *status quo*" in the Mediterranean or in the European and African coasts of the Atlantic, the three Powers concerned would "enter into communication" in order to take any measures that might be necessary. The war was obviously a "circumstance" within the limits of the above definition, yet France and England, the two Powers most interested, made no sign. Señor Dato promptly declared for an absolute neutrality. Spain was the only European nation which had no stake in the war; the nation was divided in its feelings. The working classes, most of the intellectuals and the trading communities, were pro-Ally. The clergy, most of the army and of the bureaucracy and the "idle rich," were pro-German. The division cut across the parties. On one definite point everybody agreed. Spain was to keep out of the war.

A "committee of initiative" was created for the study and co-ordination of efforts to deal with war problems. Parliament resumed its sittings on Oct. 30, 1914 and unanimously endorsed the foreign policy of the Government.

A crisis caused by difficulties in connection with the launching of a loan brought about the resignation of the Government (June 22) quickly followed by a reinstatement of the same cabinet. The situation of the Treasury was by no means flourishing. At the end of the year revenue remained at 1,202,000,000 pesetas

while expenses, not including Government purchases of foodstuffs, rose to 1,556,000,000 pesetas. The Government had to fall back on Treasury bonds negotiated through the Bank of Spain. Yet the work of the country was in full swing under the stimulus of war orders. Profits in shipping rose high and sinkings by German torpedo boats increased accordingly. Señor Dato's Government fell on a debate on the Military Reform bills (Dec. 6, 1915). The crisis ended in the formation of a united Liberal ministry under Count Romanones.

Count Romanones wore his neutrality with a difference, and did little to conceal his pro-Ally views. By Sept 1916, Spain had lost more than 30,000 tons of shipping by torpedoing, and more than 50,000 in circumstances which were, to say the least, obscure. The shipping interests asked for Government help. On Jan. 31 Germany sent in a note establishing an "absolute blockade" of the Allied coasts. Count Romanones sent a firm answer on Feb. 6 But he realized that his firmness meant nothing unless backed with the will to fight if necessary and that public opinion would not follow him so far. He resolved to leave the Government there and then, at the top of the wave of his own policy.

Committees of Defence.—In resigning (April 19) he took the easiest path His fall, however, cost him the leadership of his party. The new ministry, under the premiership of Señor Garcia Prieto, was frankly neutralist It had moreover to concentrate on the situation created by the so-called committees of defence Towards the middle of 1916, a system of infantry committees of defence appeared, which soon evinced a tendency to interfere with the Government in such a manner that, towards the end of the year, Count Romanones, then in office, insisted on their dissolution General Aguilera, the war secretary in Garcia Prieto's administration, ordered the leaders to be arrested but, probably owing to royal hints, the order was cancelled, the army officers having meanwhile faced the Government with an ultimatum (June 1). The Government resigned Dato, called to office, capitulated before the juntas This victory of a movement which, in its essence, was revolutionary, stimulated the revolutionary ferment at work in the country Political manifestos asking for a renovation in government and constitution followed each other (Socialists June 12, Catalanists June 16, Left-Coalition June 16)

In the teeth of Government opposition, an assembly of senators and deputies met, voted resolutions asking for a reform of the constitution, and set up three commissions to prepare reports on reforms to be submitted to a second meeting to take place later These men might have taken the lead of the revolutionary spirit stirred by the army But the mass of the assembly was too dull, and no real leader manifested himself. Thus two attempts, one military, one middle-class, both directed against the evils of the old régime, failed through lack of co-ordination and mutual understanding. A third failure was still to come On Aug 10 the railwaymen of the Northern railway went on strike. On the 13th, a general strike, clearly revolutionary, was suddenly launched in the whole country.

A state of war was declared, and the military crushed the rebellion with a ruthless hand By Aug 19 the situation was well in hand. The net result was to prove that the only real force in the country was the army committee system. On Aug 10, the council of ministers passed a special credit for military expenses The committees attempted to deliver a message into the hands of the king. Dato had to resign on a "perfectly constitutional" hint by the king In point of fact he was expelled by the army committees. The crisis was long and laborious, and in the midst of it, the parliamentary assembly met in Madrid (Oct 30) in its second session. The cabinet was at last formed by Garcia Prieto It was a coalition ministry composed of Maurists, Liberals and Catalanists, in which, in order to give satisfaction to the new demand for an impartial general election, a non-political judge was given the post of home secretary Señor La Cierva, who took the war office, was the real head of the cabinet His policy consisted of ingratiating himself with the committees of defence, so as to become their leader and representative. But soon after the general election (Feb. 24) the Government fell on a grave crisis brought about by a strike of telegraph officials All possible combinations were tried and failed, until on March 21 at midnight, at a meeting of ex-prime-ministers called by the king in his study, King Alfonso, after, it is said, having threatened his abdication, succeeded in forming a "ministry of all the talents." It was but short-lived (resigned Nov 6). The new Government, presided over by Garcia Prieto, was formed amid the sensation caused by the news of the Kaiser's flight. It fell on Dec 3, 1918, and Count Romanones formed a stop-gap cabinet His first important act was his visit to President Wilson, then in Paris

The successive Governments which ruled Spain during this period had succeeded in steering clear of obstacles, home and foreign, overburdened as they were with home problems and foreign advice not always disinterested Unwelcome visits of German submarines (1917), and the requirements of trade (Anglo-Spanish agreement Dec 6) gradually brought Spain to apply to Germany the claim of ton for ton Germany had agreed to the ton-for-ton indemnity when the end of the war came. The Spanish merchant marine had lost 65 ships representing 140,000 tons. From the material point of view, the neutral attitude adopted by Spain contributed to accelerate the progress which was observable in her economic development in the pre-war years

Decay of the Party System.—A mixture of two political currents, a democratic, constitutional agitation, born of the Allied victory, and a revolutionary agitation traceable to the effect of the juntas' *pronunciamentos*, brought about a violent conflict between the military and the civil authorities of Barcelona The Government resigned, the military having expelled the civil authorities from the town. Maura took office on April 15, asked for a decree dissolving the *cortes*, and to the consternation of all parties, obtained it This amounted almost to a *coup d'état* on the part of the king

Maura, despite most objectionable methods, failed to bring to the new *cortes* more than about one-eighth of its total membership under his banner His Government fell (July 20), and Señor Sanchez de Toca (Dato being ill) formed a Conservative cabinet Two short-lived cabinets followed and a period of deep unrest, murders and mutinies (Saragossa, Valencia, Santander). The king called Dato to power But the general election at the end of 1920 showed that the mainspring of the old system—the docility of the electorate to any kind of Government—could no longer be counted upon Dato failed to obtain a working majority, his supporters numbering 177 members out of 405 All his efforts were accordingly bent towards the reconciliation of the several factions within the Conservative party While engaged in this task he was assassinated by anarchists on March 8, 1921

This murder accelerated the disintegration of the system of rotation of the two political parties, which, as arranged by Cánovas and Sagasta at the death of Alfonso XII., had stood the monarchy in good stead as a substitute for a real constitutional practice on the lines of the English monarchy While the old system deteriorated day by day owing to its own internal weakness, it was attacked from the outside by forces of three different kinds: first, the anti-dynastic elements, once heaped together under the common name of republicans, now moving towards Socialism on the one hand and on the other towards different varieties of social revolutionaries such as syndicalists, anarchists and even professional agitators without any political or philosophic bias; secondly, the Catalan home-rulers, gradually evolving from autonomy to separatism, finally the movement of what might be called military syndicalism embodied in the *juntas de defensa* A Conservative Government under Allendesalazar took office at Dato's death.

Morocco.—The military disaster which the Spanish troops met in Morocco in July 1921, beginning with the fall of the advanced post of Anual, entailed the withdrawal at heavy cost of the Spanish troops from all the zone previously occupied by the commanding officer in Melilla, the suicide of General Silvestre, and considerable moral effects both in Spain and in the Rif. It swept away the Allendesalazar Government. A stronger Conservative Government was constituted under Maura who, backed by public opinion, sent 140,000 men to the rescue of the troops in Morocco. But an energetic demand for an inquiry

made itself heard. As a set-off against this current of civilian opinion, the *juntas de defensa* began a campaign of threats and accusations against parliament, which they held responsible for the general disorganization leading to the Moroccan crisis. Injudiciously met by the Government at first, this demand had to be satisfied, and the Government decided to appoint General Picasso as an official investigator. General Picasso carried out his task with a high sense of duty and impartiality, and his report was received by all parties alike as a fine example of patriotism.

But this display of energy on the part of the Government increased the opposition of the military *juntas de defensa.* The cabinet sought a clumsy solution of this problem by a so-called "disbandment" of the *juntas* and their replacement by *juntas informativas* publicly and legally recognized and placed, at least in theory, under the authority of the war minister. This solution satisfied nobody. Señor Maura resigned in Jan. 1922, and though he continued in office by express wish of the king, had finally to disappear in March of the same year, leaving office to another Conservative cabinet under the leadership of Sánchez Guerra.

The Juntas.—The new prime minister, an energetic man, strongly opposed to the *juntas,* took office at a time when parliament was exceedingly weak. The *juntas de defensa* of the infantry officers, authorized by the previous war minister, adopted a number of resolutions, two of which are an indication of their general attitude: (1) Every infantry officer to be bound to affiliate to the *juntas,* or otherwise to be prosecuted before a tribunal of his brother officers; (2) No promotion to be authorized in the army save by seniority. The army officers had thus set up a form of military syndicalism which, owing to the material strength that it wielded, was a State within the State, while in parliament the opposition grew more critical of military inefficiency. The Picasso report was submitted to a parliamentary commission on which all the parties were represented. Parliament and public opinion grew more insistent in their demands for a condign punishment of the Moroccan setback and the Government collapsed.

Liberals and Morocco.—The Liberal coalition which, created in April of the same year, then took office (Dec. 1922) made it clear that it would uphold the parliamentary procedure adopted in regard to the conduct of the Moroccan campaign. Popular feeling backed the new Government.

The election held in April 1923 led to a Liberal-Reformist majority, but its sensational feature was the success of five out of eight Socialist candidates in securing election in the capital, attributed by the Socialist party to the strong line which they had taken against the war in Morocco.

The burden which the Moroccan question imposed on the Treasury was aggravated by other problems which the nation was unable to put aside. The railways were face to face with a severe crisis. The economic situation had somewhat improved since 1920–21, when the tension between owners and men was at its highest, particularly in Catalonia, where professional agitators victimized both owners and men to such an extent that in the year 1921 there were in Catalonia alone 145 attempts on human life causing 90 deaths.

Primo de Rivera.—In Sept. 1923, the report of the parliamentary commission on the disaster of 1921 was ready. Several politicians were stated to be deeply involved, some because they had accorded too much unconstitutional initiative to the king: other difficulties were raised owing to the ill-feeling with which the army received any parliamentary or civilian criticism of its action in Morocco. While the nation was anxiously awaiting the next development, a dramatic stroke brought suddenly to an end the system under which the country had lived since 1875. The captain-general of Catalonia, Don Miguel Primo de Rivera (Marqués de Estella) rebelled against the Government, threatened its members with gaol, and seized power first and office afterwards. He had already once or twice appeared in the limelight owing to declarations on such questions as the surrender of Morocco, on which he held courageous if unorthodox views, and on the interchange of Gibraltar and Ceuta. This last expression of opinion had caused his removal from the position of military governor of Cadiz which he then occupied. At the time of the *coup d'état* General Primo de Rivera was captain-general of Catalonia, his headquarters being in Barcelona.

In the early morning of Sept. 13, the Government published the news that the captain-general of Catalonia had risen in arms. The king was in San Sebastian. The military authorities of Bilbao and Saragossa had sided with the rebels and in Madrid, where the captain-general, General Muñoz Cobos maintained a cautious, though dubious attitude, a council of military commanders were acting for Primo de Rivera. A manifesto published the same day by Primo de Rivera declared that it was indispensable to liberate the country "from the professional politicians, the men who, for one reason or another, are responsible for the period of misfortune and corruption which began in 1898 and threatens to bring Spain to a tragic and dishonourable end." The general added that "the wide net of greedy politics has caught in its meshes and imprisoned the royal will itself." He announced the constitution of a military directorate in Madrid which was to find for the problem of Morocco a "quick, dignified and sensible" solution and was to bring home responsibility "promptly and justly" by the formation of "tribunals of recognized moral authority."

Immediately after the king's arrival (delayed 24 hours) the prime minister called on his majesty and proposed strong action against the military rebels, but the king asked for time for reflection and the Government resigned. Two hours later a deputation of generals was received at the palace and the king requested Primo de Rivera, still in Barcelona, to take office. Upon his arrival in Madrid on Sept. 15, Primo de Rivera proceeded to transform the provisional military directorate both in its personnel and in its constitution in order to grant representation in it to all the branches and all the garrisons of the army.

From a constitutional and administrative point of view, the directorate struck an original note. The only minister was Primo de Rivera himself and ministerial departments were left in charge of permanent officials. The directors studied specific questions. The Home Office was entrusted to General Martinez Anido, with the rank of under-secretary of State. Public opinion received the change in absolute silence, save for a protest from the Socialist Party.

The directorate declared the country in a state of war. The press was put under a strict censorship and all public demonstrations of a political character were forbidden. A few drastic measures enabled the new Government to gain control over the provincial and political machinery. In order to forestall possible trouble in the lower ranks of the army, a substantial rise in pay was granted to non-commissioned officers. A heavy budget, amounting to 54,000,000 pesetas, was set aside for Morocco.

On Nov. 13, two months after the *coup d'état,* Count Romanones and Don Melquiades Alvarez, the presidents respectively of the senate and of the congress of deputies, called on the king in order to remind him that the Crown was under a personal constitutional obligation to call the *cortes* together within three months of their dissolution. They were promptly dismissed by both king and prime minister. The king and his premier went on an official visit to the court of Italy in Nov. 1923. Both recorded their approval of and good wishes for the success and methods of Fascismo. Thus the king declared to General Italo Balbo: "I admire Fascismo. You are happy here in being so near the end of your labours. We are just beginning." In the Vatican, the king read a sensational speech which met with considerable criticism, not only in Vatican circles but also in Spain and South America. Spain was offered to His Holiness in the event of a new crusade being necessary. The answer of the pope was a discreet, broad-minded pronouncement.

Home Affairs.—The Government continued to repress all hostile expression of opinion. The agitation for an inquiry into the Moroccan campaign remained active and had for its centre the Ateneo de Madrid. The directorate closed the club—the first time since its creation in the second half of the 19th century. Don Miguel de Unamuno (*q.v.*), the famous author and professor of Salamanca university, whose strong stand against the directorate, expressed in indignant and sometimes offensive

articles in the press of South America, had greatly incensed the directorate, was exiled to the Canary islands.

In March 1924, the council of national economy was created in order to co-ordinate the activities of numerous economic organizations working under several departments. It was divided into six sections: tariffs, valuation of goods for tariff purposes, statistics, commercial information, defence of production, treaties of commerce The Treasury was heavily burdened with military and Moroccan expenditure. In April 1924, an internal loan was floated (700,000,000 pesetas of four-year-term bonds at 5% and 1% sinking-fund) in order to meet the Treasury bonds issued by them in Oct. 1923. This loan was covered nearly eight times over. In 1923 a national railway council was organized in order to co-ordinate the administration of the railway companies, the State and the companies sharing in the administration and the State participating in the financial liabilities and assets of the companies The Government launched a railway loan (Oct 1925) to the amount of 300,000,000 pesetas at 5% free from tax, with a lesser success due to unfavourable economic circumstances.

New Phase in Morocco.—The problem of Morocco soon monopolized the attention of the president. The expenses continued to increase. The budget of 1923–24 had to face a deficit of 576,000,000 pesetas, compared with a deficit of 920,000,000 in the budget of 1922–3, and of 1,101,000,000 for 1921–2. The decrease in the deficit in 1923–4 was not due to a reduction in expenses, but to a considerable increase in receipts due to the rise in the assessment of the tax on *utilidades* (a kind of tax on incomes) and to a better assessment of local and urban taxable property As for the year 1924–25, while financial papers estimated the deficit at 1,000,000,000, the directorate declared that it did not go beyond 600,000,000. General Primo de Rivera tackled the problem of Morocco with characteristic courage In the summer of 1924 he decided to carry out a considerable withdrawal and a reduction of military liabilities. Primo de Rivera steadfastly resolved to carry out his policy and he deserves credit for having succeeded, first in imposing his views on the Spanish army in the field at the risk, not only of his popularity, but even sometimes of his life, and also in conducting a difficult military retreat covering all the zone between Tetuan and Xauen Later events, however, obliged him considerably to modify his policy The sudden attack launched in 1925 by Abd-el-Krim against the French forces in the French protectorate, led to the combined action of the two countries The French Government sent to Spain M Malvy, who negotiated with General Primo de Rivera an agreement for military and political co-operation which led to the recovery of the French territory lost during the first onslaught of the Rifian troops, and to the occupation of Abd-el-Krim's headquarters, after a brilliant landing in Alhucemas Bay by the Spanish troops (*See* further the special article on MOROCCO.)

Municipal Reform.—In 1925 the directorate undertook a reorganization of the provincial and municipal administration of the country in two decrees. The first establishes a system of municipal autonomy, delegating to municipalities the right to levy certain rates, thus enabling them to set up their municipal treasuries; and establishing female and proportional suffrage in municipal institutions. The second deals with provincial administration, incidentally abolishing the *mancomunidad,* a kind of Catalonian local parliament. In its Catalonian policy the directorate soon reversed the pro-home-rule orientation which had inspired the first utterances of Primo de Rivera evidently inspired in the desire to ensure support from the Conservative home-rule elements of Catalonia for his *pronunciamiento* But Primo de Rivera found considerable opposition amongst the military forces which surrounded him to any measures of Catalan devolution, so that gradually the sympathies of the directorate towards the Catalonian autonomist movement made way for a régime described in Catalonia as one of systematic persecution.

On Dec. 2, Primo de Rivera parted from his military team and formed a ministry of which, apart from himself and the ministers of war and marine, a fourth soldier was a member in the person of Martinez Anido, who became home secretary and vice-president of the council. The other members of the cabinet were for the most part young and unknown men drawn from the extreme right of the old party system. Primo de Rivera however, in becoming president of the council, declared that he meant to retain full powers as dictator, and in particular, that the press was to remain under strict censorship He was true to his word. In 1926 both the press and individuals were strictly censored, especially in Catalonia, where one eminent professor was exiled

Foreign Affairs.—1926 was a year of diplomatic activity. In January a Spanish aviator flew from Spain to Buenos Aires and received an enthusiastic welcome from the Argentine republic The event had considerable moral effect in all Spanish America. It was quickly followed by a flight to Manila (March) which thus gave to the flying activities of Spain a definite meaning towards maintaining the moral connection with the lands which once had belonged to the empire. Abd-el-Krim, hard pressed by the combined efforts of the French and the Spaniards, surrendered to the French army commander (May) Meanwhile Spain had claimed a permanent seat in the Council of the League of Nations in fulfilment of repeated promises made by the French and the English Governments The position became confused, Brazil, Poland, China and Persia having also put forward similar claims, while Germany and the northern nations led by Sweden opposed all such increases in the number of permanent seats. The matter had to be adjourned till the June Council when Spain's usual representative, Señor Quiñones de Leon, was ominously absent On Aug. 9 the treaty with Italy was signed stipulating mutual neutrality in case of unprovoked aggression If not in its actual wording, which is innocuous, the treaty as an "act" does embody a new orientation in Spanish foreign policy and carried beyond the frontier the obvious conclusion to be drawn from the internal policy adopted, not by the country, but by the men in power. As if further to stress this independent mood Primo de Rivera in the same month announced his intention of asking for a drastic change in the Tangier Convention which amounted to the setting up of a Spanish protectorate in Tangier Thus the questions of the League Council seat and of the Spanish position in Tangier became simultaneously acute The Assembly and the Council of the League in Dec. 1926, decided to set up a special kind of Council seat of a semi-permanent character, making it quite clear that it was meant to meet the case of Spain The Government, however, refused such a compromise and gave notice of withdrawal (September). Three months later (Feb 1927) the foreign secretary resigned and the prime minister took over the Foreign Office

Home Affairs.—The year had been no less active in home affairs The president spent the first part of the year in propagandist efforts to set up an organization, the *Unión Patriótica,* which in his mind was to include all men of good will ready to accept his motto· "Country, Religion, Monarchy" His ministers undertook their several activities unfettered by any parliamentary or constitutional shackles. Good work was at once seen in the ministry of labour led by a young yet experienced Catalan, Señor Aunós, who tackled the organization of labour on a co-operative basis with effective vigour The department of public works was ably conducted by an expert, the Marqués of Guadalhorce. A welcome sign of economic revival came spontaneously from the nation. The *Confederación del Ebro,* a free association of all the public bodies interested in the river from its source to the sea, was founded in order to adjust the several requirements of irrigation, power, water supply and navigation as between all the regions on the river and its tributaries It proved a signal success and other bodies of a similar nature have been created since on other rivers Ambitious schemes for the electrification of the railways and the repair and development of the roads (including the construction of special roads for fast motor traffic) have been set on foot The main trouble comes from the censorship of the Press In June 1926, a plot was discovered against the régime It was led by Marshal Weyler, General Aguilera and several politicians The Government settled the matter with commendable tact and even with mischievous shrewdness as shown in the decision to fine

heavily the Liberal leader, Count Romanones. In September the president was faced with the gravest of the crises he had to meet. A decree (July 1926) having abolished the tradition jealously maintained by all the artillery officers never to accept promotion otherwise than by seniority the artillery officers protested, and after delicate negotiations an arrangement was arrived at by which the artillery officers agreed in principle to the new system while submitting it to guarantees against favouritism. The officers claimed that this arrangement was broken by Primo de Rivera. Whatever the merits of the case may be they were led to prepare a rebellion which the president nipped in the bud by abolishing the artillery corps by decree (September). Though an amnesty restored all but a handful of them to their posts the incident left behind much ill feeling within the country and between the artillery officers and the Government.

The fact is that the Government has not tackled the chief problem of the Spanish State—the reorganization of the army on an objective basis and its insertion within the framework of a civil society. The army is still mostly a nest of posts for the sons of the middle classes and an instrument of political bullying. In the 1925 reconstruction budget amounting to 3,747,000,000 pesetas no less than 1,508,000,000 were devoted to army and navy expenses (barracks 140,000,000, aviation 160,000,000, naval bases 187,000,000). Yet expenses in Morocco began to diminish after the surrender of Abd-el Krim and the Spanish zone was thoroughly pacified and disarmed by the new high commissioner, General Sanjurjo. A decree establishing an income tax was prepared in Dec. 1926, and is gradually working its way into the country's finances. A successful funding of a short-term debt (5,225,000,000 pesetas) led to a voluntary exchange of nearly all the outstanding Treasury bonds for long-term scrip, a trifling residue being refunded at par.

1927.—On Jan. 10, 1927, a sensational discovery was made in France when Señor Maciá, a Catalan separatist, an ex-major in the Spanish army, tried to invade Catalonia with a small band of armed men. The matter was more discussed in France than in Spain owing to its ramifications in Italy, some of Señor Maciá's accomplices being prominent Italian figures. The Government began to put into shape its plans for an assembly. For the rest of the year the country was able to follow—through the chinks in the censorship—the game of pull and push over the new-fangled pseudo-parliamentary creation of General Primo de Rivera. The strong man of the cabinet, General Anido, was understood to be against it; the king, threatened by the leader of the Conservatives, Señor Sánchez Guerra, with an open break if he consented to such a dispossession of the *cortes*, demurred. Finally the decree was signed and the king himself opened the assembly on Oct. 10, while Sánchez Guerra went into voluntary exile. The assembly is a purely advisory organization, all the members of which are appointed by the Government, and as such it has raised no interest. The president had solicited the collaboration of numerous intellectuals and of the Socialist Party but in the nature of things he was bound to meet with refusal in both these quarters and the assembly is as mediocre in its personnel as it is in its organization and work. True political events occur outside. The president had an interview with Sir Austen Chamberlain in Majorca (Oct. 1927). In this month also the king was able to visit Morocco, now entirely pacified. The Tangier negotiations with France, led finally, if not to the satisfaction of the Spanish claim, at least to a number of French concessions which put the position of Spanish safety in her zone on a slightly better basis than before (*see* TANGIER). These events paved the way for a change in Spain's attitude towards the League. Invited by the president of the League Council to reconsider her position (March 1928), Spain announced her willingness to remain within the fold of the League, handsomely trusting the League itself with the task of fixing her status on its Council. The situation thus reached a condition of stable equilibrium.

The president more than once announced his intention now to retire, now to remain in office for an indefinite number of years. The best successes of the Government have been reaped in the financial field where, owing to a period of peace, the admirable vitality of the country responded with added wealth and a budget was finally balanced, at least so far as could be ascertained under the existing system. In 1927 there was an increase of 80,000,000 pesetas over the previous year's receipts. The estimates for 1928 reasonably provided for a balanced budget; but in spite of such financial successes having for their background an economic situation on the whole prosperous, the political situation was far from steady. Though the censorship prevented not only the spreading of unfavourable news but particularly the possibility of any movement of opinion gathering momentum and reaching the field of political action, numerous incidents revealed the vitality of the opposition. Now and then an outspoken speech was heavily—though never cruelly—repressed, as in the case of Professor Asua of Madrid university, whose unjustified punishment led to a unanimous protest from the Faculty of Law of the University of Madrid and to a strike of students. The dictator, despite his evident good will and his successes in more than one field of government, has been the prisoner of his political inexperience. By gagging the nation he has deprived himself of adversaries, but by the same stroke he has deprived himself and the Crown of any alternatives. (S. DE M.)

BIBLIOGRAPHY.—*Sources.* The minute and increasingly critical study which has been made, especially in the last 25 years, of the sources of Spanish history (collections of documents and bibliography) has rendered most of the earlier collections almost valueless. Even from the point of view of the correctness of texts, some of these older collections have been in a large measure surpassed by more modern ones, among which the following may be recommended:

Bibliographical Guides.—B. Sánchez Alonso, *Fuentes de la historia española e hispano-americana* (1919, 2nd ed. 1927); R. Ballester, *Bibliografía de la historia de España* (Gerona 1921), *Las fuentes narrativas de la historia de España durante la Edad Media 417–1474* (Palma de Mallorca, 1908), and *Las fuentes narrativas de la historia de España durante la Edad Moderna*, Part 1 (Valladolid 1927); R. Foulché-Delbosc and L. Barrau-Dihigo, *Manuel de l'Hispanisant*, 2 vols. (New York 1920–25); Hispanic Society of America, *Bibliographie Hispanique*, 7 vols. (New York, 1905–17).

As regards modern historians and confining ourselves, as the nature of this note requires, to general works, the first was J. F. de Masdeu, *Historia critica de España y de la cultura española*, 20 vols. (1783–1805). After him came D. Modesto Lafuente y Zamalloa, whose work, the *Historia general de España*, 30 vols. (1850–67) was for half a century the most widely read and consulted, but has now been superseded by more modern works. An edition of his work in 25 vols. continued by J. Valera, A. Borrego and A. Pirala was published at Barcelona (1877–90).

At the beginning of the 20th century the *Historia de España y de la civilización española*, by R. Altamira y Crevea, 4 vols. (Barcelona, 1900–11, 4th ed., 1928) to a large extent superseded that of Lafuente because it embodies the results of recent research and also because it presents the most complete picture of Spanish civilization so far published and comprises the first selected bibliographical guide. The *Historia* stops at the year 1808, but its continuation will be found in the *Historia de la civilización española* by the same author (1928 edition in his *Obras completas*, Historical Series vol. iv.). Another work which treats the subject from a different point of view and is accompanied by a modern and selected bibliography is the *Epitome de la Historia de España*, also by Señor Altamira (1927). *See* also A. Ballesteros y Beretta, *Historia de España, su influencia en la Historia universal*, 4 vols. published (Barcelona, 1919, etc.), with an abundant bibliography; S. Aguado, *Manual de historia de España*, 2 vols. (Bilbao, 1927–28), which takes into account the most recent researches and contains a well arranged and critical bibliography. The *Historia general de España, escrita por individuos de la Real Academia de la Historia*, the publication of which was begun in 1892, has remained incomplete. Its various volumes, by a great variety of authors, are very unequal in quality and it is based on no general plan. Modern writers have also published fairly complete works on the separate history of the old divisions of Spain. The best hitherto published are those concerning Catalonia.

For the most recent period see *El Año Político* published yearly by Fernando Soldevilla; *El Anuario Financiero* published yearly by Emilio Riu; A. N. Young, *Spanish Finance and Trade* (1920); Count Romanones *El Ejército y la Política* (1921) and *Las Responsabilidades del Antiguo Régimen* (1924); F. de León y Castillo *Mis Tiempos* (1921); Francisco Cambó *En Torno del Fascismo Italiano* (1925); G. Maura Gamazo *Historia critica del reinado de Don Alfonso XIII.* (1925).

Of works by non-Spanish authors the best are those of Martin A. S. Hume, *Spain, its Greatness and Decay, 1479–1788* (1898), *Modern Spain, 1788–1898* ("Story of the Nations" Series, 1899) and *The Spanish people* (1901); Butler Clarke *Modern Spain, 1815–1898* (1906).

R. Bigelow Merriman, *The Rise of the Spanish Empire in the Old World and in the New*, 2 vols. (New York 1918), and *Reflexiones acerca del imperio español* (in the Bulletin of the Academy of History 1923). Good summaries of Spanish history year by year are published in the *Annual Register*. On the political history of the 19th century *see* also the Spanish chapters in A Stern, *Geschichte Europas seit 1815 bis 1871*, 10 vols. (Stuttgart, 1913–24).

SPAIN, BANK OF. The Banco de España, a successor to the Nuevo Banco Español de San Fernando, and the Banco de Isabel II., was raised to the category of the National Bank of Spain on March 19, 1874, by Don Jose Echegaray, then Minister of Finance. It was granted the exclusive privilege of issuing notes

Its capital, at that time 57,000,000 pesetas, was 177,000,000 pesetas on Dec. 29, 1921 In Dec. 1928 the reserves stood at 65,000,000 pesetas.

The fiduciary issue is regulated by the law of Dec. 29, 1921, which stipulates that up to a total circulation of 4,000,000,000 pesetas, the metallic reserves shall be 45%, of which, at least, 40% must be in gold Above 4,000,000,000 and up to a total maximum of 6,000,000,000 the metallic reserve shall be 60%, at least 50% being gold

As a consideration for privilege of note-issue, the Bank has to perform, free of charge, many services to the Treasury, and in addition to the ordinary taxes payable by all banks, the Treasury obtains from the Bank of Spain a percentage of the profits, varying from 10% to 50% according to the dividend. The Bank has 64 branches, 4 foreign agencies and nearly 6,000 correspondents in Spain. (A. Va)

SPAIN, CODES OF. (For mediaeval codes, *see* Fuero; Germanic Laws) The codes in force at the present time cover a considerable part of the legislation of Spain

They are. (1) The *Código fundamental, i e*, the Constitution of the State of 1876, which was preceded by the Constitution of Cadiz of 1812, and that of 1869. (2) The *Código civil*, comprising the law on status, rights and duties of persons (primarily Spaniards) considered as active members of society from birth to death. It came into force on May 1, 1889, and in the same year was applied to Cuba, Puerto Rico and the Philippine islands. As in the Code Napoleon, the Roman concepts were followed. The code in fact carried out the directions of the *Ley de Bases* of May 11, 1888 (3) The *Código de comercio* of 1885 which came into force on Jan 1, 1886, following the Code of 1829, was framed on the model of the French code of commerce with improvements taken from French jurisprudence and the previous local laws of Spain, such as the *Novisima Recopilacion* and the Ordinances of Bilbao. (4) The *Código de enjuiciamiento civil* (civil procedure) of Feb. 3, 1881 (5) The *Código de enjuiciamiento criminal* of Dec 22, 1872 (6) The *Código penal* of 1870 (7) The *Ley Hipotecaria* (mortgage law) of 1870. These have all been modified by subsequent legislation.

SPALATIN, GEORGE, the name taken by George Burkhardt (1484–1545), an important figure in the history of the Reformation, who was born on Jan. 17, 1484, at Spalt (whence he assumed the name Spalatinus), near Nuremberg, where his father was a tanner. He went to school at Nuremberg, and afterwards to the university of Erfurt, where he took his bachelor's degree in 1499. There Nikolaus Marschalk, the most influential professor, made Spalatin his amanuensis and took him to the new university of Wittenberg in 1502. In 1505 Spalatin returned to Erfurt to study jurisprudence, and was welcomed by the little band of German humanists of whom Mutianus was chief. He became a teacher in the monastery at Georgenthal, and in 1508 he was ordained priest by Bishop Johann von Laasphe, who had ordained Luther In 1509 Mutianus recommended him to Frederick III. the Wise, the elector of Saxony, who made him tutor to his nephew, the future elector, John Frederick. The elector sent him to Wittenberg in 1511 and procured for him a canon's stall in Altenburg. He managed all the elector's correspondence.

Spalatin's letters to Luther have been lost, but Luther's answers remain, and are extremely interesting. Spalatin read Luther's writings to the elector, and translated for his benefit those in Latin into German. He would have dissuaded Luther again and again from publishing books or engaging in overt acts against the papacy, but when the thing was done none was so ready to translate the book or to justify the act.

On the death of Frederick the Wise in 1525 Spalatin no longer lived at the Saxon court. But he attended the imperial diets, and was the constant and valued adviser of the electors, John and John Frederick. During the later portion of his life, from 1526 onwards, he was chiefly engaged in the visitation of churches and schools in electoral Saxony, reporting on the confiscation and application of ecclesiastical revenues and he was asked to undertake the same work for Albertine Saxony He was also permanent visitor of Wittenberg University. He died on Jan. 26, 1545, at Altenburg

His writings include· *Annales reformationis*, edited by E. S. Cyprian (Leipzig, 1718); and "Das Leben und die Zeitgeschichte Friedrichs des Weisen," published in *Georg Spalatins Historischer Nachlass und Briefe*, edited by C. G. Neudecker and L Preller (Jena, 1851). A list of them may be found in A Seelheim's *George Spalatin als sachs Historiographer* (1876). There is no good life of Spalatin, nor can there be until his letters have been collected and edited, a work still to be done There is an excellent article on Spalatin, by T. Kolde, in Herzog-Hauck, *Realencyklopadie*, Bd xviii (1906).

SPALATO or **SPALATRO:** *see* Split or Spljet.

SPALDING, ALBERT (1888–), American violinist, was born at Chicago (Ill), on Aug 15, 1888 At seven, he commenced his musical studies under Ulpiano Chiti in Florence, continuing them with Juan Buitrago in New York and Lefort in Paris Spalding's début was made in 1905 in Paris, where in 1906 he appeared again with Patti His first American appearance was with the New York Symphony Orchestra in 1908. In 1917 he joined the U.S. Aviation Corps, and served as liaison officer with the Italian command He played at La Scala, Milan, in 1919 His compositions include many works for the violin, a string quartet in E minor and an orchestral work entitled *Alabama*.

SPALDING, a market town in Lincolnshire. England Pop. of urban district (1921) 10,703. The parish church of St. Mary and St. Nicholas was built in 1284 and is of peculiar construction, having four aisles to the nave. It is mainly Decorated in style The adjoining lady chapel was built in 1315

Although there are no traces of settlement at Spalding (*Spaltnige*) before late Saxon times there was probably a village here before Thorold the sheriff founded his cell of Crowland Abbey in 1051. In Domesday Book the manor is said to belong to Ivo de Taillebois, who possessed a market there worth 40s.

SPALLANZANI, LAZARO (1729–1799), Italian man of science, was born at Scandiano in Modena on Jan. 10, 1729. At the age of fifteen he was sent to the Jesuit college at Reggio di Modena, but soon went to the university of Bologna, where his kinswoman, Laura Bassi, was professor of physics, and it is to her influence that his scientific impulse has been usually attributed. He was professor at Reggio, Modena and, under Maria Theresa, at Pavia, where he enriched the museum by the collections from journeys along the shores of the Mediterranean. In 1785 he was invited to Padua, but his sovereign doubled his salary and allowed him leave of absence for a visit to Turkey, where he made many observations. His integrity in the management of the museum was suspected, but an investigation cleared his honour. In 1788 he visited Vesuvius and Sicily, and embodied his researches in *Viaggi alle due Sicilie ed in alcune parti dell' Apennino* (1792).

His main discoveries were in the field of physiology: he wrote papers on respiration, on the senses of bats, etc., while he made experiments (1768) to disprove the occurrence of spontaneous generation, showing that animalcules did not develop in vegetable infusions which had been boiled and were kept in properly closed vessels. His great work is the *Dissertationi de fisica animale e vegetale* (2 vols , 1780). Here he first interpreted the process of digestion He also carried out researches on fertilization in animals (1780). He died at Pavia on Feb. 12, 1799.

SPANDAU, a suburb of Berlin, Germany. Pop. (1925) 110,-459. Spandau is one of the oldest places in the Altmark, and received civic rights in 1232. It afterwards became a favourite residence of the Hohenzollern electors of Brandenburg, and was fortified in 1577–83. In 1635 it surrendered to the Swedes, and in 1806 to the French. A short investment in 1813 restored it to Prussia Spandau was one of the chief garrison towns of the old German

Empire and contained the Imperial war treasure.

SPANDRIL, SPANDREL, in architecture, a space between any arch or arch-like form and the horizontal moulding or beam above it; also, in an arcade, the wall surface between two adjacent arches and any horizontal member above them.

SPANGENBERG, AUGUST GOTTLIEB (1704–1792), German Moravian bishop, Count Zinzendorf's successor, was born on July 15, 1704, at Klettenberg, on the south of the Harz Mountains, where his father, Georg Spangenberg, was court preacher and ecclesiastical inspector of the countship of Hohenstein. He was a student of law at Jena when he met Count Zinzendorf in 1728; in 1730 he visited the Moravian colony at Herrnhut. A "collegium pastorale practicum" for the care of the sick and poor was in consequence founded by him at Jena, which the authorities at once broke up as a "Zinzendorfian institution." His free lectures in Jena led to an invitation from Gotthilf Francke to the post of assistant professor of theology and superintendent of schools connected with his orphanage at Halle. He started work there in September 1732. But differences between the Pietists of Halle and himself soon became apparent. Spangenberg's participation in private observances of the Lord's Supper and his intimate connection with Count Zinzendorf brought matters to a crisis. He was offered by the senate of the theological faculty of Halle the alternative of doing penance before God, submitting to his superiors, and separating himself from Zinzendorf, or leaving the matter to the decision of the king, unless he preferred to "leave Halle quietly." The case came before the king, and, on April 8, 1733, Spangenberg was conducted by the military outside the gates of Halle. At first he went to Jena, but then to Herrnhut and found amongst the Moravians his life-work.

For the first thirty years (1733–62) his work was mainly devoted to the superintendence and organization of the extensive missionary enterprises of the body in Germany, England, Denmark, Holland, Surinam, Georgia and elsewhere. It was on an island off Savannah that Spangenberg startled John Wesley with his questions and profoundly influenced his future career. One special endeavour of Spangenberg in Pennsylvania was to bring over the scattered Schwenkfeldians to his faith. In 1741–42 he was in England collecting for his mission and obtaining the sanction of the archbishop of Canterbury. During the second half of this missionary period of his life he superintended as bishop the churches of Pennsylvania, defended the Moravian colonies against the Indians at the time of war between France and England, became the apologist of his body against the attacks of the Lutherans and the Pietists, and did much to moderate the mystical extravagances of Zinzendorf, with which his simple, practical and healthy nature was out of sympathy. The second thirty years of his work (1762–92) were devoted to the consolidation of the German Moravian Church. Zinzendorf's death (1760) had left room and need for his labours at home. At Herrnhut there were conflicting tendencies, doctrinal and practical extravagances, and the organization of the brethren was very defective. In 1777 Spangenberg was commissioned to draw up an *idea fidei fratrum,* or compendium of the Christian faith of the United Brethren, which became the accepted declaration of the Moravian belief. As compared with Zinzendorf's own writings, this book exhibits the finer balance and greater moderation of Spangenberg's nature. In his last years Spangenberg devoted special attention to education. He died at Berthelsdorf, on Sept. 18, 1792. In addition to the *Idea fidei fratrum,* Spangenberg wrote, besides other apologetic books, a *Declaration über die seither gegen uns ausgegangenen Beschuldigungen sonderlich die Person unseres Ordinarius (Zinzendorf) betreffend* (Leipzig, 1751), an *Apologetische Schlussschrift* (1752), *Leben des Grafen Zinzendorf* (1772–75); and his hymns are well known beyond the Moravian circle.

Ledderhose, *Das Leben Spangenbergs* (Heidelberg, 1846); Otto Frick, *Beiträge zur Lebensgeschichte A. G. Spangenbergs* (Halle, 1884); Gerhard Reichel's article in Herzog-Hauck's *Realencyklopädie* (ed. 1906), *s.v.* "Spangenberg"; the article by Ledderhose, in the *Allgemeine deutsche Biographie;* also MORAVIAN BRETHREN.

SPANISH-AMERICAN ARCHITECTURE. A brief study of architecture in Spanish-America must include a glance at the monumental and impressive architecture of the Mayas made up of receding terraced pyramids flanked with stairways and surmounted by temples of delicate proportions, of pure and refined design, with richly carved ornament decorating their surfaces. In Chichen Itzá the temples and buildings, 15 to 300 ft. high, square or rectangular in plan, were built of limestone, with walls, bases, cornices, doors and windows, typically Maya corbelled arches and rich ornament with sculptural carving. In the valley of Teotihuacan, about 20 m. from Mexico City, the Toltecs built two pyramids of imposing height and grandeur: one dedicated to the sun and the other to the moon. The former is larger than that of Mycherinus in Egypt. In Teotihuacan the structures are symmetrically laid along the main axis of the city called the Street of the Dead. The outstanding characteristics in the buildings and in the decoration are the use of straight lines, geometric figures, balance of masses, repetition of the same colours and the conventionalized design of plants and animals. The base of the "Ciudadela," the citadel, was 1,300 ft. on the side.

Spanish Colonization.—The outstanding and dominating feature of all architectural work in Spanish-America during the 16th, 17th and 18th centuries is the number, quality and character of the religious buildings that rose from the fertile land conquered by the Spaniards. At first the influence of the Italian Renaissance (*see* RENAISSANCE ARCHITECTURE) is evident. Then, gradually a fusion of the European arts, especially the Spanish and Italian Baroque, with the technique and the sentiment of the natives takes place. Finally, in the 18th century—and more so in Mexico than elsewhere—there springs the Ultra-Baroque of Spanish-America.

In Peru and Bolivia the native art, which had grown free from all exotic influence and which was unknown to Spain, was undoubtedly a fully developed art that, in spite of persecution and almost total destruction at the hands of the conquerors, had enough vitality left to rise again to influence the architecture and decorative arts of the Spaniards, and to leave in the architectural works of these centuries a trace of the lives and very souls of the natives.

This is also true of Mexico, whose architecture has very marked plastic and constructive characteristics which distinguish it from its Italian and Spanish inspirations, and which give it individuality in its arbitrary and flighty but effective ornamentation based on polychromic work. In Mexico, native architecture did not influence the colonial religious architecture; on the other hand, decorative sculpture and carving, among the most vigorous expressions of the aboriginal art shown in the native motives, did.

Monks of the Franciscan Order arrived in New Spain in 1523, of the Dominican Order in 1526, and the Augustines in 1533. The first type of construction used by the missionaries for their churches, in 1564, is that of the basilica (*q.v.*). The principal part of the convent is the church, and the church's exterior has the aspect of a fortress. This combination of temple and fortress in one building is a characteristic of 16th century religious architecture in Mexico. Religious buildings in Mexico may be divided into five types: (1) primitive churches as provisional temples; (2) the basilica type; (3) open chapels; (4) great fortified churches with single nave and no crossing, Romanic buttressing, Gothic vaulting and Renaissance or Baroque ornamentation in the portals; (5) cathedrals. The Augustines excelled the Franciscans in magnificence. The perfect type of Augustine churches of the middle of the 16th century is the church and convent of St. Augustine Acolman (1539), which had a single nave, no tower, fine frescoes, a beautiful cloister and a Plateresque (*q.v.*) portal that is the most notable example of this style in America. The Franciscans oriented their buildings from east to west. The convent of San Francisco in Mexico City was a monument of unusual grandeur and the most remarkable example of its type, covering originally an area of 33,000 square feet. The Dominicans were less sumptuous than the Augustines, but more so than the Franciscans in their buildings, and they tended to make their façades after the severe and sober Herrerian style of the Escorial.

Climax and Later Developments.—From the beginning of

the 17th century the prosperity of Spanish-America became so great that a wave of religious building swept over it. The 18th century found a complete religious unity and the power and wealth of the church reached an unsurpassed splendour, propitious to a great manifestation of the arts. The climax of all Spanish-American Colonial religious architecture, as far as magnitude and excellence are concerned, is reached when the cathedrals of the 17th century were built. Mexico alone has 35 cathedrals. The first great cathedral of America was that of Santo Domingo, built in 1514 The first one in New Spain was that of Mérida in Yucatán The cathedral of Puebla was completed in 1649 That of Mexico City represents the work of three centuries—the maximum personal effort of Spanish colonial art Its first stone was laid in 1563; it was dedicated in 1667 and completed in June 1813 It is undoubtedly the most remarkable monument that Spanish-American architecture produced In all small cities the church had its atrium (*q v.*), which served not only for religious purposes, but as a centre of concentration and defence. The outside defensive wall of the atrium became later an ornamental motif. A great part of the social life of the community, including dances and processions, took place in these centres. The parish church and its atrium represent the most interesting factor of Mexican collective life for 300 years. In three centuries of Spanish domination nearly 15,000 religious buildings were built in Mexico alone, and of these 8,000 in the 18th century. There are more than 18,000 cupolas in Mexico

The Ultra-Baroque of Spanish-America has rhythmic symmetry, exuberance of decoration, pictorial beauty and vigorous, plastic sentiment coupled with clever and artistic use of polychromic effects Besides these elements, the co-operation between the monks and the native labourers, masons, carvers and painters, their intuition and skilful use of building materials, and their spirit of improvisation to satisfy the requirements of construction as they presented themselves, made them successful in their search for effects in chiaroscuro through carving, or pictorial through the use of mass, outline and colour

In the 19th century Spanish-American architecture underwent a period of stagnation and decline because of political activities and unrest It is characterized by the works of European architects, principally French and Italian, which unquestionably affect the architecture of the period. The early 20th century records an initial movement toward the utilization of Spanish colonial types and motifs, chiefly in the solution of housing problems, which may lead to something worth while, provided there is a closer understanding of the changes that have taken place in the development of labour, industry, transportation and city planning, and a closer co-operation between architects, sculptors, painters and workers. Finally, the universal influence of the Exposition of Decorative Arts in Paris in 1925 has reached Spanish-America and its architecture shows once more the ill effects of hybrid imported architecture lacking the expression of the lives and needs of its people.

SPANISH-AMERICAN LITERATURE. For more than 300 years after its discovery Hispanic America was culturally as well as politically an Iberian colony. The *conquistadores* and the missionaries who accompanied them wrote the first Hispanic-American literature in the letters and reports which they sent back to Spain and Portugal telling of their victories with sword and cross. Longer accounts of the conquest like the *Sumario de la natural y general historia de las Indias* (1526) by Gonzalo Hernández de Oviedo y Valdés (1478–1557) and *La conquista de México y de la nueva España* (1552) by Francisco López de Gomara (1511–77?) soon followed The oppressed Indians found a champion in Fray Bartolomé de las Casas (1474–1566), whose *Brevísima relación de la destrucción de las Indias* appeared in 1552, but no one of their own blood rose to tell their story until the Inca, Garcilaso de la Vega (1540–1616), published his *Comentarios reales* (Pt I. 1609, Pt II 1616) and Fernando de Alva Ixtlilxochitl (1568–1648) his *Historia Chichimeca* more than a century after the invasion The colonizing missionaries, notably Padre José de Anchieta (1530–97), in Brazil, also produced grammars and lexicons of the Indian languages, as well as sermons and hymns

Before the end of the 16th century Mexico and Lima had become centres of intellectual activity. A printing press was set up in Mexico in 1539 and charters for a university were granted both cities in 1551 The extent to which letters were cultivated at the viceregal courts may be inferred from the fact that in a contest held at Mexico in 1585 more than 300 poets took part In colonial poetry, as in that of Europe, Ariosto's influence was dominant throughout the latter half of the century, but the epic, *Arauco domado* (Lima, 1594) by the Chilean Pedro de Oña (b. *c.* 1560) and the long descriptive poem, *Grandeza mexicana* (Mexico, 1604) by Bernardo de Balbuena (1568–1627), first bishop of Porto Rico, was constructed on native American themes.

The cult of Góngora, which in the following century superseded that of the Italians, called forth the first important piece of literary criticism in America, the *Apologético en favor de D Luis de Góngora* (Lima, 1694) by Juan de Espinosa Medrano, as well as the lyrics and prose selections of the anthology, *Ramillete de varias flores poéticas* (1675), collected by Jacinto de Evia (b. 1636), the *Música do parnaso* of Manoel Botelho de Oliveira (1636–1711) and the poems of Gregorio de Mattos Guerra (1637–92) While the Mexican-born Juan Ruíz de Alarcón (*c* 1580–1639)—generally counted among the great dramatists of Spain—is comparatively free from the affectations of this school, the mystical poems of his compatriot, Sor Juana Inés de la Cruz (1651–95), plainly show its influence

In the barren 18th century, except for the epic on national themes, represented in Mexico by the *Hernandia* (1755) of Francisco Ruíz de León and in Brazil by José Basilio da Gamma's *Uruguay* (1769) and José de Santa Rita Durão's *Caramuru* (1781), only the long Latin georgic, *Rusticatio mexicana*, by the Guatemalan Jesuit, Rafael Landívar (1731–93), the bucolic poems of the Mexican Manuel de Navarrete (1768–1809) and the writings of the group of scientists at Bogotá led by José Celestino Mutis (1732–1808) and Francisco José Caldas (1741–1816) deserve mention From this group of Colombian scientists came some of the first martyrs of Spanish-American independence. In Colombia, too, were first printed translations of the prohibited political pamphlets of the French Revolution These were disseminated throughout the colonies and together with the writings of men like José Joaquín de Lizardi (1774–1827), who criticized Spanish misrule in his journal, *El pensador mexicano*, and in *El periquillo sarniento*, the first real American novel, encouraged the colonists to throw off the Spanish yoke

In all parts of Hispanic-America the revolutionary victories called forth patriotic verse *La victoria de Junín. Canto a Bolívar* by José Joaquín Olmedo (1784–1847), of Ecuador, was the most successful of these occasional poems Among the other distinguished poets who wrote in the cause of liberty were José María Heredia (1803–39) of Cuba, best known for his *Himno del desterrado* and his ode to Niagara, José Fernández Madrid (1784–1830) and Luis Vargas Tejado (1803–29) of Colombia, Juan Cruz Varela (1794–1839) of Argentina, José Bonifacio de Andrade e Silva (1763–1838) of Brazil, and Andrés Bello (1781–1865) of Venezuela. Bello, who was to become later one of Spanish America's greatest scholars, is, however, not remembered for his political verse but for his *Silva a la agricultura de la zona tórrida.*

At the close of the revolutionary period the poets, imbued with a hatred of all things Spanish, turned for their inspiration to aboriginal themes. In "La cautiva" (*Rimas*, 1837) the Argentine

Esteban Echeverría (1805–51) wrote the first significant poem of the pampas, and in *A conspiração dos Tamoyos* (1834) the Brazilian Domingos José Gonçalves de Magalhães (1811–82) extolled the rebel Indians. Through the works of these men, who had studied in Paris, French romanticism was introduced into America. It was carried from Argentina to Uruguay and Chile by political refugees who fled the tyranny of Rosas, among them Juan María Gutiérrez (1809–78), compiler of the anthology *América poética,* and José Mármol (1818–81), author of *El peregrino,* a South American *Childe Harold,* and of the famous political novel *Amalia* (1851). In its later phases the movement is represented in Argentina by Olegario Victor Andrade (1838–83), author of *Atlántida* and the greatest poet of the republic. The type of romanticism which reached other sections of Latin America came directly from Spain. In Mexico, Ignacio Rodríguez Galván (1816–42) and Fernando Calderón y Beltrán (1809–45), like their models Espronceda and Zorrilla, were both lyric poets and dramatists. The poetry of José Joaquin de Pesado (1801–61), author of *Las Aztecas,* and of Manuel María Flores (1840–85) and some of the work of the Colombian, José Eusebio Caro (1817–53), is romantic in tone. Although the romantic period is richest in lyric poetry, it also produced three important novels: Mármol's *Amalia,* the *María* of Jorge Isaacs (1837–95) and the *Moreninha* of the Brazilian Joaquím Manoel de Macedo (1820–82).

Of especial significance in the development of Hispanic-American literature is the appearance in the latter half of the 19th century of an indigenous phenomenon peculiar to the Argentine, the so-called "Gaucho poetry." The gaucho's life as literary material had been used in the dialogues of *Chano y Contreras* by Bartolomé Hidalgo (1787–?) and in Domingo Faustino Sarmiento's *Facundo* (1845). Now it received epic treatment in the popular idiom in Estanislao del Campo's *Fausto* (1866) and José Hernández's *Martín Fierro* (1872).

Another original literary *genre,* which appeared at about the same time in Perú, is the creation of one man, Ricardo Palma (1833–1919), who in his famous *Tradiciones peruanas* (first series 1872) elevated the historical anecdote to the realm of art.

Two Modern Movements.—Within more recent times two forces have come to direct the course of Hispanic-American letters. The first of these, the "modernista" movement, has been concerned chiefly with problems of literary form. It calls for the enrichment of poetry by new rhythms and new words. Its spokesman was Rubén Darío (1867–1916), a native of Nicaragua, but a resident of most of the countries of South America at some time of his life. Among its adherents have been counted poets from almost all the Latin American republics. The most eminent of them are the Colombian, José Asunción Silva (1860–96), the Uruguayan, Julio Herrera y Reissig (1875–1910), the Mexicans, Manuel Gutiérrez Nájera (1859–95), whose poems even before the publication of Darío's epoch-making *Azul* (1888) had been modernistic in spirit, Salvador Díaz Mirón (1855–1928), and Amado Nervo (1870–1918), the Cuban, Julián del Casal (1863–93), and the Bolivian, Ricardo Jaimes Freyre. Most of the present generation of lyric poets are still under the influence of the "modernista" tradition.

The second movement, "Americanismo" or "Criollismo," is concerned with the subject matter of literature. In its broadest aspects it is a gospel of nationalism and racial solidarity. Its prophet was the Uruguayan, José Enrique Rodó (1872–1917), the "Latin Emerson," who wrote his message in the essay *Ariel* (1899). It was introduced into poetry by José Santos Chocano (1867–) and into the novel by Manuel Romero García (1865–) in his *Peonía* (1890). It has found expression in the dramas of Florencio Sánchez (1875–1910) and the lesser playwrights of the Argentine *teatro criollo* (creole theatre). The greater number of its followers are writers of prose fiction. Among the novelists Gonzalo Picón Febres (b. 1860), Carlos Reyles (b. 1870), Ricardo Güiraldes (1886–1927) and Enrique Larreta (b. 1875) write of ranch life; Martín Aldao (b. 1879) and Manuel Gálvaz (b. 1882) of urban society; Rufino Blanco Fombona (b. 1874), Manuel Diaz Rodríguez (1868–1927), Lorenzo Marroquín (d. 1918) and Roberto Payró (1867–1928), of national or local politics. The short-story writers, Luis Urbaneja Achelpohl, Manuel Ugarte (b. 1875), Javier de Viana (1872–1926), Horacio Quiroga (b. 1879) and Coelho Netto (b. 1864), show a preference for rural settings and local colour.

With the recent economic and industrial development of the Hispanic-American States the different nationalities have become more individualized and their cultural life more distinct. In the economically more advanced countries prose fiction is replacing poetry as the favourite vehicle of expression. The future literary history of Spanish America will be more and more a history of the literature of the individual countries.

(E. H. H.)

SPANISH-AMERICAN WAR OF 1898. On Feb. 15, 1898, the U.S. battleship "Maine" was destroyed in Havana harbour by an explosion, with a loss of 266 lives. An American board of inquiry made an extensive examination of the wreck, and reported to the navy department on March 21 that the explosion was caused by an exterior mine, the principal reason for this decision being the upheaval of the ship's bottom. On April 20 President McKinley approved a resolution demanding the withdrawal of Spain from Cuba and setting noon of April 23 as the latest date for a reply. Before this could be delivered by the American minister in Madrid, the Spanish Government sent him his passports. On the 22nd the president declared a blockade of Cuban ports; on the 24th the Spanish Government declared war; and on the 25th the United States Congress declared that war had existed since the 21st.

The joint resolution of Congress of April 20 had declared that relinquishment by Spain of authority in Cuba was the object of American action; the struggle thus naturally centred about the island and all operations were thus at hand. The regular United States army, the only available force until war was declared and a volunteer force was authorized, had been assembled at Tampa, New Orleans and Chickamauga; but until the control of the sea was decided, the army could not prudently be moved across the Strait of Florida. The Spanish fleet under Cervera, which had left the Cape Verde islands for the West Indies, was the real objective of the navy, and had to be settled with before any military action could be undertaken. Accordingly Rear-Admiral Sampson left Key West early on April 22, and began the blockade of Havana and the north coast of Cuba. His North Atlantic squadron of 28 vessels of all kinds, of which the armoured cruiser "New York" (flag), the battleships "Iowa" and "Indiana," and the monitors "Puritan," "Terror" and "Amphitrite" were the most important, and which included six torpedo-boats, was increased to 124 vessels by July 1.

Battle of Manila Bay.—In the Pacific, the American squadron—the protected cruisers "Olympia" (flagship of Commodore George Dewey), "Baltimore," "Raleigh" and "Boston," the small unprotected cruiser "Concord," the gunboat "Petrel," the armed revenue cutter "Hugh M'Culloch," with a purchased collier "Nanshan" and a purchased supply ship "Zafiro"—left Hongkong at the request of the governor and went to Mirs bay, some miles east on the Chinese coast. Ordered (April 25) to begin operations, particularly against the Spanish fleet, which he was directed to capture or destroy, Dewey left Mirs bay on the 27th, and arrived off Luzon, in the Philippines, on April 30. The Spanish admiral Montojo anchored to the eastward of the spit on which are the village and arsenal of Cavite, in a general east and west line, keeping his broadside to the northward. His force consisted of the "Reina Cristina," the "Castilla" (an old wooden steamer which had to be towed), the "Isla de Cuba" and "Isla de Luzon" (protected cruisers of 1,050 tons), the "Don Juan de Austria" and the "Don Antonio de Ulloa" (gunboats of about 1,150 tons) and

the "Marques del Duero" (of 500 tons).

Dewey passed into the Boca Grande, paying no attention to rumours of torpedoes, and at midnight passed El Fraile. When he sighted the Spanish squadron to the southward he stood down in column with the "Olympia," "Baltimore," "Raleigh," "Petrel," "Concord" and "Boston" at 400-yd. intervals. When within 5,000 yds. he ported his helm, and at 5.41 A M opened fire He stood westwards along the Spanish line, using his port batteries, turned to starboard and stood back, gradually decreasing his distance to 2,000 yds. At 7.35 Dewey withdrew and gave his men breakfast Before he re-engaged at 11.16 the "Cristina" and "Castilla" had broken into flames, so that the remainder of the action consisted in silencing the Cavite batteries and completing the destruction of the smaller Spanish ships. The victory was complete All the Spanish ships were sunk or destroyed. The injury done the American ships was practically nil. The Spanish lost 167 killed and 214 wounded, out of a total of 1,875. The Americans had 7 slightly wounded out of 1,748 men in action. Dewey took possession of Cavite, and awaited the arrival of a land force to capture Manila.

Santiago.—Cervera had left the Cape Verde islands on April 29 with four armoured cruisers, the "Almirante Oquendo," "Infanta Maria Teresa" and "Vizcaya" (sister ships of 7,000 tons) and the "Cristobal Colon" (same size; differently equipped) and three torpedo-boat destroyers. On hearing (May 1) of Cervera's departure, Sampson went east to San Juan, Porto Rico, with the armoured cruiser "New York," the battleships "Iowa" and "Indiana," the cruisers "Montgomery" and "Detroit," and one torpedo-boat. He reached San Juan on the 12th. Cervera's was not present, and Sampson at once started back for Havana. Cervera reached Santiago de Cuba early on the 19th without being sighted *en route*. It was not until the end of the month that the American fleet was assembled before the harbour. An attempt was made to sink the collier "Merrimac" in the entrance channel, which was less than 200 ft. broad in parts available for ships. The preparations for a quick sinking were chiefly carried out by naval constructor Richmond P. Hobson, who went in, in the early morning of June 3, with a crew of seven men. The steering-gear was disabled by a shell, and the ship drifted too far and was sunk in a broad part of the channel where it did not block the egress of Cervera's squadron.

On June 6 the batteries at the entrance were bombarded and their weakness was ascertained Sampson thereupon placed, every evening, a battleship close in, with a searchlight turned on the channel, making it impossible for the Spanish squadron to escape by night. The port of Guantánamo, 40 m. east of Santiago, was occupied and was used thereafter às a base and coaling station.

The Land Campaign.—When war was declared the total military forces of the United States consisted of 27,822 regulars and 114,602 militia. An act of April 22 had authorized the president to call upon the States and Territories for men in proportion to their population. A first call was made for 125,000 men, and a month later a second call for 75,000. On April 26 large additions to the regular army were sanctioned for the war. The quotas were filled with extraordinary rapidity, and in May 124,776 had volunteered. The troops were concentrated chiefly at Chickamauga, Ga , at Camp Alger, Va , and at Tampa, Fla , which was selected as the point for the embarcation of the expeditionary force for Cuba, and where Major-General W. R. Shafter was in command. After the arrival of Cervera at Santiago, the blockade of his squadron and the request (June 7) of Admiral Sampson to send a land force for co-operation, the troops embarked on June 7 and 8, but a start was not made until the 14th. On the 29th the fleet of 32 transports arrived off Santiago. The whole force consisted of about 17,000 officers and men, 16 light field guns, a train of heavier pieces, and some 200 vehicles. On the 22nd–25th the army was landed at Daiquiri, 18 m. east of Santiago, on a rough coast with scarcely any shelter from the sea; after the first day Siboney, 7 m. nearer Santiago, was used as well as Daiquiri. With the exception of three volunteer regiments (the 1st Volunteer Cavalry, known as the Rough Riders, of which Theodore Roosevelt was lieutenant-colonel; the 2nd Massachusetts and the 71st New York Volunteers), these troops were composed almost wholly of regulars, most of whom had served on the plains against the Indians Soon afterwards more volunteers arrived.

No opposition was made to the landing. The American troops (commanded by Major-General Joseph Wheeler until the 29th, when General Shafter landed) pushed forward, but the advance was slow and a week elapsed before Shafter was ready to fight a battle in front of Santiago Here the defenders, under General Arsenio Linares, held two positions, the hill of San Juan, barring the direct road to Santiago, and the village of El Caney, to the northward of the American position at El Pozo. The plan of attack on July 1 was Shafter's, but owing to illness the actual command was exercised by the subordinate generals, Joseph Wheeler, H W. Lawton and J F Kent General Lawton's division was to attack and capture El Caney, and thence move against the flank and rear of the defenders of San Juan, which would then be attacked in front by Kent and Wheeler from El Pozo. But Lawton for nine hours was checked by the garrison of El Caney, in spite of his great superiority in numbers (4,500 to 520); at 3 P M. the final assault on El Caney was successfully delivered by General A. R Chaffee's brigade. Only about 100 of the Spanish garrison escaped to Santiago; about 320 were killed or wounded, including General Vara del Rey, who was killed. In the meantime Wheeler and Kent had an equally stubborn contest opposite San Juan hill, where, in the absence of the assistance of Lawton the battle soon became a purely frontal-fire fight, and the rifles of the firing line had to prepare the attack unaided The strong position of the Spaniards, gallantly defended by about 700 men, held out until 12 30, when the whole line of the assailants suddenly advanced, without orders, and carried the crest of the Spanish position On the American side over 1,500 men out of 15,000 engaged, including several of the senior officers, were killed or wounded. On the Spanish side, out of the small numbers engaged, over 50% were out of action. Linares himself was severely wounded.

Though victorious, the American army was in danger: after great fatigue under a tropical sun by day, the time spared at night from digging trenches was spent on a rain-soaked ground; the soldiers' blankets and heavy clothing had been cast aside; and there was insufficient food. Brisk firing was continued on July 2 and 3, with a considerable number of casualties to the Americans On the morning of the 3rd a demand was sent to the Spanish commander to surrender, with the alternative of a bombardment of the city to begin on the 4th.

Naval Battle of Santiago.—On the morning of July 3 Sampson, in his flagship the "New York," left the fleet to confer with General Shafter at Siboney with regard to combined operations at the harbour entrance. At 9 31, when he had gone about 5 m., the "Maria Teresa" was seen coming out. The ships in front of the port were the yacht "Gloucester," the battleships "Indiana," "Oregon," "Iowa" and "Texas," the armoured cruiser "Brooklyn" and yacht "Vixen " The "Iowa" hoisted the signal "Enemy coming out." All at once stood in toward the Spanish ships, which were standing westwards along shore, and began a heavy fire. The "Maria Teresa" (flagship) was followed at 800-yd. intervals by the "Vizcaya," "Colon" and "Oquendo " They were firing vigorously, but most of their projectiles went far beyond the American ships. The "Brooklyn" (flag of Commodore Schley, the senior officer present) made a turn to starboard, which seems to have caused the "Texas" to stop and back, and to have given the "Colon" the opportunity of passing almost unscathed. The "Maria Teresa" and "Oquendo" had taken fire almost at once, and were run ashore about 6½ m. west of Santiago, burning fiercely. The "Vizcaya" and "Colon" were still standing westwards. The "New York," Sampson's flagship, had passed, and stood on signalling the "Iowa" and "Indiana" to go back and watch the port, lest an attack be made on the American transports. The "Vizcaya" hauled down her colours off Aserraderos, 15 nautical miles west of Santiago, and was there run ashore burning. The "Iowa" was ordered to stop and rescue her men, and the "Oregon," "Brooklyn" and "Texas" (and behind them the flagship) settled down to the chase of the "Colon," some 6 m. ahead. She was, however,

slacking her speed, and at 12.40 the "Oregon" opened with her 13-in. guns at a range of 9,000 yds., as did also the "Brooklyn," with her 8-in. When the "Oregon" had fired five shells, the "Colon" hauled down her colours, and was beached at the mouth of the Rio Turquino. The whole Spanish fleet was destroyed; Admiral Cervera was taken prisoner. Over 500 Spaniards were killed or wounded, and the survivors (except a few who escaped to Santiago) were prisoners. On the American side only one man was killed and ten were wounded, and no ship received serious injury.

After the naval victory combined operations were arranged for attacking the batteries of the harbour, but little more fighting occurred, and eventually a preliminary agreement was signed on the 15th, and the besiegers entered Santiago on the 17th. The exposure of the campaign had begun to tell in the sickness of the Americans: yellow fever had broken out to some extent; and no less than 50% were attacked by the milder forms of malarial fever. The army, indeed, was so weakened by illness that the general officers united in urging its removal from Cuba.

Fall of Manila.—On May 7 a telegram had been received from Dewey at Manila: "I control bay completely, and can take city at any time, but I have not sufficient men to hold." Major-General Wesley Merritt, to whom was assigned the command of the troops for the Philippines, first requested a force of 14,000, and afterwards asked for 20,000 men. On May 25 the first troops, 2,491 in number, under Brigadier-General T. M. Anderson, sailed from San Francisco. On June 20 possession was taken of the island of Guam, and on June 30 the ships arrived in Manila bay. A second detachment of troops, 3,586 in number, under Brigadier-General F. V. Greene arrived on July 17; on July 25 General Merritt, who had been appointed governor-general, arrived; and on the 31st the five transports with which he had left San Francisco arrived with 4,847 men, making nearly 11,000 men at Manila, with 5,000 more on the way. General Merritt moved his forces from Cavite, and established an entrenched line within a thousand yards of the Spanish position at Manila. On Aug. 7, a joint note from Dewey and Merritt, announcing that bombardment might begin at any time after forty-eight hours, was sent to the Spanish captain-general, Fermin Jaudenes, who replied that he was surrounded by the insurgents, and that there was no place of refuge for the sick and for the women and children. A second joint note demanding surrender was declined by the Spanish commander. Preparations were made for an attack. There were 13,000 troops within the city fortifications, but with the strong fleet in front, and with the beleaguering force of Americans and insurgents ashore, resistance was hopeless. When the combined assault of army and navy was made on the 13th there was no great resistance, and a white flag was hoisted at 11 o'clock. The total loss of the Americans during the whole campaign was 20 killed, 105 wounded.

Porto Rico.—Immediately after the surrender of Santiago (July 17), preparations were made for the invasion of Porto Rico with 3,500 troops which had been sent as reinforcements to Santiago, but had not landed. They were largely reinforced and left Guantánamo, under General Miles, on July 21. The towns on the south side of the island were occupied, practically without resistance. The attitude of the population was exceedingly friendly, and opposition was not met until advance was begun northward. The troops were divided into four columns, advancing from Guanica around the western end of the island to Mayaguez; from Arroyo at the eastern end to meet the San Juan road at Cayey; from Ponce by the fine military road, 70 m., to San Juan; and the fourth column by way of Adjuntas and Utuado, midway of the island. The various movements involved several skirmishes. On Aug. 12 operations were begun by the "Newark" and other vessels against Manzanillo. But during the night news arrived of the signing of the peace protocol on the 12th, and of an armistice.

The total American loss was—in the navy, 1 officer, 17 men killed; in the army, 29 officers, 440 men. The health of the American fleet was kept remarkably. Its average strength during the 114 days of hostilities was 26,102; the deaths from disease during this time were 56, or at the rate of 7 per 1,000 per year. As nearly the whole of the service was in the tropics, and in the summer or wet season, this is a convincing proof of the efficiency in sanitary administration. The army did not fare so well, losing by disease during May, June, July and August, 67 officers and 1,872 men out of an average total of 227,494. Its larger proportion of illness must of course be ascribed, in part, to its greater hardships. The lack of proper preparation by the war department and the ignorance and thoughtlessness of the volunteers were the principal reasons for the high death-rate in the army.

For the terms of the peace and the results of the war *see* UNITED STATES; PHILIPPINE ISLANDS; CUBA; PORTO RICO.

The literature of the Spanish-American War is voluminous. *See* the *War Notes* of the Office of Naval Intelligence, Washington, the appendix to the report of the Bureau of Navigation and reports of other Government departments for 1898. F. E. Chadwick, *The Spanish-American War* (2 vol., 1911) is the standard work. Good histories are H. C. Lodge, *The War with Spain* (1899), and H. W. Wilson, *The Downfall of Spain* (1900). *See* also W. A. M. Goode, *With Sampson through the War* (1899); J. Wheeler, *Santiago Campaign* (1899); Theodore Roosevelt, *The Rough Riders* (1899); C. D. Sigsbee, *Personal Narratives of the Battleship Maine* (1899); R. A. Alger, *Spanish-American War* (1900); Gomez Nuñez, *La Guerra hispano-americana* (1900); John D. Long, *The New American Navy* (2 vols., 1903); and George Dewey, *Autobiography* (1913).

SPANISH BROOM, a handsome shrub with long switch-like green, few-leaved or leafless branches and large yellow sweet-scented papilionaceous flowers. It is a member of the pea family (Leguminosae), and known botanically as *Spartium junceum.* It is a native of the Mediterranean region and the Canary Islands, and is often cultivated, especially in California where it blooms almost throughout the year. The whole plant, but especially the flower shoots and seeds, has a bitter taste and tonic and diuretic properties, and was formerly used medicinally. The fibres of the young stems were used in making nets, carpets, mats, baskets, etc.; the flowers yield a yellow dye.

SPANISH LANGUAGE AND LITERATURE. The Iberian Peninsula was, up to the fifteenth century, linguistically more diversified than at present. The chief languages and dialects were Castilian, Asturian-Leonese, Navarro-Aragonese, Mirandese, Catalan and Galician-Portuguese (Northern and Southern Dialects). The Mirandese dialect acquired at an early date Galician-Portuguese characteristics; Catalan is a Provençal dialect; Castilian absorbed the Asturian-Leonese and Navarro-Aragonese languages and in later years gave rise to a literature which was quantitatively and qualitatively the most important amongst Peninsular literatures. Its authority gradually extended beyond the geographical limits of Old and New Castile, even Catalan and Portuguese authors writing in *Castellano.* The Spanish-speaking world has between 80 and 90 million inhabitants (about twice as many as those speaking French and nearly three times as many as those speaking Italian). The Castilian language has become identified with Spanish (*Español*).

Spanish and Latin.—Romance languages in their morphology and syntax derive from *spoken* Latin, older than the *written* Latin of the classical writers and probably differing from it in its syntax, as the syntax of the Romance languages, which is more closely akin to that of High German or of modern Greek than to that of written Latin, tends to show. A definite Latin influence is the Spanish use of the Subjunctive. Generally speaking Spanish syntax is very elastic; thus the position of the subject is more variable than in French or even in English. The Peninsula began to be latinised at the end of the third century B.C., long before Gaul and Northern Italy. But our knowledge of spoken Latin is necessarily slight, and early latinisation alone does not account for the characteristics of Spanish, as compared to the other Romance languages.

The influence of pre-Roman Iberian languages is doubtful There remain, besides place-names, **vega** (open plain, mead), **nava** (plain surrounded by mountains) and the word **páramo** (deserted plain, moor) which appears on a votive altar, dedicated to Diana and discovered in Leon, in an inscription according to which Tullius offers Diana the antlers which he has hunted *in parami aequore*—on the desert plain.

The Phonetics of Modern Spanish.—The Spanish vowels are very close to the standard vowels of the phonetic scheme. The following points should be noticed:

1. The "a" is distinctly velar before back vowels like *o* and *u*, before *l*, and any velar consonant such as *k*, *x*, *g*, etc. This is particularly noticeable in **caja** = κάχɐ.

2. The difference between open and close *e* (ϵ, e) is generally much less marked than in French for example, the most extreme cases of difference being seen in **cielo** and **tierra**. The closed *e* is more open than the French **é** in *été*.

3 The same remarks apply to the open and closed *o* (ɔ, o), the closed *o* being also more open than the French *ô* in *tôt*.

4. The closed vowels occur as a rule in open syllables and the open vowels in closed syllables or in contact with a double *r*, but the closed *e* also occurs in a syllable closed by *s* or a nasal, as in **cesta** and **atento**.

5. The semi-vowels in such words as **ley, soy** are preceded by an open vowel

6. The semi-vowel *u* velarises the preceding *a* in such words as **causa**.

There is a general tendency in Spanish to combine groups of vowels into one syllable, so that we find tripthongs in which the first vowel (*u* or *i*) has become a semi-consonant and the last (*u* or *i*) semi-vowel: **averiguéis, cambiáis**. This blending of vowels to form one syllable occurs also when the vowels are not contained in one word, thus **Italiaha intervenidoen la guerra europea**. This, as spoken by a Spaniard at a normal pace, would contain twelve syllables, the last two vowels of "**europea**" forming two separate syllables.

The general smooth fluency of Spanish speech is seen in the historical development of consonants which have come down by oral tradition, and in the treatment of words derived from foreign sources or learned words of Latin origin which often contain difficult consonant groups: Lat. *nata*>**nada** (ð) Lat. participle ending in *-atu*>**-ado**.

The tendency towards assimilation is very noticeable: **Ascensión** in which *c* often yields to influence of *s*, **apto** in which *p* becomes a mere implosive under influence of *t* In the case of learned words in modern speech, the pronunciation is a compromise between smoothness and an effort at correctness: **acción** (agθjɔn).

Accent of intensity. This accent or stress is particularly important in Spanish and requires greater muscular tension in its production than is usual in English words, because the unstressed vowels are pronounced in Spanish with great care, as, though slightly weakened, they never lose their identity. In general the syllable which bore the accent in Latin retains it in Spanish

The Articles.—In spoken Latin the noun was preceded by the demonstrative pronoun *ille* (*illum*, *illu*) and the indefinite pronoun *unus* (*una*). From them derive the definite articles **el, la, lo**, plural **los, las**, and the indefinite articles **uno, una**.

Nouns.—The inflexions so characteristic of *written* Latin were never used to the same extent in the *spoken* langauge. In Spanish, there are strictly speaking no declensions though traces survive in a few cases such as that of the personal pronoun **yo, me, mi; el, le; nosotros, nos.** In spoken Latin the prepositions indicated cases, *e.g.*, Plautus says *hunc ad carnificem dabo*. In modern Spanish the preposition **de** corresponds to the genitive, **para** and **a** to the dative, **a** or the absence of preposition to the accusative, o to the vocative and **con, en, por, sin, sobre, trás** to the ablative. But the remains of the classical declensions are seen in the grouping of the noun, the form of which in the great majority of cases is traceable to that of the accusative case in singular or plural forms.

The nouns belonging to the Latin third declension appear in Spanish as words ending in *e* or in a consonant, the plural ending in *es*:

S. *patre-*>**padre**	Pl. *patres*>**padres**
S. *leone-*>**león**	Pl. *leones*>**leones**

This group also absorbed words from other declensions, especially the fifth as the accusative endings were similar. The gender of nouns derived from the third declension is generally the same as in Latin, the neuter nouns being distributed between the two groups according to no settled rule, thus for instance the Latin *sal* which appears in French as masculine (**le sel**) is feminine in Spanish (**la sal**).

Adjectives and Adverbs.—Adjectives follow the principles described in the development of the noun. The neuter has disappeared (except in the abstract use of the adjective as a noun: **lo usual es**—it is the custom), and therefore the Latin three and two endings are reduced to two and one respectively: **inglés** (-a), **triste.** There is however a tendency to supply a feminine form as in **Superiora** (Mother Superior), noticeable also in adjectives ending in **on, ol;** *e g*, the Spanish-speaking Jews of the Balkan peninsula still say **la lengua español** instead of the modern feminine **española;** on the other hand the same Jews have added feminine endings to **ilustre ilustra** and **joven, jóvena** (a young girl) while Peninsular Spanish preserves the old usage in one ending *Comparison*: The classical comparative and superlative are rare in Spanish (**bueno, mejor, óptimo**) and are expressed by the use of the adverb *magis*>**más** in the case of the comparative and by the comparative preceded by the article to render the superlative: **tonto, más tonto, el (la, lo) más tonto.** The superlative in *-issimus*>**-isimo** is a latinism which was felt to be un-Spanish by the old writers like King Alfonso X (d 1284), and, although accepted to-day, it has a pedantic and rhetorical flavour.

Regular adverbial usage differs from the Latin: (a) The adverb is normally formed by the substantive *mente* appended to the feminine form of the adjective: **tonto, tonta, tontamente.** (b) A great number of Latin adverbs were, however, preserved: *adhuc* >**aun**, *quando*>**cuando**, *magis*>**más**, *sic*>**si**; also combinations of prepositions and adverbs: *de-intro*>**dentro**, *intuncce*>**entonces**, *de-ex-post*>**después**, *ad-illic*>**alli**, etc.

Pronouns.—The Pronouns include Personal Pronouns (Nominative: **yo, tu, el, ella;** Plur. **nosotros, vosotros, ellos;** Dative: **le, lo, les, los;** Accusative: **me, te, se, nos, os;** Emphatic forms used after prepositions: **él, mí, tí;** Note **conmigo, contigo, consigo**) with the closely connected Possessive or Adjective Pronouns (**mi, tu, su; mio, tuyo, suyo**); the Demonstrative Pronouns (**este, ese, aquel**) amongst which, historically speaking, should be classed the third person of the Personal Pronouns and the article, and finally the almost identical relatives and interrogatives (**que, quien, el cual; ¿qué? ¿quien? ¿cuál?**).

Numerals.—The cardinal numerals are: **uno (-a), dos, trés, cuatro, cinco, seis, siete, ocho, nueve, diéz; veinte** (20), **treinta** (30), **cuarenta** (40), **cincuenta** (50), **sesenta** (60), **setenta** (70), **ochenta** (80), **noventa** (90), **cien, ciento,** (100), **doscientos** (200), **quinientos** (500) **setecientos** (700), **novecientos** (900), **mil** (1,000). The ordinals are **primero (a), segundo (a), tercero (a), cuarto (a), quinto (a), sexto (a), séptimo (a), octavo (a), noveno (a), décimo (a).** The ordinals are learned in form and are not used in ordinary conversation beyond ten.

Verbs.—In Spanish the four Latin conjugations are reduced to three, the infinitive endings being **ar, er, ir,** that is to say that the second and third conjugations in ēre, ĕre have been amalgamated. The only traces of original differences are seen in the strong preterites and past participles of irregular verbs. The Present Indicative and Subjunctive of regular verbs are very close to the Latin originals:

Pres. Ind.	**canto, cantas, canta, cantamos, cantáis, cantan**
Subj.	**cante, cantes, cante, cantemos, cantéis, canten**
Pres. Ind.	**temo, temes, teme, tememos, teméis, temen**
Subj.	**tema, temas, tema, temamos, temáis, teman**
Pres. Ind.	**parto, partes, parte, partimos, partís, parten**
Subj.	**parta, partas, parta, partamos, partáis, partan**

SPANISH LITERATURE

Spanish literature falls into three divisions: Castilian, Catalan, Galician. Galician is included under Portuguese. It should not be forgotten, however, that Spain, in the two Senecas, Lucan, Martial and Quintilian—as also in Prudentius—made a considerable contribution to Latin literature; while the writings of Spanish Muslims and Jews, both in prose and verse, form an important branch of the literature of Arabic.

1. CASTILIAN LITERATURE

By the time of the Muslim invasion (711) the Latin spoken in the peninsula was already in process of transformation into a Romance *patois* which, from the few words that have come down to us (some of them preserved in jest by the Arabic-speaking conquerors), seems to have resembled the modern dialect of Galicia rather than that of Castile. The earliest documents date from the 10th century; while the revival of the study of Latin in northern Spain in the 11th century led to the neglect of the vulgar tongue by the learned, and the complete separation between the spoken and the written language. Castilian, *romance castellano,* became the official language for public documents under Ferdinand III. (1217–52) and Alfonso X. (1252–84).

Heroic Poetry, 1050–1250.—Castilian literature begins with the poem of the Cid (*Cantar de mio Cid*), an historical character named Rodrigo Díaz de Bivar (d. 1099) and usually known by his Arabic title, *Sid* (lord). The poem, as the brilliant researches of Menéndez Pidal have abundantly proved (*see* bibliography), dates from 1140; the only existing ms. is an imperfect copy made in 1307. It was first printed in 1779. The *Cantar de mio Cid* is a work of noble inspiration. Apart from all questions of originality—whether it owes more to French or to Germanic models, the poem is intensely Castilian in its directness of expression and unflinching realism. The assonant metre seems to be on the same principle as that of the other early Spanish epics which have partly survived—*Los siete infantes de Lara,* reconstructed by Menéndez Pidal from a prose chronicle in which it had been incorporated, and the *Roncesvalles* fragment, recently discovered in the cathedral at Pamplona. It is *versificación irregular;* that is, it depends not on the number of syllables (11–20) in the line, but on a system of "pointing," a regular number of accents or beats such as would naturally be made by a minstrel in the process of chanting. The frequent allusions in the chronicles to the narratives of the minstrels, or *juglares,* suggest that Castilian heroic poetry was far richer than the scarcity of mss. would lead us to believe. These poems were composed not only by minstrels, but also in monasteries in which a hero happened to be buried—a distinction which was considered worthy of advertisement. Thus the *Poema de Fernán González* (the first independent Count of Castile) is the work of a learned Benedictine in the monastery of San Pedro de Arlanza.

Berceo.—The same form was used for the religious and didactic poetry of the 13th century, the chief representative of which is Gonzalvo de Berceo (d. after 1246), the earliest Spanish poet whose name is known. Born at Berceo near Logroño at the end of the 12th century, he entered a Benedictine monastery in the neighbourhood of Calahorra, where he put into poetical form the lives of Spanish saints, the miracles of the Virgin Mary, and other devotional subjects; and his verse gives the impression of a child-like wonder which Spanish poetry was never able to recapture. Berceo called his poems *prosa, decir* or *dictado,* indicating that he intended them to be read or recited, and not sung like the *cantares;* yet he maintains the fiction that he is really a minstrel, singing in the language in which a man speaks to his neighbour and adds that his *prosa* should be worth a cup of good wine. The single-rhyme quatrain was also the form in which two other 13th century poems were written: *El Libro de Alixandre* (the mediaeval legend of Alexander) and *El Libro de Apolonio* (Apollonius of Tyre), both of considerable length and derived from French and Latin sources. To the 13th century also are assigned a life of *Santa Maria Egipciaca,* derived ultimately from a poem attributed to Robert Grosseteste, Bishop of Lincoln (d. 1253); an Adoration of the Magi (*Libro de los tres reyes de oriente*) of Provençal origin, and a fragment of a Debate between the Soul and the Body (*Disputa del alma y cuerpo*), closely related to an Anglo-Norman version of one of the mediaeval Latin poems, entitled *Rixa animi et corporis.*

In the earlier epic period the influences from abroad were predominantly French. The second period is one in which the chief foreign influence was Arabic. The gates of Oriental learning and story were opened to Spain and to the whole of Europe by the capture of Toledo (1085), which became a school of translation from oriental languages. As early as 1120 Petrus Alfonsi, a Spanish Jew who had become a convert to Christianity, introduced Indian fable into Spain with the famous collection of stories written in Latin and known as *Disciplina clericalis.* The Spanish translation of the "beast-fable" *Kalila and Dimna,* made directly from an Arabic text, dates from 1251; it is the first attempt at story-telling in the Spanish language. The romance of the Seven Sages (or *Sendebar*), under the title of *Libro de los engannos é asayamientos de las mujeres* (book of the wiles and deceptions of women), was translated in 1253, and other collections of Eastern stories followed.

Alfonso the Sage.—Alfonso X., *el Sabio* (the Sage), king of Castile and León (1252–84), may justly be called the father of Castilian prose. Under his patronage, and indeed under his editorship, a number of vast works were undertaken, including

the great legal code, *Las Siete partidas* (a mine of curious information on Spanish life and customs of the time); together with valuable compilations from Arabic sources, such as the *Libro de saber de astronomia*, the "Alfonsine Tables," the *Lapidario* and the *Libro de los juegos*—an illustrated book of games, including dice, draughts and several varieties of chess played on boards of different sizes. Alfonso X. was also the founder of Spanish historiography in the vulgar tongue. The *Crónica general*, begun under his direction, gave rise to a whole series of chronicles in the vernacular. Alfonso X was also responsible for one of the greatest collections of mediaeval poetry and music; the illuminated mss. of the *Cántigas de Santa Maria*, but as the language employed in them is Galician Portuguese, they have been considered under the literature of Portugal

The period of translation and compilation from oriental and other sources represented by the school of Alfonso X. was succeeded by a brilliant period of original work, in the prose of the Infante Don Juan Manuel (1282–1349?) and the poetry of the archpriest of Hita (d. before 1351) Both had learnt from Eastern story not only how to employ fables for teaching moral lessons, but also how to set them in a suitable frame. In Don Juan Manuel's *Conde Lucanor* the count asks the advice of his councillor, Patronio, on certain questions of life and government, and Patronio replies in each case by telling a story to illustrate the point. Many of the 50 stories are admirably told, and are the first works of Spanish fiction which give evidence of an individual style. The moral tone is uniformly high, and the author is clearly conscious that he has a public duty to perform by writing

The Archpriest of Hita.—Juan Ruiz, archpriest of Hita, is a man of the people, with no sense of personal obligation to society and still less with any apparent religious vocation. Yet he is a true poet, and an artist to the tips of his fingers His book of verse, generally known as *Libro de buen amor* ("the book of true love"—*buen amor*, as contrasted with earthly love, *loco amor*), is, in form, a satirical autobiography in which he tells with disarming candour the story of his love-affairs. There is no possible chance of an allegorical interpretation. The love that leads the archpriest is earthly love, though he protests in lyrics of passionate sincerity his devotion to the Virgin Mary. Not all his desires end in fulfilment; but some of the ladies, *e g*, Doña Endrina, are vividly and enchantingly portrayed, and the go-between, Trotaconventos (an ancestor of La Celestina), is the first great character in Spanish literature Though the form of the work is to a certain extent oriental (a frame-work on which numerous apologues and fables are hung), the archpriest has also availed himself of forms and subjects from France. He employs every metre known to him in a masterly fashion.

Contemporary with the *Libro de buen amor*, or perhaps, earlier, is the *Poema de Yuçuf*, a version of the legend of Joseph written in Aragonese dialect in single-rhymed quatrains. Its peculiarity is that though the words are Spanish, they are written in Arabic; and the entire poem is derived from the Koran and other Islamic sources. It shows how the Spanish Muslims clung to their handwriting, even after they had lost their language and their religion.

Arthurian Romance.—14th century Spain had already begun to be acquainted with the romances of chivalry; and the oldest known Spanish example, *El Caballero Cifar*, was probably composed near the beginning of the 14th century. The "matter of Britain," also, was known to Spain even in the time of Don Juan Manuel (who, in a book on the chase, mentions the fact that hawks in his possession were called Lancelot and Gawaine), although the narratives now in existence belong almost exclusively to the 15th and 16th centuries. In spite of the numerous versions and continuations of *Amadis* which followed printing, the romances of chivalry were always importations from abroad; and nothing is further from the unromantic, realistic Spanish spirit than the two distinguishing features of the Round Table: sentimental devotion and supernatural adventure. The chivalry which Cervantes satirized was not Spanish at all.

The 15th century shows the first effects in Spain of literary influence from Italy; it is the period of transition from the middle ages to the Renaissance. There was a growing sense of privacy, a craving for refinement on the part of a society still savage and blood-thirsty at heart and always on the verge of civil war. The artificiality and exaggerated good manners of the poetry of this epoch renders it dull and unattractive to modern readers; but it should never be forgotten that it was an attempt, on the part of the finer spirits among the great lords and the poets in their service, to soften the asperities and barbarities of daily life, and to provide collections of verse which could be recited or sung on festal occasions Examples of such collections are the *Cancionero de Baena* made for Juan II. of Castile *ca.* 1445, and the *Cancionero de Stúñiga* compiled for use at the Neapolitan court of Alfonso V. of Aragon (1416–58). while, after the invention of printing, the tradition was continued in the *Cancionero general* (1511) and the shameless *Cancionero de obras de burlas* (1519).

Marqués de Santillana.—Early in the 15th century, however, longer didactic poems began to be written under the influence of Dante. The *Divina Commedia* was introduced into Spain by Francisco Imperial, the son of a Genoese who had settled at Seville; the works of Petrarch and Boccaccio began to be read, and the Greek and Latin classics to be translated. Juan de Mena was the author of a fantastic allegorical poem *El Laberinto de Fortuna* (1444?); but the great name in the literary history of the century is that of Don Iñigo López de Mendoza, first Marqués de Santillana (1398–1458). Santillana, like Don Juan Manuel, was not only a soldier and a statesman, but also a scholar and a gentleman, with a keen sense of public duty and of the responsibilities placed upon him by his position in the world, both as a man and as a writer. The most illuminating of his works is the letter addressed to the Constable of Portugal, on the nature of poetry—the earliest piece of literary criticism in Spanish—in which the writer draws upon his reading in Italian, French, Provençal, Catalan, Galician and Portuguese, and upon such Greek and Latin classics as he had been able to obtain in translation. He was a great collector of manuscripts (many of which are still to be found in the Biblioteca Nacional at Madrid), and his Florentine bookseller bore witness to his intimate knowledge of the Italian tongue. He was the first to introduce the Italian sonnet into Spain, and the first to paraphrase Horace But he is best remembered for his shorter *canciones* and *decires*, and above all for his delightfully musical *serranillas*, which give the impression of having come into his mind in the first instance during the long rides to which his active life as a great feudal lord led him. He also was the first to notice how rich in proverbial sayings the speech of the Spanish country-people can be, and he made a collection of "The wise saws (*refranes*) of old women who sit by the fire."

In the confusion and decadence of the following reign, that of Enrique IV. (1454–74), literature found expression in biting satire or in resignation and the contemplation of death. This was the attitude which produced one of the most justly famous of all Spanish poems, the *Coplas* of Jorge Manrique (d. 1478) on the death of his father.

In prose, the 15th century saw the first appearance of Spanish books of travel, as represented by the journey to Samarkand (1403–06) of an ambassador of Enrique III, Ruy González de Clavijo; and the travels in Europe (1435–39) of Pero Tafur. In biography, Fernán Pérez de Guzmán with his *Generaciones y Semblanzas* (part of a larger work entitled, *Mar de historias*) and Hernando del Pulgar with his *Claros varones de Castilla*, left admirable portraits of eminent Castilians of their time

The Spanish Humanists.—The Renaissance may be said to begin in Spain with the accession of Ferdinand and Isabella in 1474, the year in which the first Spanish printing press was set up at Valencia. The revival of learning led in two opposite directions; it brought a taste for the antiquities of classical tradition and also for the antiquities of Spanish tradition, as preserved in the *romances* (ballads), *refranes* (proverbs), as well as in the chronicles and earlier prose works. New Spanish prose in a classical mould was printed side by side with the stories

of Don Juan Manuel (1575) and the travels of González de Clavijo (1582); while in the poetry of the period, the new forms introduced from Italy by Boscán (d. 1542) and Garcilaso de la Vega (d. 1536) became acclimatized at the same time that the traditional Spanish forms of *romance* and *villancico* began to attract the attention of men of letters. The first Spanish humanists were also the first grammarians and lexicographers of the Spanish language; the *Universal vocabulario en latin y romance* of Alonso de Palencia (1490) and Nebrija's *Arte de la lengua castellana* (1492) are the first of their kind. Other Spanish humanists of distinction, who were also disciples of Erasmus, were Luis Vives, and Juan de Valdés (author of the admirable *Diálogo de la lengua*) both belonging to the reign of Charles V. (1517–56); while Juan del Mal Lara, Arias Montano, Francisco Sánchez "el Brocense" and Luis de León lived under the increasing persecution of thought in the reign of Philip II. (Recent attempts to belittle or justify the repressive zeal of the Inquisition should be received with caution.) Many of the best brains and noblest minds in Spain at the time were followers of Erasmus, who, by his personal example and the example of his writings (printed in Spanish from 1520 until their suppression after his death in 1536), was the guiding light of the Spanish renaissance.

The Romancero.—*Romances* are defined by Menéndez Pidal as short epic-lyric poems sung to an instrument, either in choral dances, at festal gatherings or during work in common. They were first printed in *pliegos sueltos* (not as "broadsides," but as pamphlets), and then, about 1550, collected into the *Cancionero de Romances,* published at Antwerp. The older *romances* date from the century before, and one or two may go back even farther than that. Many of them are fragments of epic poems, remembered and sung by the people themselves after the decay of minstrelsy in the second half of the 14th century, and the metre (16-syllable verses with uniform assonance) suggests an instinctive attempt to systematize the irregular versification of the epics. Another group of *romances,* novelesque rather than heroic, employed a stanza-form more appropriate to lyric poems. The poetical value of many *romances* is heightened by their fragmentary condition. This is well shown by the famous *romance* of Count Arnaldos. The complete ballad has been collected from exiled Spanish Jews in Tangier, yet the curtailed version has transformed a ballad into an other-worldly poem of haunting beauty. This cutting-down of long *romances* by generations of singers has endowed them with a singular perfection of style; and those versions, worked out by some of the most cultured men of the time, are the versions in which the *romances* are now generally known.

The Stage.—Nowhere is the popularity of the *romances* better shown than in their capture of the public stage. The origin of drama in Spain is presumed to have been not very different from that in France and England. Direct evidence is lacking, between the *Auto de los reyes magos,* a 13th century fragment of a play on the three kings and the *Representación del nacimiento de nuestro Señor,* a 15th century nativity play by Gómez Manrique. There is, however, a constant tradition of religious performances in the vulgar tongue, supported by references in legal and other documents, and by the *Mystery of Elche,* still performed on Aug. 14 and 15. (*See* CATALAN LITERATURE.) The existence of a secular drama in the 13th century is proved by a passage in the *Siete partidas* of Alfonso X. By the end of the 15th century the difference was not so much between sacred and secular plays, as between plays in verse and plays in prose, and between the private stage and the public stage.

Among the earliest examples in verse are the *Representaciones* and *Eglogas* of Juan del Enzina, many of which were written for performance before the duke of Alba and end with lyrical *villancicos* set to music by the author himself. The *Cancionero* containing most of his works was printed in 1496. Among his Nativity, Passion and Resurrection plays, the *Auto del Repelón* stands in curious contrast, its subject being the relation between "town" and "gown" in the University of Salamanca. His shepherds and peasants have become comic characters, speaking a definite rustic dialect (*sayagués*) which afterwards became a dramatic convention. In imagination, plot, characterization, and a sense of the stage, he was surpassed by his Portuguese contemporary, Gil Vicente, 11 of whose 43 plays are written entirely in Spanish. His lyrics are the gems of Spanish poetry of the period; his vivid, plastic representation of allegory looks forward to Calderón. The *Barca da gloria* (a ship in which all the passengers are dead) suggests an English play of the 20th century, while the *Auto da sibilla Cassandra* has a psychological interest unsurpassed by any play of its period: the heroine refused to marry, believing herself destined to become the mother of God. Bartolomé de Torres Naharro, who settled at Naples, had a greater sense of the stage than Enzina, and more technique in the management of dialogue. He also had a sense of humour. While his *Comedia soldadesca* (1517) satirizes an army of occupation, his *Tinellaria* is the comedy of the servants' hall in the palace of a Roman cardinal, where the mixture of languages must have sounded irresistibly comic when brought on to the stage, however tiresome it may be to a modern reader. His *Aquilana* and *Calamita* (1520) look forward to the romantic, novelesque plays of Lope de Vega; *Seraphina* and *Imenea* foreshadowed the comedy of cloak and sword. Torres Naharro wrote for a private Italian stage and an audience of cardinals.

The public stage in Spain is first known from the works of Lope de Rueda (d. 1565; not to be confused with Lope de Vega), a famous travelling showman who had been inspired by the vivid acting of a company of Italian players, touring Spain with *Commedia dell' arte.* His longer plays (six in prose, three in verse) are mainly founded on Italian originals. His comic prose *pasos* (interludes performed during the pauses of other plays), though admirable as examples of the actual spoken Spanish of the period, lose the reason for their existence without the traditional and often obscene comic business and "gag" with which they must inevitably have been presented. Lope de Rueda was, in his turn, an inspiration to Cervantes, who afterwards described his simple staging and properties, and whose own Interludes (*entremeses*) whether in verse or prose, are masterpieces in the style. The prose theatre in Spain developed no further until the 18th century. The first dramatist to realize what might be made of the *Romancero* in the theatre (although he never used the actual metre of the *romances*) was Juan de la Cueva, whose plays were printed in 1583. With Lope de Vega and his followers, however, the *Romancero* was brought bodily on to the public stage, and in *Las Mocedades del Cid* (1618) of Guillén de Castro, ballad-characters from the cycle of the Cid's youth come on to the stage and recite the *romances* in which they occur. The plays of Cervantes belong to an earlier and, as he believed, a better tradition; had they been written in prose they might have received more of the attention which they deserve.

Fiction.—The masterpiece of the reign of Ferdinand and Isabella is a novel in dialogue form, the *Tragicomedia de Calisto y Melibea* generally known as the *Celestina.* The authorship is uncertain. First printed, it seems, in 1499, the *Celestina* ran through numerous editions in Spain and has been translated into most European languages (English, by James Mabbe 1631) while it has given rise to innumerable sequels and imitations. In conception, it is a tragedy worthy of Shakespeare, in execution admirable dialogue is one more example of the blending of the popular with the erudite. Like Shakespeare, the author of the *Celestina* has fully developed the personalities of even the minor characters; while the stark realism of the whole story, particularly in the surroundings of La Celestina herself, has had an influence on European literature which can hardly be exaggerated. Another work of fiction had a long line of successors and an English translation; the *Historia del Abencerrage y la hermosa Xarifa,* a tale of Moors and Christians by an unknown writer of the time of Ferdinand and Isabella, which eventually found its way into the *Diana* of Montemayor (d. 1561), the first Spanish example of the pastoral novel introduced from Italy. (J. B. T.)

Classic Age, 16th and 17th Centuries.—The golden age of Spanish literature belongs to the 16th and 17th centuries, extending approximately from 1550 to 1650. Previous to the reign of the Catholic sovereigns there exists, strictly speaking, only a Cas-

tilian literature, largely influenced by imitation first of France and then of Italy; the union of the two crowns of Aragon and Castile, and afterwards the advent of the house of Austria and the king of Spain's election as emperor, achieved the political unity of Spain and the unity of Spanish literature. After the death of Philip IV. (1665) the light went out; the nation, exhausted by wars and bad administration, produced nothing; it fell again under the influence of France

Poetry.—Lyric poetry, especially that of the more ambitious order, was generally inspired by the Italian masters. Juan Boscán, Garcilaso de la Vega and Diego Hurtado de Mendoza wrote *al itálico modo.* The defects of Boscán and Mendoza (such as certain faults of rhythmic accentuation) were corrected by their disciples Gutierre de Cetina, Gregorio Silvestre, Hernando de Acuña, by the poets of the so-called school of Seville, headed by Fernando de Herrera and also by those of the rival school of Salamanca, rendered famous mainly by the inspired poetry of Luis de León Against these innovators the poets, faithful to the old Castilian manner, the rhymers of *redondillas* and *romances,* held their own; under the direction of Cristóbal de Castillejo, they carried on a fierce war against the "Petrarchists." But by the last third of the 16th century the Italian school had triumphed.

Almost all the poets of the 16th and 17th centuries tried their powers in both kinds of versification. Thus Lope de Vega, first of all, who wrote *La Dragontea* (1598), *La Hermosura de Angélica* (1602), *La Jerusalem conquistada* (1609), in Italian verses and in octaves, composed his long narrative poem on Isidore, the patron of Madrid (1599), in *quintillas* of octosyllabic verse, not to mention a great number of *romances* The 17th century is characterized by a superabundance of lyric poetry. Góngora introduced into Castilian poetry the baroque style, characterized by sonorous diction, artificial arrangements of phrase and a system of inversions based on Latin syntax; but Góngora, a poet of really great powers, had begun with *romances* in which he found true poetic accents, ingenious ideas and felicitous expressions. Quevedo, much greater in prose than in verse, displays real power only in satire, epigram and parody. There is in some of his serious pieces the stuff of a Juvenal, and his satiric and burlesque *romances,* of which several are written in slang (*germanía*), are in their way little masterpieces Tasso's epic was inspired by *Gerusalemme;* when the author happens to have taken part in the events he narrates, it has a genuine historical interest. Alonso de Ercilla's *Araucana* was written less with a pen than with a pike. *La Gatomaquia* of Lope de Vega, and *La Moschea* of Villaviciosa (d. 1658) show witty invention.

Fiction.—The departments of imaginative literature in which the genius of the new Spanish nation revealed itself with most vigour and originality are the *novela* and the drama. By *novela* must be understood the novel of manners, called *picaresca* (from *pícaro,* a rogue or "picaroon") because of the social status of the heroes of those fictions; and this type of novel is a Spanish invention. The pastoral romance, on the other hand—the best-known examples of which are the *Diana* of Jorge de Montemayor, continued by Alonso Pérez and Gaspar Gil Polo, the *Galatea* of Cervantes, and the *Arcadia* of Lope de Vega—as well as the novel of adventure begun by Cervantes in his *Novelas exemplares,* and cultivated after him by a host of writers, is directly derived from Italy. The *Arcadia* of Sannazaro is the source of the *Diana* and of all its imitations, just as the Italian *novellieri* are the masters of most Spanish *novelistas* of the 17th century. The picaresque novel starts in the middle of the 16th century with the *Vida de Lazarillo de Tormes, sus fortunas y adversidades;* the impetus was given, and the success of *Lazarillo* was so great that imitators soon appeared. In 1599 Mateo Alemán published the first part of the adventures of another picaroon, Guzmán de Alfarache; before he could issue the sequel (1604) he was anticipated (1602) by an unscrupulous rival, whose continuation was on a lower plane. Quite unlike that of the *Lazarillo,* the style of Mateo Alemán is eloquent, full, with long and learned periods, sometimes diffuse. (*See* PICARESQUE NOVEL.)

By degrees the picaresque romance was combined with the novel of Italian origin and gave rise to a new type—half novel of manners, half romance of adventure—of which the characteristic example appears to be the *Marcos de Obregón* (1618) of Vicente Martínez Espinel, one of the best written works of the 17th century. To the same class belong almost all the novels of Alonso Jerónimo de Salas Barbadillo, Luiz Vélez de Guevara and Francisco Santos's popular pictures of life in Madrid, *Día y noche de Madrid* (1663), *Periquillo, el de las gallineras,* etc On the other hand, the novels of Tirso de Molina (*Los Cigarrales de Toledo,* 1624), Perez de Montalbán (*Para todos,* 1632), María de Zayas (*Novelas,* 1635–1647), are more in the manner of the *Novelas exemplares* of Cervantes, and consequently of the Italian type. Among the so-called historical romances may be mentioned the *Guerras civiles de Granada* (1595–1604) by Ginés Pérez de Hita, which describes the last years of the kingdom of Granada.

Don Quixote (1605–15), the masterpiece of Cervantes (*q v.*), is too great a work to be treated with others. It is the social romance of 16th and 17th century Spain The purpose was not to ridicule the books of chivalry, which were already out of fashion by his time, but to show by an example pushed to absurdity the danger of those prejudices of pure blood and nobler race with which three-fourths of the nation were imbued, and which, by the scorn of all useful labour which they involved, were destined to bring Spain to ruin. The lesson is all the more effective, as Cervantes's *hidalgo,* although ridiculous, wins our sympathy.

Drama of the 17th Century.—The stage in the 17th century in some measure took the place of the *romances* of the previous age; it is, as it were, the medium of all the memories, all the passions, and all the aspirations of the Spanish people Its style, being that of the popular poetry, made it accessible to the most illiterate classes, and gave it an immense range of subject. The Bible, the lives of the martyrs, national traditions, the chronicles of Castile and Aragon, foreign histories and novels, even the daily incidents of contemporary Spanish life, the escapades and nightly brawls of students, the gallantries of the Calle Mayor and the Prado of Madrid, balcony escalades, sword-thrusts and dagger-stabs, duels and murders, fathers befooled, jealous ladies, pilfering and cowardly valets, inquisitive and sprightly waiting-maids, sly and tricky peasants, fresh country girls—all are turned to dramatic account

The enormous mass of plays with which the literature of this period is inundated may be divided into two great classes—secular and religious; the latter may be subdivided into (1) the liturgical play, *i e*, the *auto* either *sacramental* or *al nacimiento,* and (2) the *comedia divina* or the *comedia de santos,* which has no liturgical element, and differs from a secular play only in the fact that the subject is religious and frequently, as one of the names indicates, derived from the biography of a saint In the secular drama, classification might be carried almost to any extent if the nature of the subject be taken as the criterion. It will be sufficient to distinguish the *comedia* (*i e*, any tragic or comic piece in three acts) according to the social types brought on the stage, the equipment of the actors, the artifices resorted to in the representation or the place of performance—public theatre or private stage. We have (1) the *comedia de capa y espada,* which represents everyday incident, the actors belonging to the middle class, simple *caballeros,* and consequently wearing the garb of ordinary town life, of which the chief items were the cloak and the sword; and (2) the *comedia de teatro* or *de ruido,* or again, *de tramoya* or *de aparencias* (*i e.,* the theatrical, spectacular or scenic play), which has kings and princes for its dramatis personae and makes a great display of mechanical devices, decorations and music Besides the *comedia,* the classic stage has also a series of little pieces subsidiary to the play proper: the *loa,* or prologue; the *entremés,* a kind of interlude which afterwards developed into the *sainete;* the *baile,* or ballet accompanied with singing; and the *zarzuela,* a sort of operetta thus named after the royal residence of La Zarzuela, where the kings of Spain had a theatre.

As to the dramatic poets of the golden age, it is hard to group them. All are more or less pupils or imitators of the great chief of the new school, Lope Felix de Vega Carpio, described as "monster of Nature." Among Lope's contemporaries only a few poets of Valencia—including Guillén de Castro, the author of the

Mocedades del Cid (from which Corneille derived his inspiration)—formed a small school, which could only win the applause of the public by copying as exactly as possible the manner of the great initiator. Lope's most incontestable merit is to have given the Spanish stage a range and scope of which it had not been previously thought capable, and of having taught his contemporaries to invent dramatic situations and to carry on a plot. It is true he produced little that is perfect: his prodigious fecundity and facility allowed him no time to mature his work; he wrote negligently what he considered to be good for the *vulgo.*

Lope's first pupils exaggerated some of his defects, but at the same time, each, according to his own taste, widened the scope of the *comedia.* Antonio Mira de Amescua and Luis Vélez de Guevara were successful, especially in tragic histories and *comedias divinas.* Gabriel Téllez, better known under the pseudonym of Tirso de Molina displayed no less talent in the comedy of contemporary manners than in historical drama. *El Burlador de Sevilla* (*Don Juan*) is reckoned his masterpiece; but he showed himself a much better dramatist in *El Vergonzoso en palacio, Don Gil de las Calzas Verdes* and *Marta la Piadosa.* Finally Juan Ruiz de Alarcón the most serious and most observant of Spanish dramatic poets, successfully achieved the comedy of character in *La Verdad sospechosa,* closely followed by Corneille in his *Menteur.* The second epoch of the classical drama is represented mainly by Pedro Calderón de la Barca, the Spanish dramatist who has obtained most celebrity abroad. Calderón more than any other writer made honour, or more correctly the point of honour, an essential motive in the conduct of his personages (e.g., *El Médico de su honra*); it is he also who made the *comedia de capa y espada* uniform even to monotony, and gave the comic "part" of the *gracioso* (confidential valet of the *caballero*) a rigidity which it never previously possessed. There is depth and poetry in Calderón, and a great sense of the stage. Two contemporaries were Francisco de Rojas Zorilla, author of the fine historic play *Del Rey abajo ninguno,* and Agustín Moreto, author of some pleasant comedies. Luis Quiñones de Benavente was a skilful writer of *entremeses.*

History.—A new manner of writing appears with the revival of learning; the purely objective style of the old chroniclers, accumulating one fact after another, without showing the logical connection or expressing any opinion on men or things, began to be thought puerile. An attempt was made to treat the history of Spain in the manner of Livy, Sallust and Tacitus, whose methods of narration were directly adopted. The 16th century, however, still presents certain chroniclers of the mediaeval type, with more erudition, precision and the promise of a critical faculty. *La Crónica general de España,* by Ambrosio de Morales; the *Compendio historial* of Estéban de Garibay; and the *Historia general de las Indias occidentales,* by Antonio de Herrera, are, so far as style is concerned, continuations of the last chronicles of Castile. Jerónimo de Zurita is emphatically a scholar; no one in the 16th century knew as he did how to turn to account documents and records for the purpose of completing and correcting the narratives of the ancient chronicles; his *Anales de la corona de Aragón* is a book of great value, written in a laboured style.

With Juan de Mariana history becomes a work of art. The *Historia de España* by the celebrated Jesuit, first written in Latin (1592) in the interest especially of foreigners, was afterwards rendered by its author into excellent Castilian; as a general survey of its history, well planned, well written and well thought out, Spain possesses nothing that can be compared with it. Among works of less extent, there are the *Guerra de Granada,* by Diego Hurtado de Mendoza (a history of the revolt of the Moors of the Alpujarras under Philip II.), written about 1572, immediately after the events, but not published till 1627; the narrative of the expedition of the Catalans in the Morea in the 14th century, by Francisco de Moncada (d. 1635); that of the revolt of the same Catalans during the reign of Philip IV., by Francisco Manuel de Mello, a Portuguese by birth; and that of the conquest of Mexico by Antonio de Solís.

The historians of the wars of Flanders, such as Carlos Coloma, Bernardino de Mendoza, Alonso Vázquez and Francisco Verdugo, are less refined, and more vivid. The accounts of transatlantic conquests are either by eyewitnesses, *e.g.,* Bernal Díaz del Castillo (1492–1581), one of the companions of Cortés, and Bartolomé de las Casas, the apostle of the Indians; or by official historiographers, such as Francisco López de Gómara, who wrote in Spain second hand.

Philosophy.—The Spanish thinkers of this epoch, whatever the school to which they belonged—scholastic, Platonic, Aristotelian or independent—wrote in Latin. Ascetic and mystical authors alone made use of the vulgar tongue for the readier diffusion of their doctrine among the illiterate, from whose ranks many of their disciples were recruited. Luis de Granada (1504–1588), Luis de León (1528–1598), Santa Teresa (1515–1582), Pedro Malón de Chaide and St. John of the Cross are the brighter lights of this class of writers. Some of their books, like the *Guía de pecadores* of Luis de Granada, the autobiography of St. Teresa, and Malón de Chaide's *Conversion of the Magdalen* (1588), have much influenced the development of mysticism in France. The Spanish mystics are not so remarkable for the depth or subtlety of their thoughts as for the intensity of the divine love with which they are inspired; many of them are masters of style, and some, like St. John of the Cross, have composed fluent devotional verse inspired by the *Song of Songs.* They profess practical ideas in the matter of morality. Nothing is more sensible, nothing less ecstatic, than the manual of domestic economy by Luis de León—*La Perfecta casada.*

Lay moralists are numerous in the 16th and 17th centuries. Some write long and heavy treatises on the art of governing, the education of princes, the duties of subjects, etc. But there is a kind of morality in which the Spaniard excels, namely, in social satire, which, under all its forms—dialogue and dream in the style of Lucian, epistle after the manner of Juvenal, or pamphlet—has produced several masterpieces and a host of ingenious, caustic and amusing compositions. Juan de Valdés (d. 1541), the most celebrated of the Spanish Protestants, led the way with his *Diálogo de Mercurio y Carón*—admirable in vigour.

The most eminent author in the department of social satire, as in those of literary and political satire, is Quevedo. Nothing escapes his scrutinizing spirit and pitiless irony. All the vices of contemporary society are remorselessly pilloried and cruelly dissected in his *Sueños* and other short works. This great satirist is a disciple of Seneca. His phrases are charged with a double meaning (*Conceptism*). This new school had its Boileau in Baltasar Gracián, who published his *Agudeza y arte de ingenio* (1642), in which all the subtleties of conceptism are reduced to an exact code.

Spanish thought as well as public spirit and all other forms of national activity began to decline towards the close of the 17th century. The advent of the house of Bourbon, and the increasing invasion of French influence in the domain of politics as well as in literature and science, frustrated the efforts of a few writers who had remained faithful to the pure Spanish tradition. The first symptoms, not of a revival, but of a certain resumption of intellectual production, appear in the department of linguistic study. In 1714 there was created, on the model of the French academies, La Real Academia Española, intended to maintain the purity of the language and to correct its abuses. This academy set itself at once to work, and in 1726 began the publication of its dictionary in six folio volumes, the best title of this association to the gratitude of men of letters. The *Gramática de la lengua castellana,* drawn up by the academy, did not appear till 1771.

Ignacio de Luzán, well read in the literatures of Italy and France, a disciple of Boileau and the French rhetoricians, yet not without some originality of his own, undertook in his *Poética* (1737) to expound to his fellow countrymen the rules of the new school, and, above all, the principle of the famous "unities" accepted by the French stage from Corneille's day onward. What Luzán had done for letters, Benito Feijóo, a Benedictine of good sense and great learning, did for the sciences. His *Teatro crítico* and *Cartas erúditas y, curiosas,* collections of dissertations in almost every department of human knowledge, introduced the Spaniards to the leading scientific discoveries of foreign countries,

and helped to deliver them from many superstitions and absurd prejudices. The study of the ancient classics and the department of learned research in the domain of national histories and literatures had an eminent representative in Gregorio Mayáns y Siscar (1699–1781), who worthily carried on the great traditions of the Renaissance; besides publishing good editions of old Spanish authors. Something of the old picaresque novel came to life again in the *Fray Gerundio* of the Jesuit Isla, a biographical romance which is also and above all a satire on the follies of the preachers of the day. One or two poets can be named. At the head of the new school is Meléndez Valdés, and with him are associated Diego González (1733–1794), José Iglesias de la Casa (1748–1791), known by his *letrillas*, Cienfuegos, and some others

Among the verse writers of the 18th century who produced odes and didactic poetry it is only necessary to mention Leandro Fernández de Moratín and Quintana. The poverty in lyric poetry is even exceeded by that of the stage. The only dramatist who was really successful in composing on the French pattern some pleasant comedies, is Leandro Fernández de Moratín There was one writer of talent, Ramón de la Cruz; nothing helps us better to an acquaintance with the curious Spanish society of the reign of Charles IV. than the interludes of this genial and light-hearted author.

19th Century Literature.—The struggle of the War of Independence (1808–14), exerted no immediate influence on the literature of Spain. One might have expected as a consequence of the rising of the whole nation against Napoleon that Spanish writers would no longer seek their inspiration from France, and would resume the national traditions which had been broken at the end of the 17th century. But nothing of the sort occurred. Not only the *afrancesados* (as those were called who had accepted the new régime), but also the most ardent partisans of the patriotic cause, continued in literature to be the submissive disciples of France It is true both of Quintana and of Martínez de la Rosa, who, though less impressive, had a greater independence of spirit and a more classical taste.

The first decidedly romantic poet of the generation which flourished about 1830 was the duke of Rivas whose drama of *Don Alvaro ó la fuerza del sino* inspired Verdi's opera *La Forza del Destino*. Espronceda is a cosmopolitan romantic of the school of Byron. An exclusively lyric poet, he did not live long, but what he has left is often exquisite. Zorrilla has a more unequal talent; nevertheless, among hasty performances, his *Don Juan Tenorio*, a fantastic version of the legend treated by Tirso de Molina, Calderón, Molière, Zamora, Shadwell and Byron, is a curious specimen of Spanish romanticism The play by García Gutiérrez, entitled *El Trovador*, inspired Verdi's well-known opera.

Bretón de los Herreros is the last of the dramatists who preserved the feeling of the ancient *comedia*. Mariano José de Larra, a prose writer of the highest talent, must be placed beside Espronceda, with whom he has several features in common Caustic in temper, he was specially successful in the political pamphlet, the *article d'actualité*, in which he ridicules the oddities of his contemporaries. Also, we have Mesonero Romanos, whose *Escenas matritenses* (1842), give pleasure by the curious details they furnish with regard to the contemporary society of Madrid. Estébanez Calderón in his *Escenas andaluzas* (1847) sought to revive the manner of the picaresque writers. Agustín Durán published highly esteemed collections of old Castilian literature.

Drama.—Foreign influence is most clearly marked in the work of Ventura de la Vega (1807–1865), whose relationship to the younger Moratín, and therefore to Molière, is unmistakable in *El Hombre de mundo* (1845), a piece written after a long apprenticeship spent in translating French plays. A fusion of early and later methods is discernible in the plays of Tamayo y Baus. Campoamor wrote dramas which, though curious as expressions of a subtle intelligence cast in the form of dialogue, do not lend themselves to presentation, and were probably not intended for the stage. The successor of Tamayo y Baus in popular esteem was José Echegaray, whose earlier plays—such as *La Esposa del vengador* and *En el puño de la espada*—are in the romantic style; in his later works he attempts the solution of social problems or the symbolic drama. Such pieces as *El Gran Galeoto, El Hijo de Don Juan* and *El Loco dios* indicate a careful study of the younger Dumas and Ibsen. José Felíu y Codina (1843–1897), a Catalan wrote two vigorous plays entitled *La Dolores* and *María del Carmen;* Joaquín Dicenta (b. 1860), showed daring talent in *Juan José*, while Jacinto Benavente (b. 1866), is a dramatist whose mordant vigour and knowledge of stage-effect was first manifested in *La Comida de las fieras* and *Rosas de otoño*

Poetry.—Rivas, Espronceda and Zorrilla owed more to foreign models than either Campoamor or Núñez de Arce. Campoamor has been described as a disciple of Heine, but he in fact continued in his own semi-philosophic fashion a national tradition of immemorial antiquity—the tradition of expressing lyrical emotion in four or eight lines which finds its most homely manifestation in the five volumes of *Cantos populares españoles* edited by Francisco Rodríguez Marín No less national a poet was Núñez de Arce, whose best performance is *Gritos del combate* (1875). Absorbed by commerce, Vicente Wenceslao Querol (d. 1889) is represented by a single volume of poems as remarkable for their self-restraint as for a deep tenderness which finds expression in the *Cartas á María* A more powerful and interesting personality was Joaquín María Bartrina (1850–1880), who endeavoured to transplant the pessimistic spirit of Leconte de Lisle to Spanish soil. Salvador Rueda (b 1857), in his *Aires españoles*, represents the vivid colouring and resonant emphasis of Andalucía; Vicente Medina (b 1866) in *Aires murcianos* and *La Canción de la huerta* reproduces with vivid intensity the atmosphere of the Murcian orchard-country. José María Gabriel y Galán (d. 1905), was extremely unequal, and his range of subjects was limited, but in *El Ama* he produced a poem which is unsurpassed in the Spanish poetry of its time But more truly a poet than any of these was Rosalía de Castro, whose one volume of poems not in the Galician dialect, *En las orillas del Sar*, was published in 1884

Fiction.—Since 1850 there has been a notable renaissance of the Spanish novel Fernán Caballero is entitled to an honourable place in literary history as perhaps the first to revive the native realism which was temporarily checked by the romantic movement. In all that concerns truth and art she is superior to the once popular Manuel Fernández y González (d 1888), of whom it has been said that Spain should erect a statue to him and should burn his novels at the foot of it Antonio de Trueba followed Fernán Caballero in observing local customs. He had no gift of delineating character, and his plots are feeble; but he was not wanting in literary charm, and went his road of incorrigible optimism amid the applause of the crowd. His contemporary, Pedro Antonio de Alarcón, is remembered chiefly as the author of *El Sombrero de tres picos* (the Three-Cornered Hat), a delightful and peculiarly Spanish tale of picaresque malice, more than once translated into English. José María de Pereda is the founder of the modern school of realistic fiction in Spain, and the boldness of his experiment startled a generation of readers accustomed to Fernán Caballero's feminine reticence and Trueba's deliberate conventionality.

His rival, Juan Valera, is not, in the restricted sense of the word, realistic, but he is no less real in his own wider province; he has neither Pereda's energy nor austerity of purpose, but has a more infallible tact, a larger experience of men and women, and his sceptical raillery is as effective a moral commentary as Pereda's Christian pessimism. In Valera's *Pepita Jiménez* and *Doña Luz*, and in Pereda's *Sotileza*, we have a trio of Spanish heroines who deserve their fame. Benito Pérez Galdós gave a new life to the historical novel in his huge series entitled *Episodios nacionales*. The colouring is so brilliant, the incident is so varied and so full of interest, the spirit so stirring and patriotic, that the born Spaniard easily forgives their frequent prolixity. Their appeal is irresistible; there is also a considerable public for the politico-religious novels such as *Doña Perfecta, Gloria* and *León Roch*, which have been published in English versions. The quick response of Pérez Galdós to any external stimulus, his sensitiveness to every change in the literary atmosphere, made it inevitable that he should come under the influence of French naturalism as he does in *Lo Prohibido* and in *Realidad;* but his conversion was

temporary, and two profound novels dealing with contemporary life—*Fortunata y Jacinta* and *Angel Guerra*—mark the third and culminating stage in the development of one of the greatest of Spanish novelists. The talent of Armando Palacio Valdés was first displayed in *El Señorito Octavio*. Two subsequent works—*Marta y María* and the delightful *La Hermana San Sulpicio*—raised hopes that Spain had, in Palacio Valdés, a novelist of the first order to succeed Valera; but in *La Espuma* and *La Fe*, two social studies which contained caricatures of well-known personages, the author ceased to be national and did not become cosmopolitan.

Another novelist who for a time divided honours with Palacio Valdés was Emilia Pardo Bazán. The powerful, repellent pictures of peasant life and the ethical daring of *Los Pazos de Ulloa* and *La Madre Naturaleza* are set off by graphic passages of description; and the local patriotism which inspires *Insolación* and *De mi tierra* is expressed in a style which secures Emilia Pardo Bazán a high place among her contemporaries. Leopoldo Alas (1851–1901), who used the pseudonym of "Clarín," was better known as a ruthless critic than as a novelist; the interest of his shorter stories has evaporated, but his ambitious novel, *La Regenta*, lives as an original study of the relation between mysticism and passion. Jacinto Octavio Picón (b. 1852), who deserted novel writing for criticism, displayed much insight in Lázaro, the story of a priest who finds himself forced to lay down his orders; this work was naturally denounced by the clerical party, and orthodoxy declared equally against *El Enemigo* and *Dulce y sabrosa;* more impartial critics agree in admiring Picón's power of awakening sympathy and interest, his gift of minute psychological analysis and his exquisite diction. Angel Ganivet (d. 1898) produced in *Los Trabajos del infatigable creador Pio Cid* a singular philosophical romance, rich in ideas and felicitous in expression, though lacking in narrative interest. Ramón del Valle Inclán (b. 1869) tends to preciosity in *Corte de Amor* and *Flor de Santidad;* but in his four *Sonatas, Primavera, Estío, Otoño* and *Invierno* (which have been translated into English), he has produced a masterpiece, and in the protagonist, the Marqués de Bradomín, a great character. (J. F.-K.; J. B. T.)

CONTEMPORARY LITERATURE (1910–1928)

The dominant feature of contemporary Spanish literature may be found in a more conscious realization of the creative element of the race by its critical element and in a tendency towards the fusion of both these elements into a complete whole. With the death of Galdós, the sceptre of Spanish literature passes to Miguel de Unamuno, who represents the modern version of the Spanish mystic writer. His main concern is the relation of man to creation. It is the subject of his masterpiece *Del Sentimiento Trágico de la Vida* (1913), a book of passionate meditation (of which an excellent translation exists in English, *The Tragic Sense of Life*, 1921), and as an attitude of mind it dominates his criticism: *En torno al Casticismo* (1902), *Ensayos* (1916), *La Agonía del Cristianismo* (1926); his novels: *Niebla* (1914), *Abel Sánchez* (1917), *Tres Novelas Ejemplares y un Prólogo* (1920) and his play: *Fedra*. In these works Unamuno appears as the apostle of an ideal of life more closely connected with spiritual Easternism than with the intellectual and social tenets of the West. He thus fulfils in Spain much the same function as Dostoievsky did in Russia, for Spain like Russia is a transition between East and West. He aims at intensity rather than extension. His style is not unlike the style of Carlyle in that it is written with the whole being of the man, body and soul.

If, in order to complete the parallel with Russia, a Spanish western type of mind had to be opposed to Unamuno, as Turgenev could be opposed to Dostoievsky, a younger man, José Ortega y Gasset, might be selected for this purpose. Ortega y Gasset is a refined humanist, strongly influenced by German contemporary Neo-Kantian schools of thought. His main work is in the field of criticism and psychology—*Meditaciones del Quijote* (1911), *El Espectador* (1917). In more recent books he has endeavoured to draw philosophical and psychological conclusions from current events; for instance, in the field of politics with his *España invertebrada* (1922) and in that of philosophy and science with *El tema de nuestro tiempo* (1923), a masterly commentary on the new vistas opened out to thought by the discoveries of Einstein. In this same school may be included José Martínez Ruiz (b. 1876), better known under his literary name of "Azorín," whose art has all the finish and exquisiteness, and all the smallness as well, of miniature painting. He has the rarer merit of applying these gifts to the interpretation of national scenes and places, as in his *Castilla* (1920); *Los Pueblos* (1905); *La Ruta de Don Quijote* (1905), and has thus contributed in no small measure to the movement for national self-knowledge which is noticeable in contemporary Spain.

Fiction.—In fiction, though belonging to an older generation, Vicente Blasco Ibáñez must be mentioned. His war novel *Los*

Cuatro Jinetes del Apocalipsis (1916, Eng. trans. 1918) made him famous with the English-speaking public. Older novels (and better ones) have been translated, such as *La Barraca* (1899), *Sangre y Arena* (1908), *The Matador* (1918) and *The Cabin* (1919). Blasco Ibáñez represented an art which is Spanish only in its subject but not in its spirit, manner or style.

Of a younger generation, Pío Baroja (b. 1872) is perhaps the most widely read. A Basque, with all the acuteness of mind of his race and not a little of its rustic independence and antagonism to civilization, Baroja writes abundantly and carelessly with more spirit than art. His best work is perhaps *Idilios Vascos*, in which he has rendered the quaint charm of his own country. Many of his works have been published in English by American publishers. To this generation belongs also Ricardo León, who writes in a more consciously traditional vein and pays considerable attention to matters of style. His main work is *Casta de Hidalgos* (1908). Concha Espina, a brilliant woman novelist, has distinguished herself by novels of psychological insight and easy style, such as *El Metal de los Muertos* (1920).

Ramón Pérez de Ayala (b. 1881) is perhaps the best novelist of the younger generation. A critic of great talent and a poet, he has written several novels, the best of which are *Novelas Poemáticas de la Vida Española* (1916, translated into English under the title of *Prometheus*) and *Belarmino y Apolonio* (1921) He is a typical exponent of the fusion of the traditional Spanish spirit with the conscious knowledge of its resources referred to above, as characteristic of contemporary literature in Spain. The same may be said of Gabriel Miró, whose delicate sensibility and deep knowledge of the language make him one of the most richly endowed authors of contemporary Spain. Among his works are *El Humo Dormido* (1920); *El Libro de Sigüenza* (1921); *Figuras de la Pasión del Señor* (1916, this last translated into English 1924) Of recent years several authors have cultivated the utopian and satirical variety of novel-writing. To this kind belong *El Archipiélago Maravilloso* (1923) by Luis Araquistain, and *La Girafa Sagrada* by S. de Madariaga (originally written in English and published 1925) Among newcomers in novel-writing Claudio de la Torre and Felix Urabayen, *El Barrio Maldito* (1925) must be singled out.

Drama.—Jacinto Benavente still dominated the Spanish theatre during this period. His most famous play, *Los Intereses Creados* (1907), is not representative, for it illustrates but one phase of the talent of this many-sided author. A more powerful tragedy, *La Noche del Sábado* (1903), is of the same period. In more recent times he has given an intense drama of life in *La Malquerida* (1913). There is, however, a type of play in which Benavente must yield the prize to the brothers Álvarez Quintero (Serafín, b. 1871; Joaquín, b. 1873). As authors of Comedias de Costumbres these two writers, who always work together, are unsurpassed. The list of their comedies is long, and includes *Las de Caín* and *Puebla de las Mujeres* (1912). Other playwrights of note are Linares Rivas (b. 1866), remarkable for his skill in the handling of dialogue; Martínez Sierra, a name which stands for the collaboration of Don Gregorio Martínez Sierra (b. 1881) and his wife, resulting in a happy blend of dramatic skill and delicate psychology; and Pinillos (Parmeno) (1875–1923), a vigorous painter of social conflicts. The poetical theatre still lives in Spain, maintained by Valle-Inclán (b. 1870), Marquina, Cata and Ardavín. In recent years a writer of unusual power, Jacinto Grau, has conquered the foreign stage, particularly with his *El Conde Alarcos* (1917), *El Hijo Pródigo* (1918). But drama and comedy are only one, and that not the most important, aspect of the Spanish theatre. Still more typical of the nation is what is modestly known in Spain as *Género chico* (small genre), a type of theatrical production consisting of plays generally short and accompanied by music and ranging from variety pieces akin to operettas to little masterpieces of musical drama. Its best-known exponents are the brothers Quintero and Carlos Arniches (b. Alicante, 1866).

Poetry.—The two main influences acting on Spanish poetry towards the close of the 19th century, *i.e.*, national tradition and the example of foreign poetry, particularly that of the symbolist school of France, which reaches Spain through South-American poets, such as Rubén Darío, are still at work. Though the first is the more vigorous and conscious, the second widens so as to include all influences: D'Annunzio, Maeterlinck, Tagore. More typically national are Unamuno, *Rosario de Sonetos Líricos* (1911), *El Cristo de Velázquez* (1920); Antonio Machado (b. 1875), whose pessimistic serenity is in keeping with the landscape of central Spain (*Soledades*, *Campos de Castilla*) and Salvador de Madariaga (b. 1886), whose *Romances de Ciego* (1922) re-state in a new form the old Spanish theme of Jorge Manrique Other poets produce under more complex influences Thus Manuel Machado (b. 1874), whose main inspiration is popular and southern has, nevertheless, written excellent verse in which the influence of French elegant sensibility is discernible; Juan Ramón Jiménez (b. 1881), remarkable rather for exquisite sensitiveness than for power is led by his melancholy moods towards fluid rhythms which, though more settled, are reminiscent of Maeterlinck and, through him, of Rossetti. Ramón del Valle-Inclán (1870), perhaps the most skilful musician among modern Spanish poets, has given in *La Marquesa Rosalinda* (1913) an admirable example of the adaptability of the Spanish language to the most exquisite and complicated rhythms. Ramón Pérez de Ayala in his three volumes, *La Paz del Sendero* (1916); *El Sendero Innumerable* (1916); and *El Sendero Andante* (1921), effects a happy union of thought with harmonious poetry in a work not wholly uninfluenced by Francis Jammes, D'Annunzio and Walt Whitman. Among the rising generation may be mentioned Pedro Salinas, Jorge Guillén, García Lorca and Rafael Alberti

Miscellaneous—In the field of erudition and literary history the task of Menéndez y Pelayo is continued by Don Ramón Menéndez Pidal, whose works on the "Cantar de Mio Cid" (1911, 1913, etc.) and on the Spanish Chronicles have thrown much light on the origin of Spanish epic poetry. Francisco Rodríguez Marín (b. 1855), editor of *Don Quijote*, a specialist of Spanish folk lore, has succeeded the Master as head of the National Library. Father Asín has won world-wide fame by his illuminating work on the Arabic origins of Dante. Of the younger generation Federico de Onís (b. 1885) has edited *Fray Luis de León* (1914) and Américo Castro (b 1885) has worked on *Lope de Vega* (1919).

CATALAN LITERATURE

Poetry in the Middle Ages.—Although the Catalan language is a branch of the southern Gallo-Roman, the literature, in its origin might be considered as supplementary to that of Provence. Until about the second half of the 13th century the poets of north-eastern Spain used no other language than that of the troubadours. Guillem de Bergadan, Uc de Mataplana, Ramón Vidal de Besalú, Guillem de Cervera, Serveri de Gerona, were all genuine Provençal poets, in the same sense as are those of Limousin, Quercy or Auvergne, since they wrote in the *langue d'oc* and made use of all the forms of poetry cultivated by the troubadours north of the Pyrenees. Ramón Vidal (end of the 12th century and beginning of 13th) was a grammarian as well as a poet; his *Dreita manera de trobar* became the code for the Catalan poetry written in Provençal, which he called *Lemosi*. From the combination of spoken Catalan with the literary language of the troubadours there arose a composite idiom. Among the oldest examples of this Provençalized Catalan verse are the poetical works of Raymond Lully or Ramón Lull (1235–1315), and one has only to read the fine piece entitled *Lo Desconort* ("Despair"), on some of his stanzas on religious subjects, to apprehend at once the eminently composite nature of that language. Muntaner (1265–1336), whose prose is exactly that spoken by his contemporaries, becomes a troubadour when he writes in verse; his *Sermó* on the conquest of Sardinia and Corsica (1323), introduced into his *Chronicle* of the kings of Aragon, exhibits linguistically the same

mixed character as is found in Lully. Catalan verse writers of the 14th century are not very numerous, nor are their works of any great merit. The majority of their compositions consist of what were called *noves rimades,* that is, stories in octosyllabic verse in rhymed couplets. There exist poems of this class by Pere March, by Torrella, by Bernat Metge (an author more celebrated for his prose), and by others whose names we do not know; among the works belonging to this last category special mention ought to be made of a version of the romance of the *Seven Sages,* a translation of a book on good breeding entitled *Facetus,* and certain tales where, by the choice of subjects, by various borrowings, and even occasionally by the wholesale introduction of pieces of French poetry, it is clearly evident that the writers of Catalonia understood and read the *langue d'oui.* Closely allied to the *noves rimades* is another analogous form of versification—that of the *codolada,* consisting of a series of verses of eight and four syllables, rhyming in pairs, still made use of in one portion of the Catalan domain (Majorca).

15th Century.—The 15th century is the golden age of Catalan poetry. At the instigation and under the auspices of John I. (1387–1395), Martin I. (1395–1410), and Ferdinand I. (1410–1416), kings of Aragon, there was founded at Barcelona a consistory of the "Gay Saber," on the model of that of Toulouse, and this official protection accorded to poetry was the beginning of a new style much more emancipated from Provençal influence.

The language begins to rid itself more and more of Provençalisms, and tends to become the same as that of prose and of ordinary conversation. With Pere and Jaume March, Jordi de Sant Jordi, Johan de Masdovelles, Francesch Ferrer, Pere Torrella, Pau de Bellviure, Antoni Vallmanya, and, above all, the Valencian Auzías March, there developed a new school, which flourished till the end of the 15th century, and which, as regards the form of its versification, is distinguished by its almost exclusive employment of eight-verse *cobles* of ten syllables, each with "crossed" or "chained" rhymes ending with a *tornada* of four verses. Auzías March (1379–1459), the most inspired, the most profound, but also the most obscure of the whole group, was printed in the 16th century; his *Cants d'amor and Cants de mort* contain the finest verses ever written in Catalan. He was admired by Santillane and translated into Castilian by Montemayor (1560). Of a wholly different class, and in quite another spirit, is the *Spill des dones* of Jaume Roig (d. 1478), a Valencian also, like March; this long poem is in quadrisyllabic instead of octosyllabic verse. A bitter and caustic satire upon women, it purports to be a true history—the history of the poet himself and of his three unhappy marriages in particular. Notwithstanding its author's allegations, however, the *Spill des dones* is mostly fiction; but it derives a very piquant interest from its really authentic element, its vivid picture of the Valencia of the 15th century and the details of contemporary manners. Amongst other poets, Joan Roiç de Corella (1430–1500), was the author of the *Tragedia de Caldesa* and an *Oració* to the Virgin Mary. After this bright period of efflorescence, Catalan poetry rapidly faded, a decline due more to the force of circumstances than to any fault of the poets. The union of Aragon with Castile, and the resulting predominance of Castilian throughout Spain, inflicted a death-blow on Catalan literature, especially on its poetry. The fact that a Catalan, Juan Boscan, inaugurated in the Castilian language a new kind of poetry, and that the Castilians themselves regard him as the head of a school, is important and characteristic; the date of the publication of the works of Boscan (1543) marks the end of mediaeval Catalan poetry.

Prose of 13th–15th Centuries.—The earliest prose works in Catalan are later than the poems of the oldest Catalan troubadours of the Provençal school. Though the oldest Catalan document dates from between 1095 and 1110 (the text of an oath imposed on certain barons by a bishop of Urgell), and the *Homilies d'Organyá* are believed to date from the 11th century, literary prose dates no further back than the close of the 13th century. It has the advantage of being entirely original. The language is the very language of the soil which we see appearing in charters from about the time of the accession of James I. (1213). Its chronicles are the best ornament of mediaeval Catalan prose. Two of them—that of James I., apparently reduced to writing a little after his death (1276) with the help of memoirs dictated by himself during his lifetime; and that of Ramon Muntaner (1265–1336), relating at length the expedition of the Catalan company to the Morea and the conquest of Sardinia by James II., are distinguished alike by the artistic skill of their narration and by the quality of their language; it would not be too much to liken these Catalan chroniclers, and Muntaner especially, to. Villehardouin, Joinville and Froissart. The Doctor Illuminatus, Raymond Lully, who, though he knew Arabic, had a poor acquaintance with Latin—his philosophical works were done into that language by his disciples—wrote in a somewhat Provençalized Catalan various moral and propagandist works—the romance *Blanquerna,* the *Libre de les maravelles,* into which is introduced a "bestiary" taken by the author from *Kalilah and Dimnah,* and the *Libre del orde de cavalleria,* a manual of the perfect knight, besides a variety of other treatises and opuscula of minor importance. The majority of the writings of Lully exist in two versions—one in the vernacular, which is his own, the other in Latin, originating with his disciples, who desired to give currency throughout Christendom to their master's teachings. Recent research has proved that Lully's peculiar method of exposition and many of his ideas were taken from Muslim Spanish mystics and *sūfis.* Lully—who was very popular in the lay world, although the clergy had á low opinion of him, and in the 15th century even set themselves to obtain a condemnation of his works by the Inquisition—had a rival in the person of Francesch Eximeniç (1340–1409). His *Crestia* (printed in 1483) is a vast encyclopaedia of theology, morals and politics for the use of the laity. The *Libre de les dones,* which is at once a book of devotion and a manual of domestic economy, contains a number of curious details as to a Catalan woman's manner of life and the luxury of the period.

In the 15th century, Bernat Metge, himself well versed in Italian literature, presents some of its great masters to his countrymen by translating Boccaccio's story of Griselde from the Latin version made by Petrarch, and also by composing *Lo Sompni* (*"The Dream"*), in which the influence of the Italy of the 13th and 14th centuries is very perceptible. The chivalrous romance, *Tirant lo blanch* (finished in 1460 and printed in 1490), one of the few books saved from the library of Don Quixote, was mainly the work of Johanot Martorell of Valencia. *Curial y Guelfa* is an anonymous romance of the end of the 15th or beginning of the 16th century. The beginnings of the drama in Catalan are represented by *The Mystery of Elche,* a 15th century Assumption play based on an earlier *Representacio.* It is still performed every year at Elche, on Aug. 14 and 15, and is sung throughout to traditional music.

16th–18th Centuries.—With the loss of political was bound to coincide that of literary independence in the Catalonian countries. Catalan fell to the rank of a patois. The 16th century, in fact, furnishes literary history with hardly more than a single poet at all worthy of the name—Pere Serafi, some of whose pieces, in the style of Auzías March, but less obscure, are graceful enough and deserve to live; his poems were printed at Barcelona in 1565. Prose is somewhat better represented, but scholars alone persisted in writing in Catalan—antiquaries and historians like Miquel Carbonell (d. 1517), compiler of the *Chroniques de Espanya* (printed in 1547), Francesch Tarafa, author of the *Cronica de cavallers catalans,* Anton Beuter and some others not so well known. In the 17th and 18th centuries the decadence became still more marked. Catalan had become the medium of familiar conversation, the language of folk-songs and ballads, printed in the *Romancerillo catalán* of Milá y Fontanals; but in these it lived on until the re-awakening at the beginning of the 19th century.

Revival of Catalan Language and Literature.—In 1814 appeared the *Gramática y apologia de la llengua cathalana* of Joseph Pau Ballot y Torres. The pioneers of reform, however, soon realized that ancient Catalan had fallen out of touch with their spiritual needs. They were living in an atmosphere of romantic mediaevalism, yet they found that a mediaeval literary

language was inadequate for their purpose. Again, the popularity of the satirical poems and farces of José Robreño (1780–1838) was a serious obstacle, owing to the corruption of the language in which they were written, while Federico Soler (1839–95) openly advocated *Catalá qu'ara es parla* ("Catalan as she is spoke") in opposition to the literary language. The development of modern Catalan, however, has been steadily in the direction of a refined means of expression for contemporary thought. Aribau's patriotic *Ode* (1833), the poems of Victor Balaguer (1823–1901) led to the imagination and mysticism of Jacinte Verdaguer (1845–1902), whose epic woven round the figure of Columbus (*L'Atlántida*) is a noble conception and a great poem. The Majorcan poems of Tomá Aguiló, with their vague, fantastic charm, were followed by those of Miguel Costai Llabera; while a strong formal sençe was brought in by Juan Alcover (d. 1926) and Gabriel Alomar. Catalonia found its first modern poet of real greatness in Joan Maragall (1860–1911). Contemporary poets have still further refined the language, so that it has become an exquisite instrument for the expression of poetry The chief names are Josep Carner (b. 1884), J. M. López-Picò (b. 1886), and J. M. de Sagarra.

The foundations of modern Catalan prose were laid by Joaquín Rubio y Ors (1818–99), by José Torres i Bagés, archbishop of Vich and author of *La tradició catalana* (1892). Francisco Pi i Margall, president of the Spanish republic of 1873, showed complete mastery over both Catalan and Castilian Fiction was inaugurated by Narciso Oller with *Papallona* (1880). One of the best prose-writers of the Catalan movement was Eugeni d'Ors ("Xenius"), part of whose *Glosári* (1906–17), was translated into Castilian before the author abandoned Barcelona for Madrid and began himself to write in Castilian His exquisite philosophical tale, *La Ben Plantada*, is one of the most notable achievements of the Catalan mind and the Catalan language

In the theatre, too, Catalan dramatists have produced work of considerable originality. Angel Guimerá achieved European reputation with *Terra baixa* (1896), which was made into the opera *Tiefland* by Eugen d'Albert and has been translated into English as *Martha of the Lowlands*. Beginning with historical tragedy (*Gala Placidia*, 1879; *Judith de Welp*, 1883), he turned to rural drama in *La Boja* (1890), comedy in *La Baldirona* and *La Sala d'espera*, and modern tragedy in *Martha Rosa* (1894), and *La festa del blat* (1896). His last work, *Jesus que torna*, was brought out during the World War of 1914–18. Interesting dramatic work was also produced by Ignacio Iglesias (d. 1928), whose long series of social dramas—inspired originally by the early works of Gerhardt Hauptmann—produced something of a masterpiece in *Els Vells*. For a time he fell under the influence of Maeterlinck (e g, *Focfollet, Cendres d'amor*) and eventually turned to pure comedy, in *Girassol*. Adrián Gual is the author of several works of fancy and originality, but his best work has been done as director of *Teatre Intim*, an "art-theatre" in Barcelona, founded in 1898, which produced works of pioneer tendencies Santiago Rusiñol, a distinguished painter, achieved an unqualified success in a play with incidental music by Enric Morera, *L'Alegría que passa*, since when he has written a number of plays, including *L'Heróe, El Mistic, El Indiano*, etc.

The Catalan language is now used for valuable works in all branches of science and art, history and music. Linguistic studies have received invaluable support from the *Institut d'Estudis Catalans*, with its fine library and numerous publications.

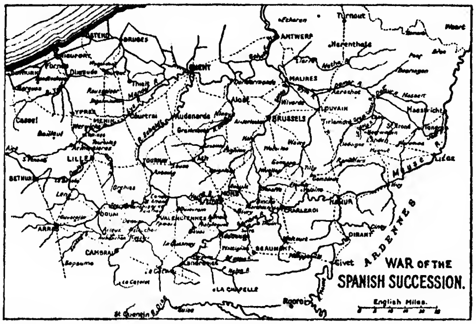
SPANISH MOSS (*Tillandsia usneoides*), the name given to a plant of the family Bromeliaceae which hangs in long festoons from the branches of trees in tropical and sub-tropical American forests, being especially conspicuous on the live oak in the southern United States. The whole plant is covered with scaly hairs for the absorption of water, giving it a grey colour It is used like horse-hair From its appearance, which resembles a lichen, it is sometimes called old man's beard.

SPANISH SUCCESSION, WAR OF THE, the name given to the general European war which began in 1701 and ended with the Treaties of Utrecht and Rastatt in 1713–14. Its monotonous round of marches and sieges is often quickened by the genius of three great soldiers, Marlborough, Eugene and Villars, while Peterborough and Galway, Catinat and Vendôme, though less highly gifted, were men of unusual and conspicuous ability. As usual in these wars, manoeuvres, threats and feints played the principal part in field warfare The tangible assets, at the conclusion of peace, the effective seizure of fortresses and provinces was in most cases the principal object with which kings and princes made war. Nevertheless, the object of this war, at least in the case of England and Holland, was less to add a few cities and districts to their own domains than to cripple the power of Louis XIV. The ambition of the *Grand Monarque* by placing on the throne of Spain his grandson Philip, had brought into politics the fear not merely of a disturbance but of an entire overthrow of the "Balance of Power." Thus the instrument of his ambition, his magnificent army, was (above all for England) an object in itself and not merely an obstacle to the attainment of other objects. Many of the allies, however, had good reason to fear for their own possessions, and others entered the alliance with at least the hope of acquiring a few material gains at small expense On the side of the allies therefore, throughout the war, there was a perpetual struggle between offensive activity and defensive passivity

The action of Louis XIV in the matter of the Spanish succession had been foreseen, and William III of England devoted his last years to providing against the emergency by the formation of a coalition to deal with it, and the production of a claimant for the Spanish throne, the archduke Charles The coalition naturally grew out of the Grand Alliance (*see* GRAND ALLIANCE, WAR OF THE), and consisted of Austria, some of the German states, Great Britain, Holland, Denmark and Portugal On the other side Louis XIV was supported by Spain—where Philip, recognized as heir by the dying Charles II, had been promptly installed—Bavaria and Cologne A doubtful ally was the duke of Savoy, whose policy was to secure and aggrandise himself by adhering at each moment to the stronger party.

Italy Chiari 1701.—The war began, to all intents and purposes, with the handing over of the fortresses in the Spanish Netherlands to the French in March 1701. England and Holland at once began their preparations, but neither state was able to put an army in the field in the year—England because her peace-time army was absolutely insignificant, and Holland because she dared not act alone. In Italy, however, the emperor took the initiative, and an Austrian army under Prince Eugene, intended to overrun the Spanish possessions in the Peninsula, assembled in Tirol in

the early summer. The French army under Catinat blocked the defile of Rivoli, but secretly reconnoitred passages over the mountains between Roveredo and the Vicenza district in neutral Venetian territory. On May 27, taking infinite precautions as to secrecy, and requesting the Venetian authorities to offer no opposition so long as his troops behaved well, Eugene began his march by paths that no army had used since Charles V.'s time, and on the



DRAWN BY BARTHOLOMEW & SONS, LTD., EDINBURGH

28th his army was on the plains. Catinat was surprised, for he had counted upon Venetian neutrality, and when, in the search for a passage over the lower Adige, Eugene's army spread to Legnago and beyond, he made the mistake of supposing that the Austrians intended to invade the Spanish possessions south of the Po. He thinned out his line to cover all the front as far as that river. But Eugene found an unguarded spot. With the usual precautions of secrecy (deceiving even his own army), he crossed the lower Adige in the night of July 8–9. Catinat at once concentrated his scattered army backwards on the Mincio, while Eugene turned northward and regained touch with his old line of supply, Roveredo-Rivoli. For some time Eugene was in great difficulties for supplies, as the Venetians would not allow his barges to descend the Adige. At last, however, he made his preparations to cross the Mincio close to Peschiera and well beyond Catinat's left. This was executed on July 28. It seems that the marshal was well content to find that his opponent had no intention of attacking the Spanish possessions in the Peninsula, at any rate he fell back quietly to the Oglio. But his army resented his retreat before the much smaller force of the Austrians and, early in August, his rival Tessé reported this to Paris, whereupon Marshal Villeroy, a favourite of Louis, was sent to take command. The new commander was the least competent of all the French senior officers. Ere long he attacked Eugene in a well entrenched position at Chiari (Sept. 1), and was thoroughly defeated, with a loss, it is said, of 3,000 to the Austrians' 150.

As yet there was no declaration of war by either party. Preparations were made by both sides during the year, most vigorously of all by Louis, who set on foot no less than 450,000 regulars and embodied militia, and had always prided himself on being first in the field. But the début was disheartening, and in the winter a fresh mishap befell the French. Eugene surprised Cremona on the night of Feb. 1, 1702, and, after a confused fight, drew off, taking with him Villeroy as a prisoner. The rest of the French army thereupon retreated, while Eugene quietly resumed his winter quarters and his blockade of Mantua.

Marlborough's First Campaign.—With the year 1702 the real struggle began. Villars and one or two others of Louis's counsellors urged the king to concentrate his attention on the Rhine and the Danube, where, they pointed out, was the centre of gravity of the coalition. This advice was disregarded, and with political aims, the largest French army was employed on the side of the Meuse, while the Rhine front was entrusted to smaller forces acting on the defensive. In Italy the balance of power remained unchanged, except that one of Louis's best generals, Vendôme, was sent to replace the captured Villeroy. In the Low Countries, Ginckell, earl of Athlone, the interim commander of the allies (English, Dutch and minor German states), was at the outset outmanoeuvred by the French (Boufflers), and the momentary threat of a French invasion had a lasting effect on the Dutch authorities, whose timidity thereafter repeatedly ruined the best-laid schemes of Marlborough, who was obliged to submit to their obstruction and their veto. This handicap, moreover, was not the only one under which Marlborough suffered. Unless it is realized and borne in mind that the great captain was struggling against factiousness and intrigue in England and against jealousies, faint-heartedness and disagreements amongst the states who lent their contingents to his miscellaneous army, the measure of his achievements in ten years seems small. But in fact it was marvellous. Under 18th-century conditions of warfare, and with an army so composed that probably no other man in Europe could have held it together at all, obstructed and thwarted at every turn, he yet brought Louis XIV. and France to the very edge of ruin.

In this theatre of war the French, in concert with the garrisons of the Spanish Netherlands, had fortified a line of defence more than 70 m. long from Antwerp to Huy, as well as another line, longer but of only potential importance, from Antwerp along the Scheldt-Lys to Aire in France. Besides the "lines of Brabant" Boufflers held all the Meuse fortresses below Huy except Maestricht. Marlborough concentrated 60,000 men (of whom 12,000 only were British) about Nijmwegen in June, and early in July, having made his preparations, he advanced directly by Hamont on Diest. Boufflers hastily fell back, in order to regain the Brabant lines. Marlborough, with the positive object of bringing his opponent to battle at a disadvantage, won the race and awaited the arrival of Boufflers' tired army to strike it a paralysing blow. But at the critical moment the Dutch deputies forbade the battle, content to see the army that had threatened Holland with invasion driven off to a safe distance without bloodshed (July 22). After this experience Marlborough thought it prudent to pacify the Dutch by besieging the Meuse fortresses, several of which fell in rapid succession (September–October). Boufflers fell back within the defended area of the lines of Brabant, and the campaign closed with the capture of Liége by the allies (Oct. 12). Marlborough was created a duke on his return to England in November. He had checked the main enterprise of the French, and every man in the army knew that but for the Dutch deputies the enemy would have been destroyed.

Friedlingen.—On the Rhine the campaign was, except for two disconnected episodes, quite uneventful. The Imperialists under a methodical general, the margrave Louis of Baden, gathered in the Neckar country and crossed the Rhine above Spire. Catinat, now old and worn out, was sent to Strasbourg to oppose the threatened invasion of Alsace, and, like MacMahon in 1870, he dared not assemble his whole force either on the Lauter or on the Ill. The margrave invested Landau (July 29) and with a covering army occupied the lines of the Lauter about Weissenburg, which Catinat did not attack. Hence Landau, valiantly defended by Melac, had to be surrendered on Sept. 12. But at the same time the elector of Bavaria took the side of France, surprised Ulm, and declared a local war on the house of Austria and the "circles" of Swabia and Franconia. The margrave then, in order to defend his own country, hurried to Kehl with the greater part of his army, leaving a garrison in Landau and a corps of observation on the Lauter. To co-operate with the elector, Catinat had made up a corps out of every available battalion and squadron and placed it under Lieut.-General Villars. This corps drew away into Upper Alsace and the margrave followed suit until the two armies faced one another on opposite sides of the Rhine near Huningen. Villars crossed the Rhine and won the first victory of his brilliant career at Friedlingen (opposite Huningen). Soon afterwards he placed his army in winter quarters in Alsace, and Louis of Baden disposed his troops in two entrenched camps opposite Breisach and Strasbourg respectively. In Italy Vendôme, superior in numbers but handicapped by instructions from Versailles and by the necessity of looking to the Italian interests of King Philip, gained a few minor successes over Eugene. A very hard-fought and indecisive battle took place at Luzzara on the Po on Aug. 15.

In the next two years Bavaria was the centre of gravity of the French operations, and only campaigns of the methodical and non-committal kind were planned for Italy and the Low Countries. In this year began the Camisard insurrection, in the Cevennes, which necessitated the detachment of a considerable body of troops from Vendôme's army in Italy.

In the Netherlands the French field army was behind the lines of Brabant, the Spanish troops in the lines of Flanders (Antwerp-Ghent-Aire) Together the two considerably outnumbered Marlborough (90,000 against 50,000), but the duke managed to be first in the field. After capturing Bonn in May, Marlborough's plan was to break the immensely long line of defence of the French and Spaniards by the capture of Antwerp. One Dutch corps under Coehoorn was to assemble in the Sluys-Hulst region, and another under Opdam at Bergen-op-Zoom while Marlborough, after manoeuvring Villeroy's field army out of the way, was to join them before the fortress. Marlborough executed his own share of the movement with his usual skill, but the Dutch generals enabled the French to emerge from the manoeuvre with a handsome victory Great projects were now entertained by the French, nothing less than the capture of Vienna by a Franco-Bavarian-Hungarian army being the intention The elector of Bavaria insisted that Villars should cross the Black Forest and join him, which Villars was unwilling to do thus early in the year, as two-thirds of his officers were as usual on leave or detached on recruiting duties. Courtier though he was, the marshal would not stir even in spite of the king's orders until he was ready. At the end of April, leaving Tallard alone to defend Alsace against the margrave of Baden, Villars plunged into the defiles of the Black Forest and on May 8 joined the elector at Ebingen All seemed favourable for the advance on Vienna, but at the last moment the elector half repented of his alliance with the enemies of Germany and proposed instead a junction with Vendôme in Italy by way of Tirol This proposal came to nothing, the Tirolese were soon roused to revolt by the misconduct of the ill-disciplined Bavarians, and Vendôme, who, like Luxembourg, was a giant in battle and a sluggard in camp, would not stir

Hochstett, 1703.—Villars had posted a protective force at Ulm to contain the Margrave's army should it turn back upon him, and this, after an engagement at Munderkingen (July 31) induced the cautious Louis to return to the Rhine. Five weeks later, however, the Margrave returned in full force, and moving by the right bank of the Danube reached Augsburg on Sept. 6. The elector, returning from his futile Tirol expedition, had already rejoined Villars at Dillingen, and the marshal persuaded him to attack the Austrian army that covered Vienna before the two imperial generals could join forces. The result was the battle of Hochstett (Sept. 20) in which the elector and Villars won a great victory, at a loss of only 1,000 men to the enemy's 11,000 Rarely indeed had an 18th-century general so great an opportunity of finishing a war at one blow. But even Villars saw no better use for the victory than the unimpeded junction of his own army and Tallard's and winter quarters in Wurttemberg. But Tallard remained on the Rhine, and Villars in disgust applied to be recalled. The Margrave, entrenched as usual, kept the field for another month and then retired to the Lake of Constance, where, in a still unexhausted district, he spent the winter. Tallard meanwhile invested Landau which surrendered on Nov. 12 Old Breisach, besieged by Vauban, capitulated on Sept. 6. Thus in Germany, though the grand advance on Vienna had come to nothing, the French had won important successes and established an army in Bavaria. In Italy, on the other hand, Vendôme, although no longer opposed by Eugene, achieved nothing.

Rhine and Danube Campaign, 1704.—The campaign of 1704, though in the Low Countries and in Italy practically nothing was done, is memorable for what was perhaps the greatest strategical operation in the 18th century, Marlborough's march to the Danube. At the outset the elector and Marsin (Villars' successor) were on the Iller, between Ulm and Memmingen, Tallard between Strasbourg and Landau, Villeroy as usual between the Brabant lines and the Meuse. On the other side the Margrave Louis was in the Stockach-Engen region. Responsible for guarding the whole of the Middle Rhine as well as for opposing the elector he was weak everywhere, and his defence of the Rhine was practically limited to holding the "lines of Stollhofen," a defensive position near Buhl in Baden. With Breisach and Kehl in their own hands, the French were more or less closely in touch with their comrades in Bavaria, and Tallard convoyed a large body of recruits for Marsin's army through the Black Forest defiles. But in doing so he lost most of them by desertion, the Margrave's army dogged his march, and in fact no regular line of communication was established Marlborough's purpose at any rate was quite definite—to transfer a large corps from the Low Countries to Bavaria and there in concert with the allies in that quarter to crush the elector decisively, but rather than be burdened with Dutch counsellors he chose to forgo the assistance of the Dutch troops. These were left under Overkirk to defend the Meuse, and English and English-paid troops alone took part in the venture.

Marlborough's March to the Danube.—Marlborough calculated that as he progressed up the Rhine the French would collect to prevent his crossing, instead of themselves passing over to join the elector and Marsin. Thus the expedition would reach the Neckar mouth, without its true purpose being suspected, and once there Marlborough would vanish from the ken of the defenders of the Rhine, to reappear on the Danube where he was least expected On May 12 the army crossed the Meuse at Ruremond, on the 23rd it reached Bonn, on the 29th Mainz. On June 1 the puzzled French noted preparations for bridging the Rhine at Philipsburg. But two days later the English had turned to their left into the valley of the Neckar. On June 10 Prince Eugene and on the 13th the Margrave appeared at the duke's headquarters to concert operations. It was arranged that the margrave was to join Marlborough and that Eugene should command the Stollhofen and other forces on the Rhine, for Tallard, it seemed, was about to be joined by Villeroy[1] and Marlborough knew that these marshals must be kept west of the Rhine for the six weeks he allowed himself for the Bavarian enterprise. The Margrave's army duly joined Marlborough's on June 22 at Ursprung, 12 m north of Ulm, where the elector and Marsin were encamped. The endurance of Marlborough's corps, as displayed in the long march from Ruremond, was not the least extraordinary feature of the operation For 18th-century troops such performances were generally provocative of desertion, and involved the ruin of the army that attempted it. But Prince Eugene, we are told, was astonished at the fine condition of the army On the French side meantime all was perplexity, and it was not until a week after the Margrave and Marlborough had joined, that Villeroy's main body from the Meuse started for Alsace to watch Eugene's corps, or rather the Stollhofen-Buhl position. This meant conceding both the initiative and the superiority in numbers to Marlborough.

Campaign on the Danube, 1704.—The duke had now manoeuvred himself with brilliant success from one theatre of war to another, and had secured every advantage to himself. From before Ulm he sidled gradually along the north side of the Danube in the hope of finding an unguarded passage. He and the Margrave exercised the general command on alternate days, and when on his own day he arrived opposite Donauworth, knowing Louis's caution, he thought that direct attack was better than another two days' extension to the east Moreover he needed a walled town to serve as a magazine. In the late afternoon of July 2 the army was flung, regardless of losses, against the entrenched hill of the Schellenberg at Donauworth, where the elector had posted a strong detachment. The attack cost 6,000 men, but it was successful, and of the 12,000 Bavarians on the hill only 3,000 returned to their main body, which had now moved from Ulm to Lauingen. Passing the river, the allies besieged and took the small fortress of Rain, and thence moved to the neighbourhood of Augsburg, thoroughly and deliberately devastating the country-side so as to force the elector to make terms. The best that can be said of this barbarous device, is that Louis XVI. had several times practised it. Its most effective condemnation is that military devastations, in these purely political contests, were entirely

[1]Even Villeroy it appears rose to the situation thus far, but the king only allowed him to send 25,000 men to Tallard.

unprofitable. Louis had already found them so, and had given up the practice. In the present case Marlborough's own supplies ran short, and his convoys were harassed. The movements of the two armies were but trifling. Marlborough, though superior, was not decisively superior, and his opponents, well entrenched near Augsburg, waited for Tallard and (in vain) for Villeroy. Marlborough marked time until Eugene should join him.

There were now five armies in the field, two allied and three French. The centre of gravity was therefore in Villeroy's camp. If that marshal followed Tallard, even Eugene's junction with Marlborough would not give the latter enough force. If Tallard alone joined the elector and Eugene Marlborough, the game was in the hands of the allies. But none of the possible combinations of two armies against one were attempted by either side. Eugene when informed that Tallard was on the move slipped away from Villeroy to join Marlborough. Tallard and the elector, aware of Eugene's march, were content to join forces peaceably at Augsburg. Villeroy, in whose hands was the key of the situation, hesitated and finally tried in vain to detain Eugene (who was already far away) in the Stollhofen lines. The last stage of the campaign was brief. Marlborough and Eugene had in mind a battle, Tallard and Marsin a war of manoeuvre to occupy the few weeks now to be spun out before winter quarters were due. The two allied armies met in the Danube valley on Aug. 6. If the enemy remained on the south side Eugene was to cross, if they recrossed to the north bank Marlborough was to follow suit. The margrave Louis of Baden had been sent off to besiege Ingolstadt as soon as Eugene had come within a safe distance. When therefore the French and Bavarians were reported opposite Eugene on the north side, Marlborough crossed at once, and without waiting for the margrave the two great soldiers went forward. On Aug. 2 (*see* BLENHEIM) they attacked and practically destroyed the armies of Tallard, Marsin and the elector.

Campaign of 1705.—The campaign of 1705 was uneventful and of little profit to either side. Marlborough's army had returned to the Low Countries. Villeroy had also returned to Brabant and retaken Huy. With him was the now exiled elector of Bavaria. On July 18, after a series of skilful manoeuvres, Marlborough forced the lines of Brabant at Elissem near Tirlemont, but not even the glory of Blenheim could induce the Dutch deputies to give him a free hand, or the Dutch generals to fall in with his schemes. King Louis was thus able to reinforce Villeroy betimes from Villars's Lorraine army, and the campaign closed with no better work than the razing of the captured French entrenchments. On the Rhine Villars, with a force reduced to impotence, carried on a spiritless campaign against the Margrave Louis. In Italy there was serious fighting. Here Vendôme's army engaged in the attempt to subdue Victor Amadeus of Savoy and was so far successful that the duke implored the emperor for aid. Eugene was sent with new reinforcements, opposed to which was a force under Vendôme's brother Philippe, called the Grand Prior. This man, a lazy dilettante, let himself be surprised by Eugene's fierce attack on the line of the Adda. The day was restored however, and the Austrians beaten off, thanks to Vendôme's opportune arrival and dauntless courage (battle of Cassano, August 16). Nevertheless, the subjugation of Piedmont was put off until the next year.

Ramillies, 1706.—1706 was a bad year for the French. At the very outset of the campaign in the Netherlands, Villeroy, hearing that some of the allied contingents that composed Marlborough's army had refused to join, ventured out from his new defensive lines along the Dyle and moved towards Namur. Marlborough hurried forward to intercept him before he could reach the shelter of the Meuse fortresses and was able (May 12) not only to win but also to profit by the glorious victory of Ramillies (*q.v.*) on the 12th of May.

In Italy the campaign had, as before, two branches, the contest for Piedmont and the contest between the French forces in Lombardy and the Austrian second army that sought to join Victor Amadeus and Starhemberg. The latter, repulsed by Vendôme at Cassano, had retired to Brescia and Lake Garda, Vendôme followed, and in April 1706, profiting by Eugene's temporary absence, attacked the Imperialists' camps. His onset broke up the defence completely (battle of Calcinato, April 19), and he hustled the fragments of the Imperialist army back into the mountains, where Eugene had the greatest difficulty in rallying them. Until the middle of June Vendôme completely baffled all attempts of Eugene to slip past him into Piedmont. He was then, however, recalled to supersede Villeroy in Belgium, and his feeble successor entirely failed to rise to the occasion. Philip of Orleans, with Marsin, was besieging Turin. As soon as he knew of Vendôme's departure Prince Eugene emerged afresh from the mountains, and, out-manoeuvring the French in Lombardy, hurried towards Turin. Victor Amadeus, leaving the defence to the Austrian and Piedmontese infantry, escaped through the besiegers' lines and joined his cousin with a large force of cavalry. On Sept. 7 they attacked the French lines round Turin. Owing to the disagreements of their generals, the various corps of the defenders, though superior in total numbers, were beaten in detail. Marsin was killed and Orleans retreated ignominiously to Pinerolo. The battle of Turin practically ended the war in Italy.

Both in the north and in the south the tide had now receded to the frontiers of France itself. But it is from this very point that the French operations cease (though only gradually it is true) to be the ill-defined and badly-joined patchwork of forays and cordons that they had hitherto been. In the place of Tallards, Marsins and Villeroys Louis made up his mind to put his Villars, Vendômes and Berwicks, and above all the approach of the allied armies roused in the French nation itself a spirit of national defence which bears at least a faint resemblance to the great uprisings of 1792. For the gathering of this unexpected moral force 1707 afforded a year of respite. Marshal Tessé formed a strong army for the defence of the Alpine frontier. In Germany Villars not only pricked the bubble reputation of the lines of Stollhofen, but raided into Bavaria, penetrating as far as Blenheim battlefield before he gave up the attempt to rouse the Bavarians again. The Imperialists and Piedmontese in the south succeeded in turning the Alpine barrier, but they were brought to a complete standstill by Tessé's gallant defence of Toulon (August) and finally retired over the mountains. In Belgium the elector of Bavaria, who was viceroy there for King Philip, and was seconded by Vendôme, remained quiescent about Mons and Gembloux, while Marlborough, paralysed more completely than ever before by the Dutch, spent the summer inactive in camp on the Gheete.

Campaign of 1708.—In 1708 Eugene foresaw this shift of the centre of gravity and arranged with Marlborough to transfer his army which was ostensibly destined for the Rhine campaign to Brabant, since the French was markedly superior in numbers to Marlborough's and hardly inferior to Marlborough's and Eugene's combined. King Louis had put his young grandson and heir, the duke of Burgundy, at the head of the great army which assembled at Valenciennes, and gave him Vendôme as mentor. But the prince was pious, mild-mannered, unambitious of military glory and also obstinate, and to unite him with the fiery, loose-living and daring Vendôme, was, as Saint-Simon says, "mixing fire and water." At the end of May Vendôme advanced to engage Marlborough before Eugene should join him. As the French came on towards Brussels, Marlborough, who had concentrated at Hal, fell back by a forced march to Louvain. Vendôme having thus won the first move, there was a pause and then the French suddenly swung round to the west, and began to overrun Flanders, where their agents had already won over many of the officials who had been installed by the allies since 1706. Ghent and Bruges surrendered at once, and to regain for King Philip all the country west of the Scheldt it only remained to take Oudenarde. On the day of the surrender of Ghent Marlborough was moving to interpose himself between the French and their frontier, and one long forced march brought his army almost within striking distance of the enemy. But though Eugene himself had joined him, Eugene's army was still far behind. Vendôme soon moved on Oudenarde. But scarcely had he begun this investment when Marlborough was upon him.

Oudenarde.—The duke discussed the situation with Eugene.

Marlborough was half inclined to wait for Eugene's troops, for he knew that Vendôme was no ordinary opponent, but Eugene counselled immediate action lest the French should escape, and relying on his own skill and on the well-known disunion in the French headquarters, Marlborough went forward. As he approached, the enemy gave up the siege of Oudenarde and took up a position at Gavre, 7 m. lower down the Scheldt. Here the dissensions in the French headquarters became flagrant. Vendôme began to place part of the army in position along the river while the duke of Burgundy was posting the rest much farther back as another line of defence. The allied main body, marching with all speed, crossed the Scheldt at all hazards. In the encounter-battle which followed (*see* OUDENARDE) Marlborough separated, cut off and destroyed the French right wing The French retreated in disorder on Ghent (July 11) with a loss of 15,000 men. Marlborough was prevented from carrying out his desire for a prompt move on Paris after Oudenarde. For the moment Berwick, recalled from Alsace, manoeuvred about Douay, while Vendôme remained near Ghent, and between them Marlborough's and Eugene's armies devoted themselves to the siege of Lille In this town, one of Vauban's masterpieces of fortification, the old Marshal Boufflers had undertaken the defence, and it offered a long and unusually gallant resistance to Eugene's army Marlborough covered the siege. The French generals limited their efforts first to attempting to intercept a huge convoy of artillery and stores that the allies brought up from Brussels for the siege, and secondly to destroy another convoy that was brought up from Ostend by the General Webb known to readers of *Esmond*. The futile attack upon the second convoy is known as the action of Wynendael (Sept. 28)

On Dec. 8 the brave old marshal surrendered, Eugene complimenting him by allowing him to dictate the terms of capitulation. Ghent and Bruges were retaken by the allies without difficulty, and, to add to the disasters of Oudenarde and Lille, a terrible winter almost completed the ruin of France In despair Louis negotiated for peace, but the coalition offered such hard terms that not only the king, but his people also, resolved to fight to the end.

1709, Malplaquet.—When spring came round Marlborough proposed to make a daring thrust toward Paris, masking the fortresses, but this scheme was too bold even for Eugene, who preferred to reduce the strong places before going on. Lille having been successfully besieged, Tournai was the next objective, and the allies suddenly and secretly left their camps before Lille as if for an attack on the Douai lines (June 26–27). But before noon on the 27th they had invested Tournai. A few days afterwards their siege guns came up from Menin by water (down the Lys and up the Scheldt) and the siege was pressed with intense vigour. But it was Sept. 3 before the citadel capitulated. Then Marlborough, free to move again, transferred his army secretly and by degrees to the river Haine, and burst through the French lines almost unopposed. Mons was weakly held, and Marlborough hoped by the rapidity of his operations to take it before Villars could interrupt him But Villars also moved quickly, and his eager army was roused to enthusiasm by the arrival of Boufflers, who, senior as he was to Villars, had come forward again at the moment of danger to serve as his second in command. Thinking that the allies were somewhat farther to the east than they were in fact, the French marshal marched secretly, screened by the broken and wooded ground, to the south of the fortress, and occupied the gap of Aulnois-Malplaquet (Sept 9) to work feverishly to entrench himself. Marlborough at once giving up the siege of Mons brought his army forward to attack as rapidly as his brigades came on the scene. At this crisis the duke submitted the question of battle—unwillingly, as one may imagine—to a council of war, and Eugene himself was opposed to fighting an improvised battle when so much was at stake, and it was not until the 11th that the duke delivered his attack on the now thoroughly entrenched position of the French. The battle of Malplaquet (*q.v.*) was by far the most desperately contested of the war. In the end Boufflers, who took command when Villars was wounded, acknowledged defeat and drew off in good order. Eugene was wounded, and Marlborough, after the most terrible experience in any soldier's lifetime, had only enough energy remaining to take Mons before he retired into winter quarters. The loss of the French is given variously as 7,000 and 12,000. The allies sacrificed no less, probably more, than 20,000 men.

Campaign of 1710.—In 1710 Villars lay entrenched behind a new series of lines, which he called *Ne plus ultra* and which extended from Valenciennes to the sea. Marlborough made no attempt to invade France from the side of Mons, for Villars at the head of the army which had been through the ordeal of Malplaquet was too terrible an opponent to pass by with impunity. In England, too, the anti-Marlborough party was gaining the upper hand in the queen's council. So Marlborough took no risks, and returning to the Lille side, captured Douai (June 26) and Béthune (Aug 26). No attack was attempted upon the lines. In Dauphiné, Berwick repulsed the Austrians and Piedmontese.

The year 1711 was Marlborough's last campaign, and it was remarkable for the capture of the *Ne plus ultra* lines by manoeuvres that must be recorded as being the *ne plus ultra* of the 18th century way of making war by stratagem In May the sudden death of the emperor completely altered the political outlook, for his successor Charles was the coalition's claimant to the throne of Spain, and those who were fighting for the "Balance of Power" could no more tolerate a new Charles V. than they could see Louis XIV. become a Charlemagne.

In accordance with a strategic policy of passive endurance the marshal Villars remained on the defensive behind his lines, and Marlborough determined to dislodge him. What force could not achieve, the duke trusted to obtain by ruse. The lines extended from the sea along the Canche, thence to Arras, and along the Sensée to Bouchain on the Scheldt. As the western part of the lines, besides being strong, were worthless from the invaders' point of view because their capture could not lead to anything, Marlborough determined to pass the barrier between Arras and Bouchain. On July 6 Marlborough marched away to the west, as if to attack the lines between Arras and the headwaters of the Canche Villars followed suit. The plot of the comedy now thickened. Marlborough lost his usual serenity, and behaved in so eccentric a manner that his own army thought him mad He sent off one part of his forces to Béthune, another back to Douai, and ordered the small remainder to attack the lines between the Canche and Arras, where, as every one knew, Villars's whole army was massed In the night of Aug. 4–5 the main army slipped off westward, at the highest possible speed The Scarpe was crossed and then the pace was increased, though thousands of the infantry fell out and scores died from exhaustion. Five hours ahead of the French army the allies crossed the great lines unresisted The troops concentrated at Cambrai when Marlborough, declining Villars's offer of a battle, manoeuvred still farther to the east and invested Bouchain The siege, covered by a strong "line of circumvallation" which Villars did not attempt to attack, ended with the surrender of the place on Sept. 13, and so terminated a series of manoeuvres so extraordinary as to be almost incredible In December Marlborough was dismissed the service in disgrace

But Holland and Austria determined to make one last effort to impose their own terms on Louis Eugene's army, which had been used in 1711 to influence the imperial election instead of to beat Villars, was brought back to the Low Countries. Reading the meaning of Marlborough's fall, he quietly made preparations to take over the various allied contingents into Imperial or Dutch pay. So when England seceded, Ormonde only marched away with 12,000 sullen men, while 100,000 remained with the prince.

Misfortunes at Versailles helped Eugene in his first operations, for two successive heirs apparent to the crown died within a month and all was in confusion, not to speak of the terrible misery that prevailed in the country But the old king's courage rose with the danger and he told Villars that if the army were beaten he would himself join it and share in its fate. Villars, though suffering still from his Malplaquet wound, took command on April 20, and spun out time on the defensive until the end of May, when Ormonde's contingent withdrew. Eugene, as the defection of England had made further operations near the sea unprofitable, took Le Quesnoy (July 4) and moved thence on to Landrecies, which was

closely invested. Then followed the last serious fight of the war, the battle of Denain, which saved the French monarchy and completed the disintegration of the coalition.

Denain.—In order to protect his camps around Landrecies, Prince Eugene constructed the usual lines of circumvallation with such speed that Villars, on coming up, found that they were too formidable to attack. Villars anxiously looked out for an opportunity of breaking through. At Denain, the besiegers' route crossed the Scheldt and he resolved to attack them there. The enterprise, like Marlborough's forcing of the *Ne plus ultra* lines, involved an extraordinary combination of force and fraud—for the point of attack was far away and the opposing army almost within cannon-shot. Some days were spent by Villars in deceiving Eugene and his own army as well, as to his real intentions. Then on the night of July 23 the French army moved off silently, and by 9 A.M. on the 24th had completely deployed on the north bank of the Scheldt. Eugene galloped away to bring up his army from Landrecies. But, long before it arrived, Villars's troops stormed the lines. A mass of Dutch troops—spiritless since Malplaquet—were huddled into the narrow avenue between the two entrenchments and forced back against a broken bridge. Their generals were taken. The broken mob of fugitives tamely surrendered. Eugene arrived on the other bank with some brigades of the imperial infantry, but failed to reopen the passage. Villars followed up his victory at once, capturing Marchiennes and St. Amand, and in these places all Eugene's reserve stores, pontoons and guns. On Aug. 2 Eugene broke up the siege of Landrecies and retreated by a roundabout route to Mons, while Villars's lieutenants retook Douai and Bouchain (September–October). Before next campaign opened the treaty of Utrecht had been signed, although the emperor continued the struggle alone for another the enfeebled combatants were content to accept Villars's res of Landau (July 22, 1713) and Freiburg (Nov. 21) as The treaty of Rastatt, between Austria and France, was n March 7, 1714, Eugene and Villars being the negotiators.

NAVAL OPERATIONS AND MILITARY OPERATIONS IN SPAIN

On the great campaigns fought in the Rhine delta and in North ly, often tend to obscure the fact that the principal objective both sides during the war was Spain. The French could reach the theatre of operations quite easily by land, but the Austrian Imperialists had to rely entirely on Anglo-Dutch fleets to make their efforts effective. On the formation of the Grand Alliance, considerable difference of opinion arose as to how the English fleet should be used, William III. and Marlborough being in favour of a concentration in the Mediterranean, while many of the sailors advocated oceanic operations on the Atlantic coast of Spain and Portugal, and on the east coast of America.

Allied Victory at Cadiz.—Admiral Sir George Rooke was put in command of the combined fleet, consisting of 30 English ships of the line, and 20 Dutch under Admiral van Almonde, and carrying 13,000 English and Dutch troops under the Duke of Ormonde. Rooke was instructed to seize Cadiz as a base for future operations in the Mediterranean. Inevitable complications, however, arose. It was judged inexpedient to compel the Spaniards to acknowledge the Archduke Charles as their rightful king, by means of a bombardment, and they, being not unnaturally somewhat backward in receiving the candidature of an Austrian Prince, lent no support to the Anglo-Dutch arms. Consequently the attempt on Cadiz could not be pushed too vigorously and may be said to have failed. Rooke was already steering north again when he learnt that the Spanish treasure fleet had entered Vigo Bay, protected by Admiral Châteaurenault with a French squadron. The Allies at once determined to prevent the French obtaining the treasure by capturing it themselves, and, entering the bay, Ormonde's troops were landed to attack the forts, while Rooke pushed forward a special advance squadron and forced the boom which the French had laid across the entrance to the inner harbour (Oct. 12, 1702). In the furious engagement which followed, Rooke sank and captured the 24 French warships and the 17 Spanish galleons, and recovered bullion worth two million pounds.

Portugal Joins Allies.—In 1703 Portugal joined the Allies so that Lisbon could be used as a naval base, but Admiral Clowdisley Shovell was sent to the Mediterranean too late to achieve any object, and many of his ships on their return were destroyed in the Channel during the great storm of Nov. 27. Great efforts were made in 1704 to bring about something decisive. Rooke sailed in February and landed the Archduke Charles at Lisbon, together with 2,000 English and Dutch troops to co-operate with the Portuguese in an invasion of Spain.

Rooke carried his fleet through the Straits, hoping to be able to make an attack on Toulon in concert with the duke of Savoy, who had recently joined the alliance. This, in conjunction with Marlborough's march across Germany to Blenheim, would have been a fine counterstroke to the French thrust at Vienna, but as often happened afterwards, Savoy failed to co-operate. An attempt was made to win over Barcelona to the archduke's cause, but the governor refused to admit the allied forces. Meanwhile, the Comte de Toulouse succeeded in bringing the French Brest fleet into the Mediterranean and though Rooke sighted him, his ships were too foul to catch the French, who entered Toulon unopposed, and so united their principal Atlantic and Mediterranean forces. Rooke therefore passed the Straits and met Shovell and the Dutch between Cape St. Vincent and Cadiz, and then re-entered the Mediterranean to watch for the French.

Gibraltar Taken by Allies.—At this juncture the allied leaders took the memorable decision to capture Gibraltar and so advance their sphere of activity 300 miles beyond Lisbon. After lengthy preparations the attack was begun by Admiral George Byng, who bombarded the fortress with a special squadron on July 23 (1704), while Prince George of Hesse-Darmstadt, the Imperial representative, landed 1,800 English marines and cut off the fortress on the land side. Gibraltar being only weakly held, an attacking force was soon landed from the ships, and the place surrendered next day.

Hardly was this great success achieved than Toulouse was reported sailing south-west to recapture the fortress. Rooke left Prince George and 900 marines in Gibraltar and went in search of Toulouse, having had to spend some time watering his fleet at Tetuan. On Aug. 9 the fleets were in sight of each other, but the French retreated and then attempted to double back again close inshore. Rooke, however, sighted them slipping past and brought them to action off Malaga on Aug. 13, each side having about 50 ships of the line. The French were decisively beaten.

The allies returned to Lisbon to refit, leaving Prince George with all the marines and some ships, guns and stores to defend Gibraltar. He was soon attacked by land and sea in overwhelming force, but was relieved by Admiral Leake, who arrived from Lisbon where he had been left in command by Rooke, who had gone home. Entering the bay on Oct. 25, the day on which the final attack was to take place, he destroyed the French flotilla, enfiladed the Franco-Spanish entrenchments on shore, and revictualled and reinforced the garrison. The French now sent Marshal Tessé with a siege train to command the attack by land, and Prince George was again hard pressed, but Leake again reinforced and revictualled him in December. At last, on March 10, 1705, Leake destroyed de Pointis' force at Marbella, and Tessé raised the siege.

Allies Invade Spain.—The Allies now took the offensive, Shovell and Lord Peterborough coming out from England as joint commanders. Picking up Leake at Lisbon and Prince George at Gibraltar, they sailed to Barcelona and besieged it. It was finally captured and occupied on Oct. 3, 1705, but Prince George was killed during the assault. Philip, the Bourbon candidate, hurried to Catalonia with Marshal Tessé to recapture it, and a squadron put out from Toulon. Leake, however, was able to foil all the French efforts and forced them to raise the siege on April 30, 1706.

PICTURES TAKEN BY SPARK PHOTOGRAPHY

1. Spark photograph of gun muzzle before bullet has emerged
2. Photo of same gun muzzle. Bullet cannot be seen on account of propelling charge
3. Showing the bullet, a .30 calibre Springfield, only 11 in. from the muzzle of the gun, yet it has already outdistanced the outermost effect of the propelling charge
4. Muzzle of a Thompson sub-machine gun fitted with Cutts compensator; bullet and propelling charge emerging from barrel
5. Another view of machine gun. Bullet shown in fig. 4, seen at right between puffs of emerging smoke, some of which escapes through slots in top of compensator attached to muzzle of gun (left)

Leake, who was again left in command of the fleet, made good use of his time by capturing Cartagena (June 1, 1706) and Alicante (Aug. 24, 1706), and then sailing to the Balearic Islands and capturing Mallorca (Majorca) and Iviza in September.

Meanwhile, the allied troops advanced from Portugal and captured Madrid (June 26, 1706) and proclaimed the archduke Charles. The Castilians, however, did not relish invasion by the Portuguese, and being rallied by Berwick, compelled the allies to retreat south-east to Valencia, on the coast.

Closing Operations.—In July and August combined operations were again attempted against Toulon, but again Savoy defaulted, and Shovell, returning with 12 of the line, was wrecked on the Scilly Isles on Oct. 22, 1707, together with several other ships which were lost with all hands. Leake now exercised the permanent command-in-chief and operated in the Mediterranean with great success, reducing Sardinia for the Imperialists in August 1708. In September General Stanhope captured Minorca.

The war in Spain languished owing to the increasing exhaustion of both sides and the apathy of the Spaniards. Stanhope, however, in 1710 persuaded the Imperialist troops to join him in another invasion, and they actually succeeded in bringing the archduke Charles to Madrid. Previous conditions, however, reasserted themselves, and the allies were again driven east to the coast by the duc de Vendôme, the new general of the Franco-Spanish forces. Stanhope was defeated and captured on Dec. 9, 1710 at Brihuego, and the Imperialists were only just able to make good their retreat to Barcelona, which they held till the Peace of Utrecht, though the Catalans themselves heroically defended it against Berwick till Sept. 12, 1714 At sea, Admiral Wager captured a Spanish treasure fleet off Cartagena in May 1708, and Duguay Trouin captured an English convoy off the Lizard on Oct. 20. In 1710 Commodore Martin's squadron, assisted by American Colonists, captured Nova Scotia

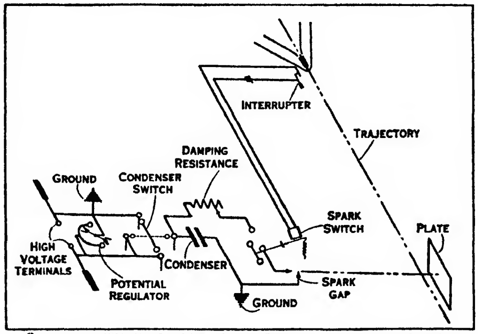
SPANNER is a tool for turning nuts, setscrews, coachscrews, spindles, including those of hydrants and valves The principal forms are the *straight* spanners, single-ended or double-ended, the *angle,* which enables a nut to be turned in a confined space, and the *box* spanners enabling the nut to be readily turned from above or from the side, without slip. Tubular box spanners are light and strong, being suited for portable sets. The *structural* spanner has a long handle terminating in a tapered end. This is used to pull holes into line in erecting bridges and other structures, and when not in use the end is stuck into any convenient hole, ready to hand for the next usage. The *platelayer* or *track* spanner is also very long, but with parallel handle; it gives great power for dealing with fish-plate bolts. The *pin* and the *hook* spanners turn circular nuts, the one with a pin entering a drilled hole on the nut, the other a hook catching in a slot. The *cap wrench* or *axle-spanner* grips on four surfaces of a road wheel nut A *ratchet* wrench enables nuts to be manipulated with a short stroke of the handle, for rapid working. In big repair shops and the automobile and other factories power-operated spanners are employed for quick loosening and tightening.

SPARK PHOTOGRAPHY, in which the illumination is provided by an electric spark of such short duration that even the most rapidly moving objects appear stationary, has many applications in the investigation of high speed phenomena. The record obtained is not an image, no lens being used, but is simply the silhouette of objects between the light source and the photographic plate. In order to secure a properly timed spark of suitable character there must be available a means of generating electrical energy at very high voltage, a means of storing such energy, apparatus for the regulation of the voltage at the proper time. The manner in which these components are associated is shown in the accompanying diagram.

The operation of the apparatus, which is all set up in a dark room, is as follows: Having put the film or plate in place, the operator sets the spark switch and starts the generator. The condensers, when charged, are automatically disconnected from the generator and a signal light is turned on as soon as the potential across them reaches the magnitude at which the regulator is set to function. The gun is then fired immediately When the sound wave from the bullet or the propelling charge, according to circumstances, impinges upon the diaphragm of the interrupter, the electric circuit to the spark switch is momentarily opened. The



Schematic Wiring Diagram of Spark Photography Apparatus

switch arm then closes the so-called trigger gap at such time as the bullet or shot being photographed has arrived in front of the photographic plate. As the trigger gap is closed, the condensers discharge through the trigger gap, spark gap and damping resistance which are all connected in series. If the spark lasts while the bullet moves appreciably blurring will result. Since the spark discharge from a condenser is not of itself of the proper character, the so-called damping resistance is introduced in the spark circuit. In this way a single spark of great brilliance and lasting for only one or two millionths of a second is obtained.

Some idea of the accuracy of the equipment may be obtained from the fact that as many as 80 consecutive shot shells have been photographed in one lot without a single failure.

Applications to Ballistics.—There is, perhaps, no question in the realm of the ballistics of small arms upon which there has been so great a diversity of opinion as that of acceleration of a projectile after leaving the muzzle of the gun; this effect has been supposed by some authorities to exist "at points from 20 to 30 ft in advance of the muzzle." Plate II, fig. 3, shows the bullet of a .30 calibre Springfield rifle. In this photograph the bullet is out 11 in. from the muzzle and yet it has already out-distanced the outermost effect of the propelling charge.

No bullet is absolutely gas tight and figures show the gas which has leaked past the bullet while still in the barrel. Plate I, fig. 5, shows the .45 calibre Colt automatic pistol. Similar photographs show that no upward tilting of the muzzle occurs until the bullet is several feet from the muzzle. That is to say the so-called kick in no way affects the accuracy. Plate I., fig. 3 shows a modified 30 calibre bullet after passing through a soap bubble filled with a mixture of hydrogen and air which produces the distortion in the sound waves shown. Plate I, fig. 4 shows a steel ball after falling into a soap bubble which closed after it. Note small bubble between ball and top of film. Plate II., fig. 4 and 5 shows the muzzle of a .45 calibre Thompson sub-machine gun with the Cutt's compensator attached (P Q.)

SPARK or **SPARKING-PLUG:** *see* Internal Combustion Engine and Motor Cars.

SPARKS, JARED (1789–1866), American historian and educator, was born in Willington (Conn.), on May 10, 1789. He made a brilliant record in his studies and after labouring as a carpenter and teaching at a country school he graduated at Harvard in 1815. Private school teaching and a tutorship in mathematics and natural philosophy at Harvard were but incidents in his career. He refused a professorship at Bowdoin college for the pastorate of a Unitarian church in Baltimore. In 1821 he founded

The Unitarian Miscellany, and was chosen chaplain of the national House of Representatives, where he made many influential friends. Probably his natural bent towards writing as well as the state of his health was responsible for his leaving the ministry in 1823 and purchasing the *North American Review*, of which he had been acting editor in 1817–18 and which he edited until 1830. This periodical by good management he made a financial success and the arbiter of literature in New England. But although he founded *The American Almanac and Repository of Useful Knowledge* in 1830, the major portion of his energy after 1826 was devoted to historical scholarship. Born in the shadow of the great figures of the Revolution, he did his most important work in *The Life and Writings of George Washington* (12 vols., 1834–37) and *The Works of Benjamin Franklin; with Notes, and a Life of the Author* (10 vols., 1836–40). Another valuable project was *The Library of American Biography* (first series, 10 vols., 1834–38; second series, 15 vols., 1844–47), which he edited and to which he contributed a number of lives. Of lesser value are the *Life and Travels of John Ledyard* (1828); *The Diplomatic Correspondence of the American Revolution* (12 vols., 1829–30); *The Life of Gouverneur Morris* (3 vols., 1832); and *Correspondence of the American Revolution, being Letters of Eminent Men to George Washington* (1853). The esteem in which he was held in his day is shown not only by the large sale of his works but by his appointment in 1838 to the first American professorship of history at Harvard, and by his election to the presidency of that college in 1849. After his retirement in 1853 he lived quietly in Cambridge until his death on March 14, 1866.

See H. B. Adams, *The Life and Writings of Jared Sparks* (2 vol., 1893) and J. S. Bassett, *The Middle Group of American Historians* (1917).

SPARROW, a word originally meaning any small bird, now restricted to those of the types enumerated below.

(1). The house sparrow (*Passer domesticus*) is "the sparrow" *par excellence*. Thriving best in the neighbourhood of man, this bird is common throughout the northern parts of Europe and Asia and has been introduced into North America (in 1851) and the British colonies.

(2). The tree sparrow, or mountain sparrow (*P. montanus*), both sexes of which resemble the male house sparrow, but are distinguished by the rufous crown and doubly barred wings, is a local species in England. In China, it is abundant and replaces the house sparrow near houses and in towns.

(3). The hedge sparrow or dunnock (*Prunella modularis*), belonging to the thrushes (*q.v.*), is a little brown-backed bird with an iron grey head and neck. It is widely distributed throughout Europe.

(4). The reed-sparrow or reed-bunting is, as the second name implies, a bunting (*q.v.*).

(5). The numerous American sparrows are also buntings (*q.v.*). Among them may be mentioned the song sparrow (*Melospiza melodia*) of which about 20 sub-species are recognized. It has a fine song. The chipping sparrow (*Spizella passerina*) is a confiding, humble little bird, with no great attractions but his manners. The savannah sparrow (*Passerculus sandwichensis*) is abundant in the maritime provinces of Canada, but breeds south to Iowa. The grasshopper sparrow (*Ammodramus savannarum*) is also a common form, but its skulking habits and insect-like notes cause it to be overlooked. The lark sparrow (*Chondestes grammacus*) is common in the Mississippi valley east of the great plains; it has a pleasant if hurried song. The fox-sparrow (*Passerella iliaca*) has also a fine song; it breeds in north Canada and Alaska, wintering from Ohio southward.

SPARTA (Gr. Σπάρτη or Λακεδαίμων), an ancient city in Greece, the capital of Laconia and the most powerful state of the Peloponnese. The city lay at the N. end of the central Laconian plain, on the right bank of the Eurotas, S. of its junction with the Oenus (mod. Kelefína), commanding the only land-routes into Laconia, the Oenus and Eurotas valleys from Arcadia, and the Langáda Pass over Mt. Taygetus from Messenia. At the same time its distance (27 m. from its port, Gythium) made it invulnerable from the sea.

ARCHAEOLOGY

Until 1905 the visible ancient buildings at Sparta were the theatre, the "Tomb of Leonidas," a quadrangular building of immense blocks containing two chambers; the foundation of a bridge over the Eurotas; a curved structure since found to be a Hellenic retaining wall restored in Roman times, and some late Roman fortifications, buildings and mosaic pavements. Inscriptions, sculptures and other objects were collected in the museum, or built into houses or churches. Excavations were carried on near Sparta, on the site of the Amyclaeum (1890 Tsountas, 1904 Furtwängler) at the shrine of Menelaus in Therapne (1833, 1841, Ross; 1889, 1900, Kastriotis) and at the "round building" (1892 and 1893 American School at Athens). But no organized work was tried in Sparta itself.

Systematic exploration, however, began with the excavations of the British School at Athens, at Thalamae, Geronthrae, and Angelona near Monemvasia, in 1904, and at Sparta itself in 1906. A "small circus" described by Leake, was found to be a theatre-like building constructed soon after A.D. 200 round the altar and in front of the temple of Artemis Orthia. Here musical and gymnastic contests took place as well as the famous flogging-ordeal (*diamastigosis*). The temple, of the 2nd century B.C. overlies an older temple of the 6th century, and close beside it were found remains of a yet earlier temple, dating from the 9th or even the 10th century. The votive offerings in clay, amber, bronze, ivory and lead found in profusion within the precinct range from the 9th to the 4th century B.C.; they prove that Sparta reached her artistic zenith in the 7th century and declined in the 6th. In 1907 the sanctuary of Athena "of the Brazen House" (Χαλκίοικος) was found on the Acropolis immediately above the theatre, and though the temple is destroyed, fragments of capitals in Doric style remained; also the longest extant archaic inscription of Laconia, and numerous bronze nails, plates and votive offerings of great interest. The Greek city-wall, built in stages from the 4th to the 2nd century, has a circuit of nearly 6 m. (Polyb. ix. 21). The late Roman wall enclosing the Acropolis, probably dates from the years following the Gothic raid of A.D. 262. A number of points of Spartan topography, have been fixed in accord with the description of Pausanias. In 1910 the town of the "Mycenean" period on the left bank of the Eurotas a little to the S.E. was found to be roughly triangular, with an area approximately equal to that of Sparta, but nothing is left but foundations and potsherds. More recently, excavation of the theatre has yielded, besides inscriptions and small objects, a remarkable fifth century statue of a warrior.

HISTORY

Prehistoric Period.—Tradition relates that Sparta was founded by Lacedaemon, son of Zeus and Taygete. But Amyclae and Therapne (Therapnae) were in early times of greater importance than Sparta, the former a Minyan foundation a few miles to the south of Sparta, the latter the Achaean capital of Laconia and the seat of Menelaus. Eighty years after the Trojan War, according to the traditional chronology, the Dorian migration took place (*see* GREECE; *History* [*Ancient*]). A band of Dorians (*q.v.*) united with a body of Aetolians to cross the Corinthian Gulf and invade the Peloponnese from the north-west. The Aetolians settled in Elis, the Dorians pushed up to the headwaters of the Alpheus, where they divided into two forces, one of which, under Cresphontes, subdued Messenia, while the other, led by Aristodemus, made its way down the Eurotas valley and gained Sparta, which became the Dorian capital of Laconia. In reality this Dorian immigration probably consisted of a series of inroads and settlements rather than a single expedition. The newly founded state did not at once become powerful: the turning-point is marked by the legislation of Lycurgus (*q.v.*), who instituted that training which was its distinguishing feature and the source of its greatness. Nowhere else was the individual so thoroughly subordinated to the interest of the state. The whole education of the Spartan was designed to make him an efficient soldier. Obedience, endurance, military success—these were the aims constantly kept in view, and all other ends took a secondary place.

The Expansion of Sparta.—The first step in the reign of

Archelaus and Charillus, was to secure the upper Eurotas valley, conquering the border territory of Aegys. Archelaus's son Teleclus is said to have taken Amyclae, Pharis and Geronthrae, mastering the central Laconian plain and the eastern plateau between the Eurotas and Mt. Parnon; his son, Alcamenes, by the subjugation of Helos, brought the lower Eurotas plain under Spartan rule. About this time, the Argives, whose territory included the whole east coast of the Peloponnese and the island of Cythera (Herod. i 82), were driven back, and the whole of Laconia was incorporated in the Spartan state. Under Alcamenes and Theopompus a war broke out between the Spartans and the Messenians, which, after 20 years, ended in the capture of Ithome and the subjection of the Messenians, who were forced to pay half the produce of the soil as tribute. An attempt to throw off the yoke resulted in a second war, conducted by the Messenian hero Aristomenes (*q v*); but Spartan tenacity prevailed, and Messenia was made Spartan territory, its people being reduced to the status of helots (*q.v*).

This extension of Sparta's territory was viewed with apprehension by her neighbours in the Peloponnese. Arcadia and Argos had vigorously aided the Messenians in their two struggles; only the Corinthians supported the Spartans, doubtless through jealousy of their neighbours, the Argives. At the close of the second Messenian War (*c.* 631 B.C.) no power could hope to cope with that of Sparta save Arcadia and Argos. In the 6th century Sparta made a vigorous attack on Tegea, the most powerful of the Arcadian cities, but it was not until the middle of the century that Tegea was forced to acknowledge Spartan overlordship, though retaining its independence. The final struggle for Peloponnesian supremacy was with Argos; but Argos was now no longer at the height of its power; it could not count on the assistance of Arcadia and Messenia, since the latter had been crushed and the former had acknowledged Spartan supremacy. A victory, won about 546 B C., made the Spartans masters of the Cynuria, the borderland between Laconia and Argolis. The final blow was struck by King Cleomenes I. (*q v*), and left Sparta without a rival in the Peloponnese. By the middle of the 6th century, Sparta had come to be acknowledged as the leading state of Hellas and the champion of Hellenism. Croesus of Lydia had formed an alliance with her; to her the Greeks of Asia Minor appealed to withstand the Persian advance and to aid the Ionian revolt; Plataea asked for her protection; and at the time of the Persian invasion under Xerxes (*see* GRAECO-PERSIAN WARS) no state questioned her right to lead the Greek forces on land and sea. Of such a position Sparta proved herself unworthy. She could never rid herself of her Peloponnesian outlook sufficiently to throw herself heartily into the affairs of the greater Hellas She was not a colonizing State, and had no share in the expansion of Greek commerce and Greek culture. Her military greatness formed her sole claim to lead the Greek race; that she should truly represent it was impossible.

Constitution.—Of the internal development of Sparta down to this time but little is recorded. This was attributed to the stability of the Spartan constitution, but it is, in fact, due also to the absence of historical literature at Sparta, to the small part played by written laws, expressly prohibited by an ordinance of Lycurgus, and to the secrecy of oligarchical rule. At the head of the state stood two hereditary kings, of the Agiad and Eurypontid families, equal in authority, though the Agiad king received greater honour in virtue of the seniority of his family (Herod. vi. 51, 52). This dual kingship was explained by the tradition that on Aristodemus's death he had been succeeded by his twin sons. Aristotle describes the kingship at Sparta as "a kind of unlimited and perpetual generalship" (*Pol.* iii. 1285*a*). Here also, however, the royal prerogatives were curtailed; the king lost the right of declaring war, was accompanied to the field by two ephors, and was supplanted by the ephors in the control of foreign policy. The kings became mere figure-heads, and the real power was transferred to the ephors and to the gerousia (*q.v.*). In the powers exercised by the assembly of the citizens or apella (*q.v.*) we cannot trace any development, owing to the scantiness of our sources. The Spartan was essentially a soldier, trained to obedience and endurance; he became a politician only if chosen as ephor for a single year or elected a life member of the council after his 60th year had brought freedom from military service.

Training of Citizens.—Shortly after birth the child was brought before the elders, who decided whether it was to be reared; if defective or weakly, it was exposed. Until their seventh year boys were educated at home; from that time their training was undertaken by the state and supervised by the παιδονόμος. This training consisted for the most part in physical exercises, with music and literature occupying a subordinate position From the 20th year began the Spartan's liability to military service and his membership of one of the ἀνδρεῖα or φιδίτια (dining messes or clubs), to which every citizen must belong At 30 began the full citizen rights and duties. Three conditions were requisite Spartiate birth, the training prescribed by law, and participation in one of the dining-clubs Those who fulfilled these conditions were the ὅμοῖοι (peers), those who failed were called ὑπομείονες (lesser men), and retained only the civil rights of citizenship.

Social System.—Spartiates were debarred by law from trade or manufacture, which rested in the hands of the perioeci (*q v.*), and were forbidden to possess either gold or silver, the currency consisting of bars of iron. Wealth was, in theory, derived entirely from landed property, and consisted in the annual return made by the helots, who cultivated the plots of ground allotted to the Spartiates. But this attempt to equalize property proved a failure; from early times there were marked differences of wealth within the state, and these became greater after the law of Epitadeus removed the legal prohibition of the gift or bequest of land The number of full citizens, 8,000 at the beginning of the 5th century, had sunk by Aristotle's day to less than 1,000, and had further decreased to 700 in 244 B.C.

The Persian Wars and After.—The beginning of the 5th century B C. saw Sparta at the height of her power; but after the Persian Wars the Spartan supremacy could no longer remain unchallenged. Sparta despatched an army in 490 B C to aid Athens in repelling the armament sent against it by Darius. But it arrived after the conflict had been decided at the battle of Marathon. In the second campaign Sparta assumed the command of the combined Greek forces by sea and land. Yet, in spite of the heroic defence of Thermopylae by Leonidas (*q v.*) the glory of the decisive victory at Salamis (*q v*) fell in great measure to the Athenians, and their patriotism and energy contrasted strongly with the hesitation of the Spartans and their selfish policy of defending the Peloponnese only. By the battle of Plataea (479 B C.), won by a Spartan general, the state partially recovered its prestige, but only so far as land operations were concerned; the victory of Mycale, won in the same year, was achieved by the united Greek fleet, and the capture of Sestos, which followed, was due to the Athenians. The perils and the glories of the Persian War were left to Athens, who, though at the outset merely the leading state in a confederacy of free allies, soon began to make herself the mistress of an empire. Sparta for a time took no steps to prevent this. Moreover, Sparta's attention was occupied by troubles nearer home—the plots of Pausanias not only with the Persian king but with the Laconian helots; the revolt of Tegea (*c.* 473–471); the earthquake which in 464 devastated Sparta; and the rising of the Messenian helots, which immediately followed. The insulting dismissal of Athenian troops which had come to aid the Spartans in the siege of the Messenian stronghold of Ithome, the consummation of the Attic democracy under Ephialtes and Pericles (*q.v.*), and the conclusion of an alliance between Athens and Argos united with other causes to bring about a rupture between the Athenians and the Peloponnesian League. In the so-called first Peloponnesian War Sparta herself took but a small share beyond helping to defeat the Athenians at Tanagra in 457 B C.

Peloponnesian War.—A fresh struggle, the great Peloponnesian War (*q.v.*), broke out in 431 B C. This may be to a certain extent regarded as a contest between Ionian and Dorian, or between the democratic and oligarchic principles of government; but at bottom its cause was neither racial nor constitutional, but economic. The maritime supremacy of Athens was used for commercial purposes, and important members of the Peloponnesian

confederacy, whose wealth depended largely on their commerce, notably Corinth and Megara, were being slowly but relentlessly crushed. Sparta remained unaffected, but she was forced to take action by the pressure of her allies. She did not prosecute the war with any vigour: her operations were almost confined to an annual inroad into Attica, and when in 425 B.C. a body of Spartiates was captured by the Athenians at Pylos, she was anxious to terminate the war on any reasonable conditions. That the terms of the Peace of Nicias (421), were rather in favour of Sparta than of Athens was due almost entirely to an individual Spartan, Brasidas (*q.v.*). The final success of Sparta and the capture of Athens in 405 were brought about partly by the treachery of Alcibiades. Funds were gained by subsidies from Persia, and Sparta found in Lysander (*q.v.*) an admiral of boundless vigour.

Spartan Empire.—The fall of Athens left Sparta once again supreme in the Greek world and demonstrated clearly her total unfitness for rule. Everywhere democracy was replaced by a philo-Laconian oligarchy, under a Spartan harmost or governor, and even in Laconia itself the narrow and selfish character of the Spartan rule led to a serious conspiracy. Under the energetic rule of Agesilaus, it seemed as if Sparta would pursue a Hellenic policy and carry on the war against Persia. But troubles soon broke out in Greece, Agesilaus was recalled from Asia Minor, and his schemes and successes were rendered fruitless. Further, the naval activity displayed by Sparta during the closing years of the Peloponnesian War abated when Persian subsidies were withdrawn. In 394 B.C. the Spartan navy under Peisander was defeated off Cnidus by the Persian fleet under Conon and Pharnabazus, and Sparta ceased to be a maritime power. In Greece itself, meanwhile, the opposition to Sparta was growing increasingly powerful, and the Spartans felt it necessary to rid themselves of Persian hostility. They therefore concluded with Artaxerxes II. the humiliating Peace of Antalcidas (387 B.C.), by which they surrendered to the Great King the Greek cities of the Asia Minor coast and of Cyprus. After a desultory war with Thebes over the independence of the Boeotian towns, the citadel of Thebes was treacherously seized by Phoebidas in 382 and held by the Spartans until 379 B.C. In 371 a fresh peace congress was summoned at Sparta. Again the Thebans refused to renounce their Boeotian hegemony, and the Spartan attempt at coercion ended in the defeat of the Spartan army at the battle of Leuctra and the transfer of the Greek supremacy from Sparta to Thebes.

Decline of Sparta.—In the course of three expeditions to the Peloponnese, conducted by Epameinondas (*q.v.*), the greatest soldier and statesman Thebes ever produced, Sparta was weakened by the loss of Messenia and by the foundation of Megalopolis as the capital of Arcadia. On Epameinondas's fourth expedition Sparta was again within an ace of capture, but the danger was averted; and though at Mantineia (362 B.C.) the Thebans, together with the Arcadians, Messenians and Argives, gained a victory over the combined Mantinean, Athenian and Spartan forces, yet the death of Epameinondas in the battle more than counterbalanced the Theban victory. But Sparta had neither the men nor the money to recover her lost position, and the continued existence on her borders of an independent Messenia and Arcadia kept her in constant fear for her own safety. No Spartiate fought on the field of Chaeroneia (338 B.C.). After the battle, however, she refused to submit voluntarily to Philip of Macedon, and was forced to do so by the devastation of Laconia and the transference of certain border districts to the neighbouring states of Argos, Arcadia and Messenia. During the absence of Alexander the Great in the East, Agis III. revolted, but the rising was crushed by Antipater, and a similar attempt after Alexander's death was frustrated by Demetrius Poliorcetes in 294 B.C. Twenty-two years later the city was attacked by Pyrrhus (*q.v.*), but the formidable enemy was repulsed. About 244 B.C. an Aetolian army overran Laconia, carrying off, it is said, 50,000 captives.

Attempts at Social Revolution.—This and other ignominious defeats of Sparta showed that she had shared, but in an unusual degree, in the general decay of Greece. On the accession of Agis IV. (*q.v.*) in 244 B.C. the citizen body had by the concentration of wealth in a few hands shrunk to a few hundred: the rest of the inhabitants were in their debt and their power. The Lycurgan constitution was ignored and Phylarchus (Plutarch's chief authority) gives us the usual picture of luxury and degeneracy. Agis by popular agitation was able to carry a resolution through the apella for a restoration of the Lycurgan discipline, together with a redivision of lands and a cancellation of debt. His fellow-king Leonidas opposed, but a section of the wealthy landowners, led by Agis's uncle Agesilaus, were in favour of a cancellation of debts, especially mortgages. With their assistance Agis was able to conciliate the ephors, remove Leonidas and replace him by his son-in-law Cleombrotus. The land was to be divided into "an inner ring about Sparta of 4,500 Spartan lots, and that in the outer ring into 15,000 lots for Perioeci; as there were nothing like 4,500 Spartans he proposed to fill up the number from Perioeci and selected metics in sympathy with Spartan institutions" (W. W. Tarn in *The Hellenistic Age*, 1923, p. 134). Agesilaus persuaded him to divide his programme into two halves, the cancellation of debts being carried through first. Immediately after this measure had been passed, Agesilaus with the other ephors sent Agis north with an army to assist the Achaean league against the Aetolian league. During his absence the two sections of the wealthy class reunited and the division of lands was prevented. Cleombrotus was expelled and Agesilaus brought back Leonidas. Agis on his return declined to use force to prevent the reaction directed by the Ephorate, took sanctuary and was killed by a trick. To prevent a recurrence of a social revolution, Leonidas forcibly married Agis's widow to his son Cleomenes, who was, however, converted by his wife and the Stoic Sphaerus to Agis's views. Thirteen years after Agis's death he came to the throne as Cleomenes III. (*q.v.*). He picked a quarrel with the Achaean league in order to be sent out in command of mercenaries, returned to Sparta, killed 14 of his opponents and exiled eighty. He carried through the division of land as contemplated by Agis (reserving 80 lots for the exiles), cancelled debts, and withdrew all the ephors' chairs except one, which he occupied himself. His war with the Achaean league now became a series of sensational victories, but the league finally secured the aid of Antigonus of Macedonia who forced Cleomenes to flee to Egypt.

Sparta fell back into its previous abject condition, until the rise of the tyrant Nabis, of whom we have only extremely hostile accounts. He abolished debts, redistributed land, taxed the wealthy heavily for the expense of the Lycurgan common meals, and extended the scope of the revolution by liberating helots. His stern reign is marked by another sudden renaissance of Sparta's military power: Sparta was indeed the only Greek power which was able to resist the legions of Flamininus the conqueror of Macedon. Flamininus failed to capture Sparta and in his final settlement left Nabis undisturbed in Laconia, though not in Argos. The experiment was brought to an end by the assassination of Nabis by the Aetolians: in the ensuing confusion Philopoemen (*q.v.*) the general of the Achaean league captured the city, destroyed the Lycurgan constitution of Nabis, and attached the state to the Achaean league. By his dexterity he was able to frustrate later attempts at revolution; and after the annexation of Greece by Rome Sparta has no history worth recording.

Mediaeval Sparta.—In A.D. 396 Alaric (*q.v.*) destroyed the city and at a later period Laconia was invaded and settled by Slavonic tribes. The Franks, on their arrival in the Morea, found a fortified city named Lacedaemonia occupying part of the site of ancient Sparta, and this continued to exist, though greatly depopulated, even after Guillaume de Villehardouin had in 1248–49 founded the fortress and city of Misithra, or Mistra, on a spur of Taygetus some three miles north-west of Sparta. This passed shortly afterwards into the hands of the Byzantines, who retained it until the Turks under Mohammed II. captured it in 1460. In 1687 it came into the possession of the Venetians, from whom it was wrested in 1715 by the Turks.

The Modern City.—In 1834, after the War of Independence, the modern town of Sparta was built on the ancient site from the designs of Baron Jochmus, and Mistra decayed until now it is almost deserted. Sparta is the capital of the prefecture (**νομός**)

of Lacedaemon. Pop (1923) 6,648.

SPARTACUS, leader in the Gladiatorial War against Rome (73–71 B C), a Thracian by birth He served in the Roman army, but seems to have deserted, for we are told that he was taken prisoner and sold as a slave. Destined for the arena, he, with a band of his fellow-gladiators, broke out of a training school at Capua and took refuge on Mt. Vesuvius (73), where they were joined by other runaway slaves They defeated two Roman forces in succession, and by the end of the year were 90,000 strong, and in possession of most of south Italy. The next year both consuls were sent against them, Spartacus defeated both of them, and fought his way successfully to the Alps. But the slaves refused to leave Italy, and after a half-hearted move towards Rome, they returned to Lucania. Eventually his large army divided, the Gauls and Germans were first defeated, and Spartacus, after successfully fighting in the retreat, fell fighting in a pitched battle (71), and the revolt was over. A large body of the slaves who escaped northwards were cut to pieces by Pompey on his way home from Spain. Spartacus was both competent and, apparently, humane His reputation has suffered from the terror his name inspired throughout Italy.

The story has to be pieced together from the vague and somewhat discrepant accounts of Plutarch (*Crassus,* 8–11; *Pompey,* 21), Appian (*Bell civ,* i 116–120), Florus (ii. 8), Livy (*Epit.* 95–97), and the fragments of the *Histories* of Sallust, whose account seems to have been full and graphic.

SPARTANBURG, a city of South Carolina, U S A, the county seat of Spartanburg county; in the north-western part of the State, on Federal highways 29 and 176. It is a station on the air-mail route from New York to Atlanta, and is served by the Charleston and Western Carolina, the Clinchfield, the Southern, and the Piedmont and Northern railways. Pop 22,638 in 1920 (35% negroes); estimated locally at 33,000 in 1928, with an additional 11,000 in the immediate suburbs. It is 875 ft above sea-level, in the heart of the beautiful Piedmont section, a leading theatre of industrial development in the South, and is one of the large textile centres of the country. It is the seat of Wofford college for men (Methodist Episcopal; 1850), Converse college for women (1889), and the Textile Industrial Institute (estab. 1911) whose students spend alternate weeks in the classroom and in the local textile mills. The city has seven cotton mills, with a total of 304,088 spindles and 7,712 looms (1928) Spartanburg has also large fertilizer plants, cottonseed-oil mills, and other manufacturing industries. It is an important distributing point for Northern manufacturers, and has a large wholesale and retail trade. Bank debits in 1927 aggregated $179,-181,000. Since 1913 the city has had a commission-manager form of government. Spartanburg was founded in 1787 and incorporated as a city in 1831.

SPARTEINE, one of the few liquid alkaloids (*see* ALKALOIDS) was isolated by Stenhouse (1852) from broom tops. Sparteine, $C_{15}H_{26}N_2$, boils at 325° C, has a specific rotation $[\alpha]^D$-16·42°, and is a strong base, forming salts which are difficult to crystallize owing to their ready solubility in water. Knowledge of the constitution of sparteine is principally due to Moureu and Valeur, who have assigned to it a constitutional formula which represents it as containing two quinuclidine nuclei and so brings it into relationship with the cinchona alkaloids (*see* CINCHONA). It resembles coniine (*q.v*) in physiological action.

SPARTINA. A genus of grasses (Gramineae) belonging to the tribe Chlorideae. Of the seven or eight species, most are North American, where the Fox grass (*S. patens*) and Salt Thatch (*S. alterniflora*) are common on the salt marshes of New England. In Europe *S. stricta* occurs on the salt flats of south-east England, France, Portugal and the Adriatic *S. alterniflora* has been known at Southampton since 1829, where it was probably introduced by shipping from America The genus is remarkable for the sudden appearance of a new distinct form at Southampton in 1870, *Spartina Townsendii,* H. and G Groves This tall-growing and robust form has spread widely in recent times on the soft tidal muds of both sides of the English channel (Southampton water, Portsmouth, Poole harbour, etc, and in the Vire, Seine and other French rivers). *Spartina Townsendii* is exceptional in colonizing soft mud previously bare, for the vigour of its spread, and for its power of holding silt and raising the level of the mud Since 1924 it has been introduced into Holland and planted in large numbers on the bare muds of the Scheldt, in Zeeland, and elsewhere, with a view to hastening the time when such ground could be banked (poldered) and used for agriculture

(F. W. O)

SPASM: *see* CRAMP; MUSCLE AND NERVE

SPASMODICS, THE, a name given to a group of English poets in the '40s and '50s of the 19th century. It was first applied by W. E Aytoun in *Blackwood* (May 1854) in a mock review of his own satire, *Firmilian: a Spasmodic Tragedy* (E A Poe had used the word "spasmodist" five years earlier). The writers usually classed as spasmodics are P J. Bailey (*Festus,* 1839), Ernest Jones, the Chartist song-writer, Ebenezer Jones, also a Chartist (*Songs of Sensation and Event,* 1843), Sydney Dobell (*The Roman,* 1850; *Balder,* 1854) and Alexander Smith (*A Life Drama,* 1853; *City Poems,* 1857). But it would be difficult to exclude some of Mrs Browning's early work (*Seraphim,* 1838; *Drama of Exile,* 1845), before she had assimilated her husband's influence, and Tennyson's *Maud* (1855) is in its violence, sentiment and frequent lapses of taste not far removed from the spasmodic manner. In the '40s the romantic impulse was exhausted and the Augustan notions of form discredited; but Tennyson and Browning had not risen to acknowledged ascendancy, and M. Arnold had not formulated the new canons of criticism The interim was a time of false starts, of poets whose aspirations, excited by Byron and Shelley, were unrestrained by any tradition of style or any effectual contemporary criticism.

SPEAKER, a title of the presiding officer in the legislatures of various countries. In the English parliament the lord chancellor acts as Speaker of the House of Lords, but should his office be in commission the Crown usually appoints a Speaker to supply his place, a case in point being that of Sir L. Shadwell, vice-chancellor, who in 1835 was appointed Speaker during the time the Great Seal was in commission.

The Speaker of the House of Lords need not necessarily be a member of the house; Brougham in 1830 sat on the woolsack as Speaker in his capacity of lord chancellor, being then plain Mr. Brougham, his patent of nobility not having yet been made out. The House of Lords has also deputy Speakers who are appointed by commission. The duties of the Speaker of the House of Lords are defined by a standing order as follows. "The lord chancellor, when he speaks to the house, is always to speak uncovered and is not to adjourn the house, or do anything else as mouth of the house, without the consent of the Lords first had, except the ordinary thing about bills, which are of course, wherein the Lords may likewise overrule; as for preferring one bill before another, and such-like; and in case of difference among the Lords, it is to be put to the question; and if the lord chancellor will speak to anything particularly he is to go to his own place as a peer" The Speaker of the House of Lords, as compared with the Speaker of the House of Commons, is an official without power; even his seat, the woolsack, is technically outside the house Contrary to the practice in the Commons, he acts as a strong party man, making speeches on behalf of Government measures as a peer

THE HOUSE OF COMMONS

From time immemorial the Speaker of the House of Commons has been the guardian of its powers, dignities, liberties and privileges which the house has won for itself in a period extending over seven centuries. Chosen by his fellow-members, subject to the approval of the Crown, to preside over their deliberations, the Speaker is entrusted with the duty of enforcing multifarious rules and orders, the outcome of long years of experience. These include the putting every question on bills and motions before the house. They empower the chair to accept or refuse the closure, to check irrelevance or tedious repetition, to quell disorder, to issue warrants for the issue of new writs, to reprimand, or, if may be, to commit offenders against its rules.

Often, also, it is the duty of the Speaker to decide on the spur of the moment, what is and what is not a parliamentary expression. In recent times at least one occupant of the chair had constantly by his side a list of admissible parliamentary expletives. From time to time new adjectives and nouns have to be adjudicated upon but it is within the discretion of the chair to determine how far they must be taken with the context and the circumstances of the moment, since it is possible for a word to be used in the heat of the moment in a manner calculated to give offence which, on another occasion, might pass without objection from any quarter of the house.

The most weighty decisions have from time to time to be taken at short notice by the chair, on its being suddenly confronted with an unprecedented situation. These decisions require, in addition to infinite tact, patience and courage, the prompt exercise of that peculiar authority and understanding of men which the confidence and respect of the house at large can alone confer.

The difficulties which confronted Shaw-Lefevre, who was first called to the chair in 1839, when the evolution of the non-partisan Speaker was all but complete, have increased tenfold since that date. A multiplicity of causes have fundamentally changed the temper and spirit of the House of Commons at the present day. The successive lowerings of the franchise, the formation of small subsidiary parties acting independently of the official whips, the heavy strain of practically continuous sessions, the altered mode of procedure mostly tending to enhance the power of the Government of the day at the expense of the independent member, have increased the ever-growing responsibilities of the chair. Tradition, however, binds the Commons together with amazing strength and so long as the peculiar and essential functions of the chair—in ruling by general consent rather than by compulsion, in upholding freedom of speech without allowing it to degenerate into licence—are maintained, it seems safe to predict that the proud heritage of seven centuries of liberty and progress will be handed on unimpaired to future generations of a free and self-governing nation.

The place of the Speaker in the scale of social precedence has been defined by order in council so recently as 1919, as ranking next after the prime minister and the lord president of the council and coming before all peers of the realm except the archbishops. Unlike the lord chancellor who, in his capacity of the Speaker of the House of Lords, is entitled to take part in debate and speak in favour of the Government of which he is a member, the Speaker of the Commons, free from all party ties during his tenure of the chair, takes no part in the discussions upon bills or motions and only gives his casting vote in the event of the numbers in a division being equal.

HISTORY

The Middle Ages.—The ancient office of Speaker, the *Parlour* or Moderator of the House, does not emerge from the twilight which shrouds its origin until the last of Edward III.'s many parliaments. Yet it would seem that some corresponding official charged with the duty of reporting to the Crown the decisions of the Commons existed at least half a century earlier though, as yet, he is nowhere definitely described as their presiding officer. In 1327 the Commons had demanded, no doubt by some accredited agent of their own choice, that their petitions should thenceforth be enrolled as statutes and in 1329, growing bolder still, they refused to assent to a levy equivalent to that already voted by the Lords until the parliament should be dissolved and another one summoned (*Rot. Parl.*, vol. i., p. 104), a request to which the king was graciously pleased to accede. The intermediary on this occasion between the elected representative of the people and the Crown would appear to have been Monsieur William Trussell who in 1346 found honourable burial in Westminster Abbey. In 1340 he announced a naval victory to the Commons and undertook on their behalf to raise wools for the king's aid, whilst in 1343 the Rolls relate that the knights of the shire and the borough members replied in the White hall of the palace of Westminster, by the mark of the same presiding officer, to a message from the pope.

In 1363, though the Commons then had their own clerk—one Robert de Melton, whose annual salary was 100s., it has not been possible to ascertain who filled the chair thus early. The name of a Speaker is first recorded in the Rolls of Parliament for Jan. 1377. Sir Thomas Hungerford, knight of the shire for Wilts. who died Dec. 3, 1397, is then described as the "Chivaler qui avoit les paroles pour les Communes d'Engleterre en cest Parlement." (*Rot. Parl.*, vol. ii., p. 374.) In a house mainly controlled by John of Gaunt, for the king was now in his dotage and nearing his end, the Speaker composed a daring speech to the throne at the close of the session, calling attention to various grievances and alleged infringements of the liberties of the king's subjects, both male and female. He also delivered seven "Billes to the clerk of the Parliaments, to which, however, no reply was vouchsafed. 'A cause q le dit Parlement s'estoit de partir et finir a mesme le jour devant q rien y fust plus fait en ycelles.' "

A surprisingly large number of Speakers died a violent death. Sir John Bussey, the last of the Plantagenet Speakers, was beheaded in 1399 after the surrender of Bristol to Henry, duke of Lancaster, afterwards Henry IV. William Tresham was murdered in 1450, Thomas Thorpe beheaded in 1461, Sir John Wenlock killed at the battle of Tewkesbury in 1471; Sir Thomas Tresham, son of William, was beheaded at the same place. William Catesby shared a like fate after the battle of Bosworth in 1485, Empson and Dudley paid the penalty of their crimes on the scaffold in 1510, but since Sir Thomas More was foully done to death on the perjured evidence of Rich in 1535, no occupant of the chair has been either killed in battle or brought to the block. Sir John Trevor was expelled from the house for taking bribes in 1695.

Tudor Period.—With the close of mediaeval monarchy and the advent of a more personal element in the relations of the throne towards parliament much of the sturdy independence which had animated the earlier occupants of the chair disappeared, at all events for a time. Patriots like de la Mare who used their position in the house to call attention to the urgent necessity of maritime defence, independent leaders like Arnold Savage and Tiptoft, who did not shrink on occasion from admonishing the sovereign on his shortcomings, compare not unfavourably with the servile tribe of Speakers who monopolized the chairs in the Tudor period.

The Dudleys and Empsons of Henry VII., the Riches and Audleys of his successor on the throne and the Snagges and Puckerings of Elizabethan memory would have been impossible under the Plantagenets. The opening of the Black or Reformation parliament in Nov. 1529, the longest known to that date, extending as it did over six and a half years, synchronized with a period of degradation of the House of Commons unparalleled before or since that time, although under Speaker Audley (whose promotion coincided with Wolsey's disgrace) only the outworks of the Church were laid siege to, after his transference to the Woolsack in 1533, when the chair was filled by Sir Humphrey Wingfield and, in the next parliament by the despicable Richard Rich, a series of confiscatory Acts designed to ensure the final breach with Rome were drawn up by the privy council, acquiesced in by a subservient House of Lords and forced through the house of Commons. Speakers Audley, Wingfield and Rich eventually benefited largely by the dissolution of the monasteries, Audley acquiring Christ Church priory in London and the abbey of Walden in Essex, Rich being rewarded with the spoils of St. Bartholomew's priory at Smithfield, whilst Wingfield obtained large grants of Church lands. To such a degree of subserviency to the Crown was the house reduced under Henry VIII. that when Wingfield was

committed to the Tower during the session of 1539–40, for advising Sir John Skelton how to evade the Statutes of Uses in his will, his imprisonment passed without remonstrance by the house at large.

Onslow.—The emoluments of the chair at the close of the 16th century were so small that the natural trend of a lawyer's ambition was towards the better paid offices of his profession, and not until the reign of Charles II, when Sir Edward Seymour, an aristocratic Tory, was called to the chair, did the house revert to the practice of choosing a country gentleman to preside over its deliberations. Thus for more than a century and a half the direct road to the chair led through Westminster hall and not through the gateway of St. James's palace, as Sir Robert Walpole told Arthur Onslow when in early life he expressed a desire to become Speaker His ambition was realized in 1728 and by common consent he is held to have been one of the greatest Speakers the house has ever known. He was the first to realize the supreme importance of the independence and impartiality of the chair, whereas most of his predecessors had been pluralists or expectant office holders. He raised the character of his position in the State by relinquishing the lucrative office of treasurer of the navy and contenting himself with the modest income derived from fees on private bills His patriotic action contrasts very favourably with that of Speaker Grenville in the next century when, on becoming prime minister of "all the talents," he obtained the sinecure office of auditor of the Exchequer, worth £4,000 a year, for 40 years

For length of service Arthur Onslow's 33 years in the chair easily holds the record, though Speaker Manners-Sutton remains to this day the only man who has been Speaker in seven successive parliaments, narrowly missing, by only ten votes, being chosen for the eighth time in 1835.

19th Century.—In modern times one of the most conspicuous successes in the chair was Speaker Shaw-Lefevre (Lord Eversley) with whose appointment in 1839 the evolution of the non-partisan Speaker was all but complete. Nature had marked him out as the fittest representative of an assembly of English gentlemen and from the first he won the approval of all parties. He could call unruly members to order with a smile which disarmed anger, yet, when compelled to exercise a sterner authority, his manner could be both resolute and unbending Lord John Russell said of him. "He was the best Speaker I ever knew. Where there was not a precedent he made one, adding so as to prevent any further discussion, according to the well known practice of the House, a formula which pleased everyone" Shaw-Lefevre died in 1888, in his 97th year, at which date Speaker Peel had been twice called to the chair, in 1884 and again in 1886, and Speaker Lowther (Lord Ullswater) was already a member of the house When Denison was chosen to succeed him and asked Lord Eversley if there was anyone he could call to his assistance in a difficulty he was told "You must learn to rely entirely upon yourself." During the last year of his tenure of the chair Denison enjoyed the invaluable assistance of Sir Thomas Erskine May (Lord Farnborough), who became clerk of the house in 1871, but in his interesting diary privately printed in 1900, Denison has left it on record that he spent the first few years of his Speakership "like a captain of a steamer on the Thames, standing on the paddle box, ever on the look-out for shocks and collisions The house is always kind and indulgent, but it expects its Speakers to be right If he should be found often tripping, his authority would soon be at an end"

A list of Speakers, most of whom are separately noticed, from 1600 is appended. The date of election is given in brackets:—

Sir J. Croke (1601).
Sir E. Phelips (1604).
Sir R. Crewe (1614).
Sir T. Richardson (1621).
*[1]Sir T. Crewe (1624).
Sir H. Finch (1626).
Sir J. Finch (1628).
Sir J. Glanville (1640).
Sir T. Hanmer (1714).
*Sir S. Compton (1715). *(Earl of Wilmington)*
*[2]A. Onslow (1728).
*Sir J Cust (1761).
*Sir Fletcher Norton (1770) *(Lord Grantley)*.
*C. W. Cornwall (1780).

*Speaker in more than one parliament.
[1]Brother of Sir R. Crewe.
[2]Nephew of Sir R. Onslow, Speaker in 1708, and great-great-great-grandson of R. Onslow, Speaker in the second parliament of Elizabeth.

*[1]W. Lenthall (1640).
H. Pelham (1647).
Rev. F. Rous (1653).
Sir T. Widdrington (1656).
B. Whitelocke (1656. temp. *locum tenens*).
C Chute (1659).
Sir L. Long (1659).
T Bampfylde (1659).
W. Say (1660).
Sir H. Grimston (1660).
Sir E. Turnour (1661).
Sir J. Charlton (1673).
*Sir E Seymour (1673).
Sir R Sawyer (1678).
Sir W. Gregory (1679).
*Sir W. Williams (1680).
[2]Sir J. Trevor (1685).
H. Powle (1689).
P. Foley (1695).
Sir T Littleton, Bt. (1698).
*R. Harley (1701). *(Earl of Oxford)*
J. Smith (1705)
Sir R. Onslow, Bt (1708)
W. Bromley (1710).
W. W. Grenville (1789). *(Lord Grenville)*.
*[3]H. Addington (1789). *(Viscount Sidmouth)*.
Sir J Mitford (1801) *(Lord Redesdale)*.
*C Abbott (1802). *(Lord Colchester)*.
*[4]H C M Sutton (1817). *(Viscount Canterbury)*
*J Abercromby (1835) *(Lord Dunfermline)*
*C. Shaw Lefevre (1841). *(Viscount Eversley)*
*J. E. Denison (1857). *(Viscount Ossington)*.
*H B Brand (1872) *(Viscount Hampden)*
*A. W. Peel (1884) *(Viscount Peel)*.
*W C. Gully (1895) *(Viscount Selby)*
*J W Lowther (1905) *(Viscount Ullswater)*
*J H Whitley (1921)
E A Fitzroy (1928)[1]

*Speaker in more than one parliament
[1]Speaker of the Long Parliament
[2]Convicted of bribery and expelled. 1695.
[3]Afterwards Prime Minister. Was first Speaker of the Commons of the United Kingdom
[4]Speaker in seven parliaments.

The title of Speaker is also applied to the presiding officer of the various legislative assemblies in the British colonies, that of president being applied to the presiding officer of the upper houses—legislative councils, as they are usually called In Canada, however, the presiding officer both of the Senate and the House of Commons is termed Speaker In the United States the Speaker of the House of Representatives is one of the most important officials in the government For a full description of his powers *see* UNITED STATES *Constitution and Government*

BIBLIOGRAPHY.—Stubbs, *Constitutional History*, J A Manning, *Lives of the Speakers* (1850); E. Lummis, *The Speaker's Chair* (1900) (A. I. D)

SPEARMINT (*Mentha viridis*), a species of mint (*q v*) used for culinary and other purposes, distinguished by its smooth sessile leaves and tapering flower-spikes. The flowers are pale blue, and appear from July to September Spearmint has been introduced into the United States where it has become widely naturalized in moist waste grounds The volatile oil from spearmint is also used as a medicine *See* MINT; PEPPERMINT.

SPECIE POINT: *see* GOLD POINT.

SPECIES. The nature of species is a question of considerable importance in general biology and the species is regularly employed as a classificatory unit in systematic botany, zoology and mineralogy The word *species* has, however, an important history outside those sciences It was the Latin equivalent of the Greek εἶδος ἰδέα. This meant primarily shape or visible form, but was extended to cover the sensible character of things generally, and also the intelligible For the former use compare the term "sensible species" or characters in things perceived, because reproduced in the organs of sense. To the supposition that we see these reproductions is partly due the doctrine that the mind perceives directly only its own ideas. So Locke says (*Essay Concerning Human Understanding*, Introduction, § 8) that he uses the word idea to express whatever is meant by *phantasm, notion, "species."* As intelligible character, εἶδος or *species* was the common essence of individuals or instances, as we say, of the same kind. As such it was an object of thought, not of sense; universal, not individual: and, unlike its instances, exempt from generation and decay. Its relation to its instances (which may be compared to that of a law to the events exemplifying it) was a subject of dispute both in Greek and scholastic philosophy. There were also disputes about the relation of species to their common genus, of which they are determinations (so that Aristotle compared the relation of genus to species with that of matter to form), and to the properties connected and accidents conjoined with their specific nature in instances of a species Boetius' Latin translation

of the *Isagoge* (Introduction) written by Porphyry (born A.D. 232) to the *Categories* of (or ascribed to) Aristotle made these questions familiar long before the revival of Aristotelian learning in the West. In particular it was disputed whether species and genera were anything real independently of our minds, or only common names, or else notions of ours, the products of our classifying activity. A settlement of these questions is not necessary to the work of the systematic biologist; but they must be faced if we are really to understand what we mean by the evolution of species; for this evolution is a process of which no persisting material thing is the subject. (H. W. B. J.)

BIOLOGICAL SPECIES

In systematic zoology and botany the term at present denotes a group of individual animals or plants which is allotted a more or less definite place in the hierarchy of classification between the genus and the variety. A species may be divisible into several varieties or sub-species and a genus may contain one or more species. As the differences between varieties are often very difficult to recognize, it is the species that to the untrained observer usually seem to represent the simplest distinct assemblages or "kinds" in the animal and plant kingdoms. Thus the missel-thrush (*Turdus viscivorus*) can be recognized as distinct from the song thrush (*T. philomelus*) with greater or less ease, but their varieties are only regularly perceptible after intensive study.

Aristotle was the first to use the term "species" in natural history and it was employed by him in the logical sense outlined above, *i.e.*, as denoting a lower division of a higher class. Groups which rank as species in certain of his larger classes are themselves subdivided into species. Thus the crabs and squills are treated as species of Crustacea and the crabs are again subdivided into species. For many centuries after Aristotle the species-concept was employed in this manner. It is true that differences between closely related organisms, such as the wild and cultivated races of plants, were appreciated by the Greek naturalists and herbalists (*e.g.*, Hippo of Rhegium, 423 B.C.), but the early naturalists were not concerned with the production of a "natural" scheme of classification, and names were bestowed upon animals and plants without any reference to such a system. But it would not be true to say that the early naturalists and pharmacologists had no knowledge of the diversity of nature. Many of them were fully acquainted with their local floras; students such as Dioscorides were able to enumerate as many as 1,000 kinds of plants. Our modern classification is based on the principle of relationship and it was probably not until botanists began to cultivate plants experimentally and to collate their results with herbarium collections that the importance of relationship was grasped. Progress upon these lines was made by the Swiss botanist, Caspar Bauhin (1550–1624). Towards the end of the 17th century Martin Lister, an English naturalist, who founded the special study of conchology, employed the species concept in his *Historiae Conchyliorum* (1685) very much as it is used now. Certain groups recognizable as genera in modern classification were subdivided by him into subordinate groups (not actually called species) which were according to the custom of the time designated by their distinctive characters. It is, however, to John Ray, another English naturalist, and a contemporary of Lister, that we owe the first serious discussion as to the status and nature of species and the use of the criterion of mutual fertility as a test of specific identity. The position of the species as the lowest member of a classificatory system was exactly defined by C. N. Lang (1670–1740). At this period there seems to have been no attempt to delimit species one from another with any strictness of definition. A notable feature was a growing interest in their origin, and, as Bateson (1913) has pointed out, there was a distinct tendency to believe that they could arise spontaneously. This belief was, however, checked by the influence of C. Linné (*see* LINNAEUS). The celebrated Swedish naturalist in his *Philosophia Botanica* (1751, §157) made use of the following definition: *species tot numeramus quot diversae formae in principio sunt creatae,* which may be freely rendered "our classification contains just so many species as there were different forms created in the beginning." This famous aphorism is accompanied in the text by a quotation from an earlier work, the *Classes Plantarum* which leaves no ambiguity as to the meaning of *in principio—species tot sunt quot diversas formas ab initio produxit infinitum Ens* ("there are as many species as there were different forms produced in the beginning by the Infinite Being"). Linné thus regarded species as archetypal—as definite entities immutable and fixed in the mould of the original creation. The quotation proceeds: *quae formae secundum generationis inditas leges produxere plures at sibi semper similes* ("these forms according to the laws of reproduction have produced more [sc. individuals] always like themselves"). It must be observed that the aphorism and its accompanying quotation, when read in conjunction with the definition of variety, (1) define the origin of species and (2) propose as criteria of specific status the test of breeding true to type and the structural uniformity of the constituent individuals.

For nearly a century after Linné's death the doctrine of the fixity of species was upheld by the majority of biologists. The effect of Darwin's exposition of the causes of evolution and the evidence he produced in favour of natural selection very naturally led to the rejection of the Linnaean doctrine. The implications of Darwin's theory plainly pointed to the conclusion that varieties are incipient species and that species are progressively developed by the selection and accumulation of individual variations from a parent stock, aided in some measure by isolation. The line between variety and species is often imperceptible and, in Darwin's words, the term species "is arbitrarily given" and "does not essentially differ [in meaning] from the term variety." He held that the only criterion by which we can decide whether a doubtful form is to be ranked as a species or as a variety is "the opinion of naturalists having sound judgment and wide experience." It had previously been urged that the sterility of hybrids resulting from certain crosses afforded a good general criterion of specific distinctness. Darwin showed that this criterion could not be accepted, as the degree of sterility of various species when crossed is so different "that for all practical purposes it is most difficult to say when perfect fertility ends and sterility begins." It should be clearly understood that the acceptance of this opinion concerning species does not mean that the naturalist is unable to recognize such distinct and sharply defined groups as may actually occur in nature. What was abandoned was the belief in the special creation of species and the less definitely expressed but implicit conception of a criterion by which species could be regularly recognized as distinct, *e.g.*, from varieties.

Since the publication of the *Origin of Species* up to the present time many zoologists and botanists have resolutely followed Darwin in regarding the criterion of specific status as an arbitrary matter having a purely systematic value and in believing that species cannot be regularly discriminated from other categories as a distinct and standardized evolutionary grade. On the other hand there have been many students who, influenced by advances in our knowledge of the laws of heredity, have been less disposed to deny to the species a special and peculiar status. Alexis Jordan and H. de Vries showed that some of the Linnaean species were not homogeneous in hereditary constitution but were composed of a number of subdivisions or "elementary species." According to de Vries these arise not by slow progressive selection, but by sudden discontinuous change (mutation). The origin of new forms, whether they be "species," "subspecies" or "races" is discussed in the article EVOLUTION. It may be stated, however, that, although mutation in de Vries' original sense has not been shown to be of general occurrence, new forms have arisen as the result of crossing. These are recorded among plants and it may be noted that they sometimes fulfil the ordinary criterion of species. A more exact knowledge of the mechanism and laws of heredity was developed in the years following the republication of G. Mendel's celebrated investigations in 1900 (*see* HEREDITY, MENDELISM). Experimental pedigree culture and work such as that of Johannsen on Pure Lines (*q.v.*) yielded evidence of the same type of hereditarily constant strains as were demonstrated by Jordan and de Vries. The species thus recovered some of its lost prestige, at least in so far as the existence of ultimate units seemed to be

established. In 1913 Bateson could speak of "the universal presence of specificity" among animals and plants. Most biologists at the present time, however, are unwilling to admit that species can be discriminated from varieties by a universal criterion.

Some points concerning variation and other matters may make the reason for this conclusion clearer and should at the same time indicate the difficulty encountered in trying to fit into rigid categories the variation that is found in nature. (1) A distinction must be drawn between the species described in systematic zoology and botany, or known to the casual observer, and the "natural population." The first is represented by the usually limited number of individuals accessible to the naturalist or encountered by the observer and is only a sample of the natural population found in nature. Very often the species of the systematist are represented by a few specimens only and it is rarely that the distribution and variation of species in nature are known with any exactness. (2) When such natural population are studied in detail it is often found that they are far from homogeneous. Not only do the individual organisms referred to a species differ somewhat among themselves in single characters, but also the combinations of characters which they exhibit are often very diverse. A form designated as a species may be split up into local races which differ in the extent to which they are differentiated one from another. (3) It is sometimes possible to recognize distinct and discontinuous groups; but forms diagnosed as species are often found to grade by a series of intermediate forms into other groups and species thus connected by intermediates and having many characters in common are only recognizable by the fact that certain combinations of characters are more frequently found than others. The difficulty of defining species with exactness has been shown with particular clearness in the study of certain fossil animals The intensive study of series of such forms obtained from strata succeeding each other in regular sequence usually shows a gradual change of one form into another and sometimes the "lineages" or successive phases of individual characters are so inextricably confused as to make it impossible to recognize species in the ordinary systematic sense. (4) Intermediate forms may be of two kinds. "mid-intermediates," *i e.*, forms in which all the characters represent a blend of two more extreme types (as grey is intermediate between black and white), and forms which represent various combinations of some of the characters found in two divergent stocks. The former may owe their intermediate appearance to the local environment and both kinds of intermediacy may be due to the effects of hybrid crossing (5) The recognition of species by a morphological criterion is embarrassed by the occurrence of sexual dimorphism, *i e*, the occurrence of strongly marked differences in structure or colour between the males and females of a single species. (6) The criterion of specific distinctness usually adopted is that of structural difference Evolutionary divergence, however, is manifest in many other attributes of animals and plants—in the products of their metabolism, their reactions, habits, distribution, etc. It is found that the various modes of distinctness—structural, physiological, habitudinal, etc.—are not very closely correlated. For example, forms which are morphologically distinct may be mutually fertile or have identical physiological properties or activities. Although it is customary to regard structure as the surest clue to relationship it is nevertheless to be borne in mind that structural differences do not constitute the only type of divergence and that, while our classification aims at expressing genetic relationship, it does not necessarily express the functional diversity of animal and plant life It is perhaps desirable to emphasize the purely arbitrary nature of the criterion of specific status. Although at any one time it is possible to recognize tolerably distinct assemblages of individuals on which it is convenient to confer specific rank, nevertheless the limits of such "species" are, when considered in the light of evolutionary history, incapable of exact definition.

In systematic zoology and botany a species is designated by two names, the generic name, indicated by an initial capital letter, and the specific, which is always now printed without a capital in zoology, though in botany the initial letter is a capital, if derived from a proper name. Both names are printed in italics and may be followed by the name of the author who published the first description of the species Thus *Corvus corax* Linné (or Linn) is the specific designation of the raven Owing to complications introduced by certain inevitable errors the nomenclature of species and genera is subject to a code of international rules.

The first described specimen of a species is known as the "type" of the species ("co-type" and "paratype" being used for various grades of "types"), a term which must not be confused with "typical," *i e.* average.

In mineralogy the classificatory system is not based upon descent and relationship. Certain fundamental kinds of minerals known as "species" are recognized and defined according to their chemical composition and crystalline form. The larger groups are quite arbitrary and depend upon the purpose for which the classification is to be used. Some of the species of minerals are clearly defined. (*See* MINERALOGY.)

SPECIFIC GRAVITY is the ratio between the density (mass per unit volume) of a body and the density of some substance assumed as a standard For liquids and solids the standard is distilled water at 4 deg C. In the centimetre-gram-second system of units the numerical values for the density and the specific gravity of any substance are the same. In the English system the density of water is 62·4 pounds per cubic foot, while its specific gravity is still unity. (*See* PHYSICS, ARTICLES ON)

SPECIFIC PERFORMANCE, an equitable doctrine under which a court of equity, in certain exceptional cases where the normal legal remedy, *i e*, damages, would not be a sufficient compensation, orders by a defaulting party a specific or actual performance of the thing which he had contracted to do. The court as a general rule will refuse this relief where it would be unable to superintend or enforce the execution of its judgment. Specific performance is usually confined to executory agreements, *i e*, a conveyance or a lease of land; it is not usually enforced in the cases of personal acts or in those of contracts for personal service. The doctrine of specific performance in the United States follows very largely that of England

See *Ency Eng. Law,* tit. "Specific Performance"; J. Story, *Equity Jurisprudence* (1836); Sir E. Fry, *Treatise on Specific Performance of Contracts* (6th ed., 1921).

SPECTACLES, the name given to lenses of any required form which are supported in front of the eyes to assist vision. They may be required to correct errors of refraction, or to correct imbalance of the ocular muscles, or to cut off injurious or unpleasant light or glare. The lenses for the first two purposes are usually made of crown glass, but in the early days, when it was not easy to obtain glass of good quality, free from striae (*i e.*, streaks of glass of a different refractive index, due to imperfect mixing of the constituents), they were also made of quartz, or rock crystal as it was called Some years ago quartz lenses were revived by the opticians, and sold at fancy prices, on the erroneous plea that they were cooler to the eyes.

Professor M. von Rohr has discussed the history of Spectacles in several papers (*See* Thomas Young Oration, Trans. Optical Soc. 1923–4 No. 2 and also in 1926–7 No. 3.) Briefly, it appears that Roger Bacon explained how to magnify writing by placing a segment of a sphere of glass on the book with its plane side down in his Opus Majus 1266. A portrait of Cardinal Ugone in a fresco in a church at Treviso painted in 1352, shows two mounted lenses with their handles riveted together and fixed in front of his eyes, so evidently a form of spectacles was known by this time. Up to the invention of printing in the middle of the 15th century, very few other than the monks could read, but the advent of the printed book greatly stimulated the demand for spectacles, and the trade in them grew rapidly during the 16th century, especially in North Italy and South Germany where

there were glass workers, and by about 1600 opticians were to be found in most of the towns of any size on the continent. The early mounts were made of horn and leather, and by about this time metal began to be used. The nomenclature of the lenses varied; in Venice it is possible that the numbering represented the power of the lens, with a unit of about 0·6 diopters. Elsewhere they were either numbered to indicate the age for which they were supposed to be used, or according to the radius of the tool in which they were ground. In Germany spectacles were made for the very low price of 2½ to 4 farthings, and were extensively exported. We have no information of the beginning of the optical trade in England, but in 1629 a charter was granted by Charles I. to the Spectacle Makers' Guild. The invention of the method of grinding a number of lenses together on one large block, which Mr. Court has shown was made by Marshall between 1690 and 1693 (Trans. Opt. Soc. 1926–7, p. 122), gave the London opticians a very great advantage over their foreign rivals, as it enabled them to produce lenses of a better quality; and during the 18th century they acquired a great reputation, and were able to charge as much as sixteen guineas for the best double-jointed standard gold spectacles (gold case included) (Trans. Opt. Soc. 1923–4, p. 64). They introduced the fashionable monocle about this time.

Bifocals, that is, lenses of which one portion has a higher power than the remainder, appear to have been first made for Benjamin Franklin about 1760.

Astigmatism, that is, a variation in the refractive power of the eye in different meridians, was first recognised by Thomas Young, who found it present in his own eyes. He found he could correct it by looking obliquely through his spectacles, so it must only have been slight. Sir George B. Airy in 1825, who had one eye so badly astigmatic as to be unusable, showed that the astigmatism could be corrected by a spherocylindrical lens, and had such a lens made for himself by Fuller, an Ipswich optician, in 1827. Cylindrical lenses, however, were seldom prescribed or supplied until towards the end of the 19th century.

In the last few years great improvements in the construction of bifocals have been made. The early bifocals were made by cutting away a portion of the weaker lens, which corrected the wearer's error for distant vision, and replacing it by a part of a stronger lens, adapted for his reading distance. The two partial lenses were mounted together in the frame, so that when he looked up he looked through the weaker lens, and when he looked down, he saw through the stronger one. The first improvement was to cement an extra lens over the lower part of the weak lens, so as to increase its power by the required amount over this area.

In another form of bifocal lens, the surface of a single lens is ground to two different curvatures, by using a rotating hollow brass tube and emery to grind with, and an ebonite tube with rouge to polish with. If well done this lens is very satisfactory.

In another form, a hollow is first ground and polished in the crown lens; then a flint lens is ground and polished to the same curve. The flint is laid in the hollow in the crown lens, great care being taken to avoid including dust or air, and the two are fused together in an electric furnace. The outer surface is now ground all over to the same curvature, and the included flint lens is therefore almost invisible, but as it has a higher refractive index than the crown, this part of the lens will have a higher power, determined by the curvature of the dividing surface between the crown and the flint. This combination, being a convex flint and a concave crown, is non-achromatic. So lastly instead of a flint glass, a boro-silicate crown has been substituted, and as this glass has a lower dispersive power than the crown, although it has a higher refractive index, the combination is partly achromatized.

The refractive errors of the eyes to be corrected by spectacles are of three kinds: (i.) those due to malformation of the eye, (ii.) those due to old age, (iii.) those due to want of proper co-ordination of the muscles of the eye.

(i.) The first of these may be again divided into two main types: (a) The curvature of the cornea or of the lens may be too great or too small in relation to the distance of the retina from them. This error can be corrected by the use of a concave or a convex spherical lens, respectively.

(b) The cornea, or sometimes the lens, may not be symmetrical about its axis, being more curved in one meridian than in the one at right angles. This makes it impossible for the eye to form a point image of a bright point, the eye is therefore said to be "astigmatic." As already mentioned, this defect can be corrected by adding a cylindrical lens to increase the power of the weaker meridian, or to reduce that of the stronger, as may be more convenient. If the error was a large one, the eye will not have attempted to correct it; but if it was small the eye will usually have tried to overcome it, and this will generally have caused more or less severe headaches. The prescription of the requisite glasses will remove these headaches.

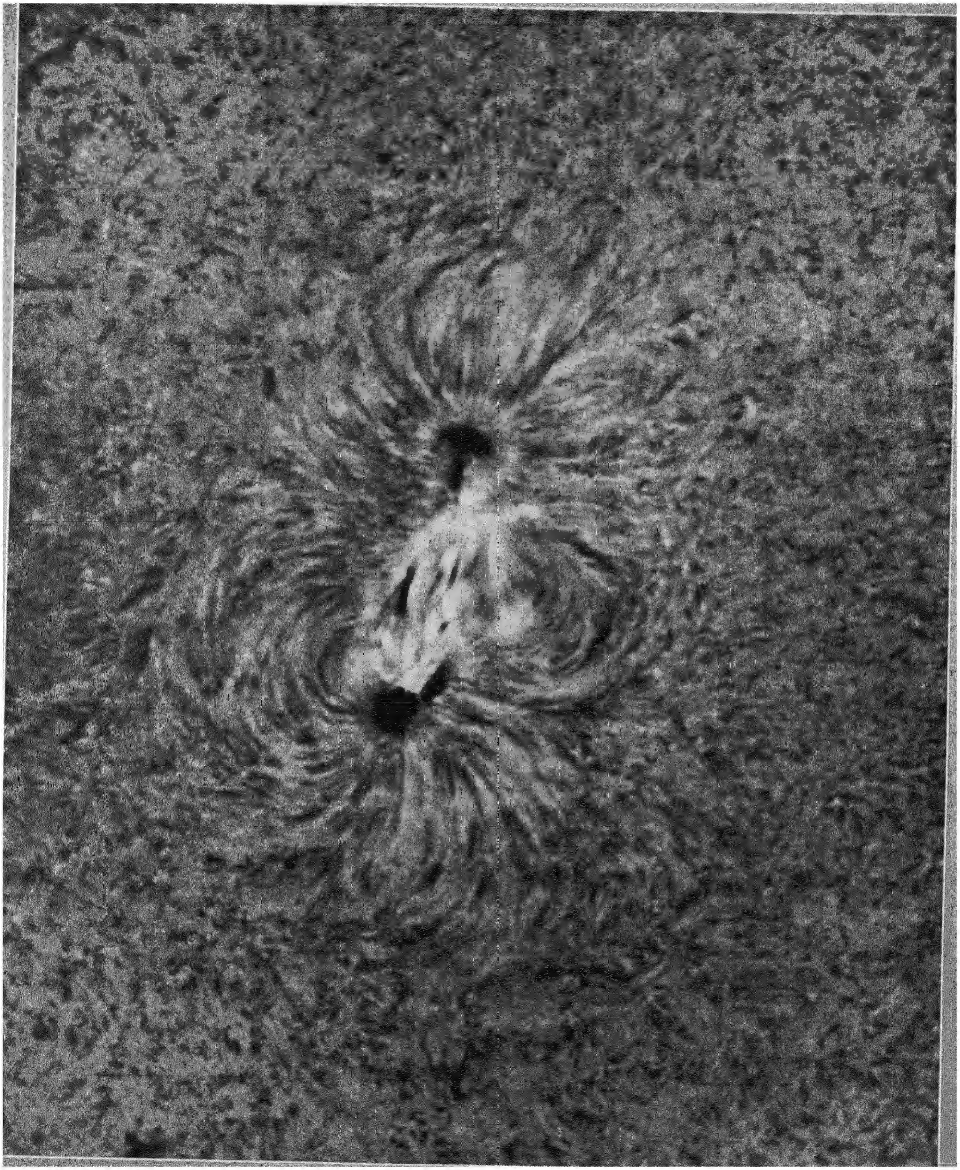
In a number of cases the malformation of the one eye is different from that of the other. A child that has one good and one bad eye, often learns to squint in order to throw the image in the bad eye out of the field. Correcting the bad eye in such a case at an early date will prevent the development of the squint. In other cases both eyes may need correction, and it is usually possible to correct both eyes fully, if the case is taken early enough.

(ii.) The effect of age is gradually to lessen the ability of the lens of the eye to alter its power, and to see clearly objects at different distances. This loss of power continues progressively through life. In the case of a person with normal sight, at about the age of fifty he begins to find it impossible to focus anything nearer than about 25 in., and therefore reading begins to be difficult. A long-sighted person will find difficulty in reading at an earlier age. As a man gets older the addition required for reading will gradually become greater, and ultimately at about the age of 70 all power of altering the focus of the eye is lost. A short-sighted person may never require glasses for reading.

(iii.) If some of the eye muscles are unequal so that the axes are normally not parallel to one another, the ganglia which co-ordinate the movements of the eyes, will have a strain thrown upon them, which may often cause trouble. This is especially the case if the axis of one eye points higher up than the other, as we have not learnt to move the eyes up and down independently. In this case severe headache may result which a prism, or a decentration of the lens, will relieve.

Lastly, spectacles may be required to cut off harmful rays of light. In the high Alps and the tropics, there is an excess of ultra-violet light, which has a harmful effect on the retina, and may even cause blindness; certain special glasses are on the market which cut off these rays. Also in some occupations the workers are exposed to similar rays, as for instance in acetylene- or arc-welding, and must protect their eyes either by wearing coloured glass goggles or by holding a screen containing coloured glass before their face. These goggles are generally glazed with ordinary blue or green glass, or sometimes with a coloured celluloid film mounted between two plain glasses. Glass blowers and metal founders are exposed to great heat radiation, this is largely cut off by any glass, but to give a pleasanter light, a blue or green tinted glass is sometimes used. (R. S. Cl.)

SPECTROHELIOGRAPH, an instrument for photographing the sun with monochromatic light. In its simplest form it consists of a direct-vision spectroscope, having an adjustable slit (called "camera slit" or "second slit"), instead of an eyepiece, in the focal plane of the observing telescope. This slit is set in a position such that it transmits a single line of the spectrum; *e.g.*, the K line of calcium. A fixed image of the sun is formed on the collimator slit of this spectroscope, and a photographic plate, with its plane parallel to the plane of the solar image, is mounted almost in contact with the camera slit. The spectroscope is then moved parallel to itself, admitting to the collimator slit light from all parts of the sun's disk. Thus a monochromatic image of the sun, formed of a great number of successive images of the spectral line employed, will be built up on the plate. As the only light permitted to reach the plate is that of the calcium line, the resulting image will represent the distribution of calcium vapour in the sun's atmosphere. The calcium clouds, or flocculi, thus recorded are invisible to the eye, and are not shown on direct solar photo-



BY COURTESY OF PROFESSOR G. E. HALE, MOUNT WILSON OBSERVATORY

HYDROGEN WHIRLS IN THE SUN

These hydrogen whirls surrounding a large bipolar sun spot were photographed at the Mount Wilson Observatory of the Carnegie Institution of Washington, with the 13-ft. spectroheliograph, Aug. 30, 1924. Photographs of the hydrogen layers of the sun's atmosphere show that sun spots are vortical in nature and that their movement may be clockwise or anti-clockwise

graphs taken in the ordinary way. These, on account of the brilliant reversals of the H and K lines to which they give rise, and the protection to the plate afforded by the diffuse dark bands in which these bright lines occur, are easily photographed with a spectroheliograph of low dispersion. In the case of narrower lines, however, higher dispersion is required to prevent the light of the continuous spectrum on either side of the dark line from blotting out the monochromatic image.

A five foot spectroheliograph which gives excellent results with the lines of calcium, hydrogen and iron has been used since 1905 in conjunction with the Snow (horizontal) and 60ft. tower telescopes of the Mt. Wilson Solar observatory. It was constructed in the observatory instrument shop in Pasadena. The instrument consists of a heavy cast-iron platform mounted on four steel balls, which run in V guides of hardened steel. Most of the weight of the instrument is floated on mercury contained in three troughs which form part of the cast-iron base. The platform carries the two slits, the collimator and camera objectives and the prism-train. An image of the sun, about 6·7in. in diameter, is formed by the telescope on the collimator slit. The collimator slit is long enough (8½in.) to extend entirely across the solar image and across such prominences of ordinary height as may happen to lie at the extremities of a vertical diameter After passing through the slit the diverging rays fall upon the 8in collimator objective which is constructed in the manner of a portrait lens in order to give a sharp field of sufficient diameter to include the entire solar image. The rays, rendered parallel by the collimator objective, meet a plane mirror made of silvered glass, which reflects them to the two prisms These are of dense flint-glass (Schott 0·102), and each has a refracting angle of 63° 29′. Their width and height are sufficient to transmit (at the position of minimum deviation) the entire beam received from the collimator. A grating, ruled on speculum metal with about 15,000 lines per inch, is substituted for the mirror when higher dispersion is required. After being deviated 180° from the original direction, the dispersed rays fall on the camera objective, which is exactly similar to the collimator objective. This forms an image of the solar spectrum in its focal plane on the camera slit Beyond the camera slit, and almost in contact with it, the photographic plate-carrier is mounted on a fixed support. In order to bring a spectral line upon the camera slit, the slit is widely opened and the plane mirror is rotated until it is possible to see the line. A cross-hair, in the focal plane of an eyepiece, is then moved horizontally until it coincides with the line in question. The slit is narrowed down to the desired width, and moved as a whole by a micrometer screw until it coincides with the cross-hair. The eyepiece is removed and the photographic plate placed in position An electric motor, belted to a screw connected with the spectroheliograph, is then started. (Two alternative screws, of different pitch, are provided to give different speeds.) The screw moves the spectroheliograph at a uniform rate across the fixed solar image. Thus a monochromatic image of the sun is built up on the fixed photographic plate.

The spectroheliograph, originally designed for photographing only the solar prominences, disclosed, in its first application by Hale at the Kenwood observatory (Chicago, 1891, 1892), a new and unexplored region of the sun's atmosphere. Photographs of the solar disk, taken with the H or K line, showed extensive luminous clouds (flocculi) of calcium vapour, vastly greater in area than the sunspots. About this time Deslandres introduced at the Paris observatory, the velocity spectrograph, which permits the motion in the line of sight of the calcium vapour at various levels to be measured on photographs of the H or K line in successive sections of the sun. By setting the camera slit of a spectroheliograph so as to admit to the photographic plate the light of the denser calcium vapour, which lies at low levels, or that of the rarer vapour at high levels, the forms of the flocculi corresponding to various superposed regions of the atmosphere can be recorded. The lower and denser vapour appears as bright clouds, but the cooler vapour, at higher levels, absorbs the light from below and thus gives rise to dark clouds

The first photographs of the sun in hydrogen light were made with the spectroheliograph at the Yerkes observatory in 1903. These reveal dark hydrogen flocculi, which, like the dark calcium flocculi, lie at a level above that of the bright calcium flocculi They also show less extensive bright flocculi, usually in the immediate neighbourhood of sunspots, and frequently eruptive in character. These rise from a low level, and sometimes reach considerable elevations in the form of eruptive prominences.

In such an exploration of the sun's atmosphere it might be anticipated that definite currents, or some evidences of atmospheric circulation analogous to those familiar in terrestrial meteorology, would be discovered. In the early work neither the forms nor the motions of the calcium flocculi revealed the existence of such currents, but in the higher region shown by the hydrogen photographs the distribution of the dark flocculi suggested the operation of definite forces, though their full effect was not recognized until the spring of 1908 At that time monochromatic photographs of the sun were first made by Hale and Ellerman on Mt Wilson with the red ($H\alpha$) line of hydrogen, previous hydrogen photographs having been taken with $H\beta$, $H\gamma$ or $H\delta$ in the blue or violet. On account of the relatively great strength of $H\alpha$ at a considerable distance from the photosphere, the new photographs recorded flocculi at high levels previously unexplored. The forms and motions of these flocculi show that great vortices exist in the solar atmosphere above sunspots, which resemble terrestrial cyclones or tornadoes About 75% of these high-level vortices indicate clockwise rotation in the southern hemisphere and counter-clockwise rotation in the northern, as in the case of terrestrial cyclones. The detection of these vortices led, in 1908, to the discovery of magnetic fields in sunspots, apparently due to electric convection in the primary vortices at lower levels which are the cause of the spots themselves. The long dark flocculi also shown on hydrogen spectroheliograms, identified as prominences projected against the surface of the sun, were subsequently called "filaments" by Deslandres, who has studied them extensively at Meudon With a spectroheliograph of high dispersion the centre of the hydrogen line $H\alpha$ shows the "alignments" discovered by Deslandres, which constitute a network of wide mesh associated with the filaments.

Spectrohelioscope.—The spectrohelioscope renders visible to the eye many of the phenomena of the solar atmosphere photographed with the spectroheliograph and also permits their velocities in the line of sight to be measured It thus combines some of the functions of the spectroheliograph and the velocity spectrograph Its principle was suggested by Young in 1870, and tried provisionally by him for the observation of prominences at the sun's limb. He discarded it, however, when the use of a wide slit was proposed for this purpose by Zollner and Huggins. Hale, who revived and developed the method (1924), succeeded with its aid in observing the bright and dark hydrogen flocculi on the sun's disk, and in analyzing and measuring the motions of the gas in eruptions and vortices

Imagine a narrow slit, rapidly oscillating, between the eye and a telescopic image of the sun. Through persistence of vision, the image can be seen in white light. Introduce a spectroscope, which excludes from the slit before the eye all light except that of the red hydrogen line. We then have a spectrohelioscope For satisfactory observations of the hydrogen atmosphere against the disk, fairly high dispersion is necessary Hale uses a spectroscope of 13ft. focal length, having a plane grating ruled with about 15,000 lines to the inch, giving a first order spectrum which is very bright in the red. He has employed various means of moving the slits, one of which is a spinning disk pierced with 50 radial slits 0·004in. wide. A 2in solar image is formed on one side of the disk and the observer sees the hydrogen image of a portion of the sun through a low-power eyepiece focussed on the diametrically opposite slits. J A. Anderson and Sinclair Smith have suggested devices for producing an exactly similar monochromatic image with a spectroscope having fixed slits. These consist of a rotating prism of square section (Anderson) or an oscillating plane mirror (Smith) which cause a portion of the solar image to move rapidly across the fixed first slit of the spectroscope The second slit is then viewed through another prism or mirror, mov-

ing at precisely the same rate and giving a fixed monochromatic image in the eyepiece.

The hydrogen lines on the sun's disk are frequently distorted by the rapid motion of the gas toward or from the observer. For example, a mass of hydrogen descending into a vortex above a sunspot is indicated by a local displacement of the lines, which frequently indicate a velocity of 60km. sec. In such a case the distorted portion of the line would fall outside the narrow slit of the spectroheliograph, and the image of the rapidly moving gas would not be recorded. The spectrohelioscope not only brings these moving gases into view but also indicates their velocity. A "line-shifter," consisting of a plane parallel-sided glass plate mounted behind the second slit, displaces the line toward red or violet when rotated. In all regions where he suspects motion, the observer frequently shifts the line on the slit, thus "tuning-in" so as to pick up the wave-lengths as altered by the motion of the luminous gases. In this way, for example, a rapidly ascending mass of hydrogen, near the middle of the sun (revealed by a line outside the Hα line on its violet side), may be watched as it shoots upward, curves over in a long arch nearly parallel for some distance with the surface (its line shown near the centre of the Hα line), and descends in a continuous arch toward the sun or is caught in a vortex and whirled downward (the line being seen outside the Hα line on its red side). A divided arc attached to the line-shifter gives the velocity of the gas.

The spectrohelioscope affords a rapid means of detecting and analysing eruptions or other important solar phenomena, as the entire limb and disk can be examined in a few minutes. Eight or more of these instruments will soon be used systematically at as many solar observatories, distributed around the world, thus permitting the sun's atmosphere to be kept under nearly constant observation. In this way it is hoped to increase our knowledge of the connection between solar eruptions and such geophysical phenomena as the aurora, the magnetic storm and certain interruptions in radio transmission, which probably depend upon the bombardment of the earth's atmosphere by electrified particles projected from the sun.

Descriptions of spectroheliographs and results by Hale, Deslandres, Evershed, Newall and others have appeared in various papers in *Astronomy* and *Astrophysics, Astrophysical Journal, Comptes rendus, Bulletin astronomique, Monthly Notices of the Royal Astronomical Society* and the publications of the Yerkes, Meudon, Kodaikanal, Cambridge and Mt. Wilson observatories. Papers on the spectrohelioscope may be found in the *Publications of the National Academy of Sciences, Nature, Astrophysical Journal* and *Publications of the Astronomical Society of the Pacific.* (G. E. H.)

SPECTROHELIOSCOPE: *see* SPECTROHELIOGRAPH.

SPECTROSCOPY (from Lat. *spectrum,* an appearance, and Gr. σκοπεῖν, to see), has for its province the investigation of spectra, which are the appearances observed when the radiations from a luminous source are separated into their constituent parts. Such separation can be effected by the use of a prism, or by a diffraction grating, and instruments which are designed for the convenient use of these appliances are called spectroscopes.

This important branch of physics came especially into prominence through the work of Kirchhoff and Bunsen in 1859, when it was primarily regarded as providing a new method of investigating the chemical nature of substances, and was called spectrum analysis. A number of elements new to chemistry were soon afterwards discovered by this method, which was found to be extremely sensitive, so that, for example, one three-millionth of a milligram of sodium could be assigned to that element with certainty. Being independent of the distance of the luminous source, the spectroscopic method was clearly applicable to the sun and other celestial bodies, and the science of Astrophysics came into existence.

It was soon realized, however, that spectrum analysis was not so simple a matter as it first appeared. The early experiments apparently suggested that each element had its characteristic and invariable spectrum, irrespective of whether it existed in the free state or in combination with other elements. But as inquiry was extended it was found that many compounds as well as elements gave their characteristic spectra, and, further, that even an element could give different spectra according to the physical conditions under which it was excited to luminosity.

The spectrum has thus become much more than a key to chemical composition; it has also become a key to the physical conditions under which the corresponding radiation is excited; and, as was clearly foreseen by some of the earlier workers, it has gone far to reveal the structure of atoms and molecules. The old name being no longer appropriate, the word "Spectroscopy" was introduced to cover the whole range of spectroscopic investigations, apparently by Sir Arthur Schuster in a lecture delivered at the Royal Institution in 1882.

1. EXPERIMENTAL BASIS

THE PRISM

The Simple Prism.—The production of a spectrum by the use of a prism depends upon the fact that rays of light of different colours, or wave-lengths, are refracted differently on entering or emerging obliquely from one medium to another of different density. Thus, in fig. 1 the ray of light AP, consisting of a mixture of red and violet light, will be split up into its two components by the prism, the red following the path PDR, while the violet, being more refracted than the red, will follow the path PEV. A composite ray of light is accordingly *dispersed,* as well as refracted, in passing through a prism. If the source of light be white, the spectrum will show a succession of colours like those of the rainbow; namely, red, orange, yellow, green, blue, indigo and violet. Beyond the visible violet there is a long range of spectrum called the ultra-violet, and there is similarly a region called the infra-red beyond the visible red end of the spectrum.

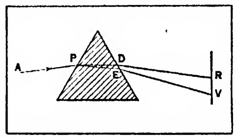


FIG. 1.—DISPERSION BY A PRISM

The essential parts of a simple prismatic spectroscope are represented diagrammatically in fig. 2. Light from the source under examination enters the instrument through a narrow slit at S, which is placed at the principal focus of a lens A. Parallel rays of light of mixed colour thus fall on the prism, and each component bundle of rays continues parallel in its passage through the prism and on emergence into the air beyond. The different bundles, however, are refracted differently, and, when they pass through the lens B are focussed at different points, so as to form a spectrum. The spectrum may then be observed with a suitable eyepiece, or it may be photographed direct. The lens B and the eyepiece are ordinarily combined in the form of a telescope, which can be rotated about the centre of the prism, so that different parts of the spectrum can be observed. When the eyepiece is replaced by a camera, the instrument is called a spectrograph.

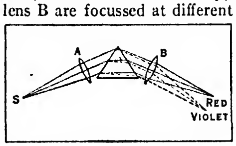

FIG. 2.—PRISMATIC SPECTROSCOPE

When produced in this way the spectrum consists of a succession of images of the slit, depending upon the nature of the source, and while the slit may be of any shape, a narrow straight slit is ordinarily used because it gives the least confusion of overlapping images. It is because a straight slit is most generally used that we speak of spectrum *lines.*

When a ray of light leaves the prism at the same angle as that at which it enters, the prism is said to be at minimum deviation for that particular colour or wave-length. This position can readily be determined by turning the prism until the line under observation advances as far as possible in the direction of the red. When a collimator is used, it is not essential for good definition that the prism should be at minimum deviation, but it is usually most convenient to place it in this position, so that a previous condition of adjustment can easily be restored.

Constant Deviation Prism.—A convenient form of prism which is optically equivalent to a 60° prism of the same kind of glass has been utilized in the Hilger wave-length spectrometer, which is illustrated in fig. 3. The prism takes the form shown in fig. 4, and though made in one piece of glass it may be considered

to be made up of two prisms with refracting angles of 30°, acting in conjunction with a totally reflecting prism ABC.

When such a prism is rotated about a vertical axis, different wave-lengths may be observed in a fixed direction at right angles

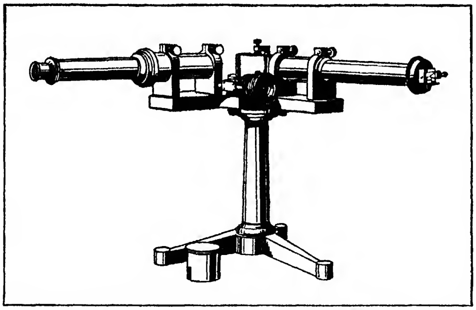

FIG 3 —HILGER WAVE LENGTH SPECTROMETER

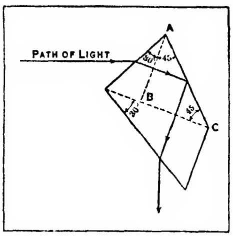
to the incident ray, and a prism of this form is consequently called a constant deviation prism Measurements are made on a large drum which forms the head of a fine tangent screw by which the prism is rotated, the divisions of the spiral scale being such as to indicate wave-lengths directly.



BY COURTESY OF HILGER

FIG 4 —CONSTANT DEVIATION PRISM

Compound Prisms.—It is often convenient to have an instrument in which the viewing telescope is in direct line with the collimator, and, of the various ways of obtaining this, the most common arrangement is that in which prisms of different kinds of glass are combined to give dispersion without deviation This is possible because in different kinds of glass dispersion and deviation are not proportional; flint glass, for example, giving a greater dispersion in proportion to deviation than crown glass Such a combination is illustrated in fig 5a, the central flint prism being supposed to have a refractive index of 1·751 and the outside crown glass prisms 1 520 These combinations may give quite a large balance of dispersion, because the flint glass prism has a much larger angle than is possible when a prism of the same kind of glass is used alone. Such prisms are used extensively in pocket spectroscopes, which dispense with an observing telescope, as well as in larger instruments. To give increased dispersion, these direct-vision prisms are often constructed with two prisms of flint and three of crown glass, cemented together, and two or more such combinations may be used in line with each other Since direct-

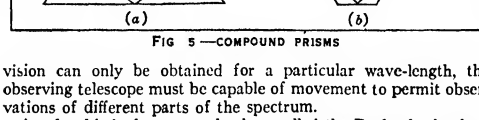


FIG 5 —COMPOUND PRISMS

vision can only be obtained for a particular wave-length, the observing telescope must be capable of movement to permit observations of different parts of the spectrum.

Another kind of compound prism, called the Rutherfurd prism, (fig 5b) is not designed to give direct vision, though somewhat similar in construction. A flint glass prism of refracting angle about 90° (which could not be used alone) is flanked by two prisms of crown glass with the angles chosen so that the light will pass conveniently through the flint prism. Sometimes, the central prism is replaced by a hollow prism filled with carbon bisulphide.

VARIETIES OF SPECTRA

Emission Spectra.—Self-luminous sources yield *emission* spectra, which are of different types according to the nature of the source. The light from an incandescent solid body such as a gas mantle, or an electric glow lamp, is spread out into a band showing all the colours of the rainbow The colours from red to violet merge into each other by insensible gradations, and the spectrum is said to be *continuous* With rare exceptions, all incandescent solids and liquids give a spectrum of this kind, and it follows that such substances cannot be distinguished from one another so long as they remain in the solid or liquid state

The effects are very different when the substances examined are in the state of luminous gas or vapour. They then emit special kinds of light by which they can be identified, whether they are subjected to experiment in our laboratories or are situated in a celestial body far away in the depths of space The spectra are *discontinuous,* consisting of a number of bright lines or bands of different colours on a dark background No two substances yield the same spectrum and it follows that the chemical nature of substances can be determined by an examination of their spectra. This is the foundation of spectrum analysis Thus, glowing hydrogen is characterized by a bright line in the red, besides others in the more refrangible parts of the spectrum, and since these are exhibited by nothing but hydrogen, they serve to indicate the presence of hydrogen wherever it occurs in the luminous state Each of the other elements also has its distinctive family of spectrum lines, some consisting of comparatively few lines, while others give hundreds or thousands of lines

The distinction between line and band spectra is of great importance A line spectrum consists of a succession of images of the slit of varying intensity, which are mostly well separated from each other In a band spectrum, a great number of fine lines—called band lines—are closely crowded together in each band, especially near the so-called head of the band, so that they can only be separated with comparatively powerful instruments The difference may be best understood by reference to the photographs of portions of the line and band spectra of nitrogen which are reproduced in Plate I., 1a and 1b A succession of bands with well-marked heads, as in nitrogen, gives a fluted appearance to the spectrum, and bands of this kind are often called *flutings* There are other bands of less regular appearance, and others which do not appear to be resolvable into lines Line spectra are characteristic of atomic emissions, while band spectra originate in molecules. (*See* BAND SPECTRA.)

Absorption Spectra.—In contrast to emission spectra there is another class of spectra known as *absorption spectra* A piece of glass which appears red by transmitted light owes this appearance to its property of transmitting red light and of absorbing the light of other colours of which white light is composed (*See* COLOUR) Such a piece of glass gives continuous absorption over a certain range of the spectrum, while a piece of neutral-tinted glass exhibits a partial continuous absorption throughout the whole of the visible spectrum There are, however, many substances which, at ordinary temperatures, give characteristic absorption bands by which they can be identified Among solid substances, glass coloured with salts of neodymium shows a beautiful set of dark bands when white light is passed through it before entering the slit of the spectroscope (*See* Plate I, 2a) Solutions of permanganate of potash, chlorophyll, blood and of many aniline dyes similarly show absorption bands which are characteristic in each case Several gases and vapours in a non-luminous state at ordinary or moderate temperatures also yield absorption spectra peculiar to themselves Iodine vapour, produced by slightly warming crystals of iodine in a test-tube, and nitrogen peroxide are good examples. Oxygen and water vapour similarly show their presence in our atmosphere by the appearance of their characteristic low-temperature absorption bands in the spectrum of sunlight.

Absorption spectra are also given by gases and vapours in a luminous state, when they are placed in the path of the rays from a white source at a higher temperature Kirchhoff's famous experiment of 1859 proved that a luminous vapour has the property

of absorbing precisely the same kind of light that it emits at the same temperature; so that if such a vapour (a sodium flame, for example) lies in front of a source at a higher temperature, and giving a continuous spectrum, the result is a continuous spectrum crossed by dark lines. An example of absorption is shown in Plate I., 2b, which represents the absorption of the vapour in a heated tube containing potassium. This result is of fundamental importance in Astrophysics because the spectrum of the sun and the spectra of most of the stars show dark lines or bands on a bright continuous background. The experiment of Kirchhoff proves that the substances which produce such dark lines can be identified, just as surely as if the lines were bright, by the process of matching the dark lines by emission spectra produced in the laboratory.

SOURCES FOR SPECTROSCOPIC OBSERVATION

While any luminous body is a suitable subject for spectroscopic investigation, there are several methods of exciting substances to luminosity which are especially convenient, or are of a character to give valuable information about the emitting atoms or molecules. Apart from the spectra of gases, and such phenomena as fluorescence, the three chief sources employed in a laboratory are the bunsen or oxyhydrogen flame, the electric arc and the electric spark. In general, the same substance will show differences in its spectrum when examined in these different ways, but some lines are usually common to the three sources. Lines which occur in the flame are distinguished as flame lines, but only those which have their greatest intensity in the arc are properly called arc lines; lines which are more strongly developed, or only appear, in the spark are called spark lines. The spark lines thus defined are the "enhanced lines" of Sir Norman Lockyer, and the distinction is now of great importance. In the language of modern spectroscopy, flame lines are the more easily excited lines of the neutral atom in question, while the arc usually exhibits the complete spectrum of the neutral atom together with the more easily excited lines of the ionized atom; the spark gives a special development of the lines of the ionized atom, besides retaining the more persistent lines of the neutral atom. Portions of the spark and arc spectra of strontium are shown in Plate I., 3a and 3b; it will be seen, for example, that the line at λ4,607, which is a flame line, is reduced in intensity in the spark, while the enhanced lines at λ4,078 and λ4,216 are relatively much intensified in the spark.

Flames.—The simplest procedure for the observation of flame spectra is to make use of a bunsen burner, and to introduce the various substances to be studied by means of a platinum wire, or on the charred end of a match. This method suffices to give spectra of the alkali and alkaline earth metals, and of thallium salts, as well as of numerous compounds such as copper chloride.

At the relatively low temperature of flames a large number of substances give banded spectra, as the molecules of the elements or compounds introduced are only partially dissociated into their component atoms. Some of these bands are due to oxides which are produced in the flame.

The Electric Arc.—A very valuable source for the observation of spectra is the electric arc, which, besides the advantage of great luminosity, will fuse and volatilize any substance which may be introduced between the poles. For the investigation of metallic spectra it is best to use poles made of the metals themselves, if they do not melt too readily, in order to avoid contamination. In general, however, some of the substance is placed on the lower (positive) pole of the carbon arc. The bands of the Swan spectrum of carbon and those of cyanogen which are given by the carbon itself would often be troublesome but for the fact that they tend to disappear if a sufficient amount of material be introduced. Lines due to impurities in the carbon rods can be distinguished by observing or photographing the spectrum before the introduction of the substance under examination. Acheson graphite rods can often be used with advantage, as the impurities are usually very slight. Rods of pure silver have also been used as a means of supporting the substance.

The appearance of so-called "reversed lines" in arc spectra is quite common. This is accounted for by a broadening of a line from the denser vapour in the core of the arc, and the superposition upon it of a narrower absorption line produced by the cooler and less dense vapour in the surrounding region.

It should be further noted that different parts of an arc show considerable variations in spectrum. The fully developed arc spectrum is restricted to the central core, while the surrounding "arc-flame" yields a spectrum corresponding to a lower temperature. The arc-flame may, in fact, often be conveniently used in place of the oxy-hydrogen flame. These differences are readily observed when an image of the arc is focussed on the slit of the spectrograph. By the same method it may be observed, more especially when the poles of the arc are metallic, that certain lines only appear, or are better developed in the immediate neighbourhood of the poles; these are the so-called "polar lines," and are generally found to be lines which are more strongly developed in the spark.

There is also a peculiar slight disturbance in the positions of some of the lines near the poles of an arc, called the "pole effect," which makes it necessary to establish a standard source when the iron arc is used to provide standards of wave-length. In the "Pfund arc," which has been recommended by the International Astronomical Union, the anode is below and consists of a bead of iron oxide supported on a massive rod of iron, while the cathode above is a rod of iron 6–7 mm. in diameter, having a massive cooling cylinder of copper or brass close to the end of the rod. The current may be five amperes or less at 110–250 volts, and the arc 12–14 mm. in length. Only the central zone at right angles to the axis of the arc, not exceeding 1½ mm. in width is to be used.

The "vacuum arc" is an important modification of the ordinary arc in which the arc is enclosed in a vessel which can be exhausted. Under these conditions the spectrum tends to approach that given by the spark, and the lines are very sharply defined. The same arrangement may also be used for passing the arc in any desired gas, such as hydrogen.

The Electric Spark.—The luminosity for observations of spark spectra is usually produced by discharges from an induction coil between terminals made of the substance to be examined, or between terminals of platinum on which the substance is supported. Transformers suitable for the purpose are also available. As shown in fig. 6, a Leyden jar or other condenser, J, is connected in parallel with the leads A and B from the coil to the terminals, S, which are separated by only a few millimetres. Without this condenser, the luminosity is very feeble and the spectrum consists almost entirely of bands of nitrogen.

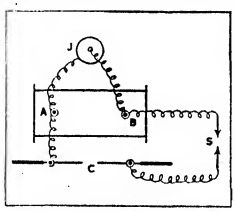

FIG. 6.—THE ELECTRIC SPARK

The intensity of the discharge can be greatly varied by making use of an auxiliary spark gap, shown at C in fig. 6; the longer this gap the greater the potential to which the condenser must be charged before the discharge will pass.

The condensed spark yields lines special to the substance under examination, and, in addition, lines due to atmospheric nitrogen and oxygen. The air lines are common to all the spectra observed in this way and can therefore readily be identified as such. Air lines can also be eliminated by passing the spark in a closed vessel containing hydrogen, the spectrum of which is much simpler than that of air. The spectra of gases surrounding the spark can be abolished altogether by introducing a self-induction coil in series with the spark, as between C and S in fig. 6, in accordance with the investigations of Schuster and Hemsalech.

Vacuum Tubes.—The spark discharge as described above can clearly be used to obtain the spectra of gases. Under these conditions, however, the gas lines are mostly too broad for accurate measurement, and observations are accordingly more generally

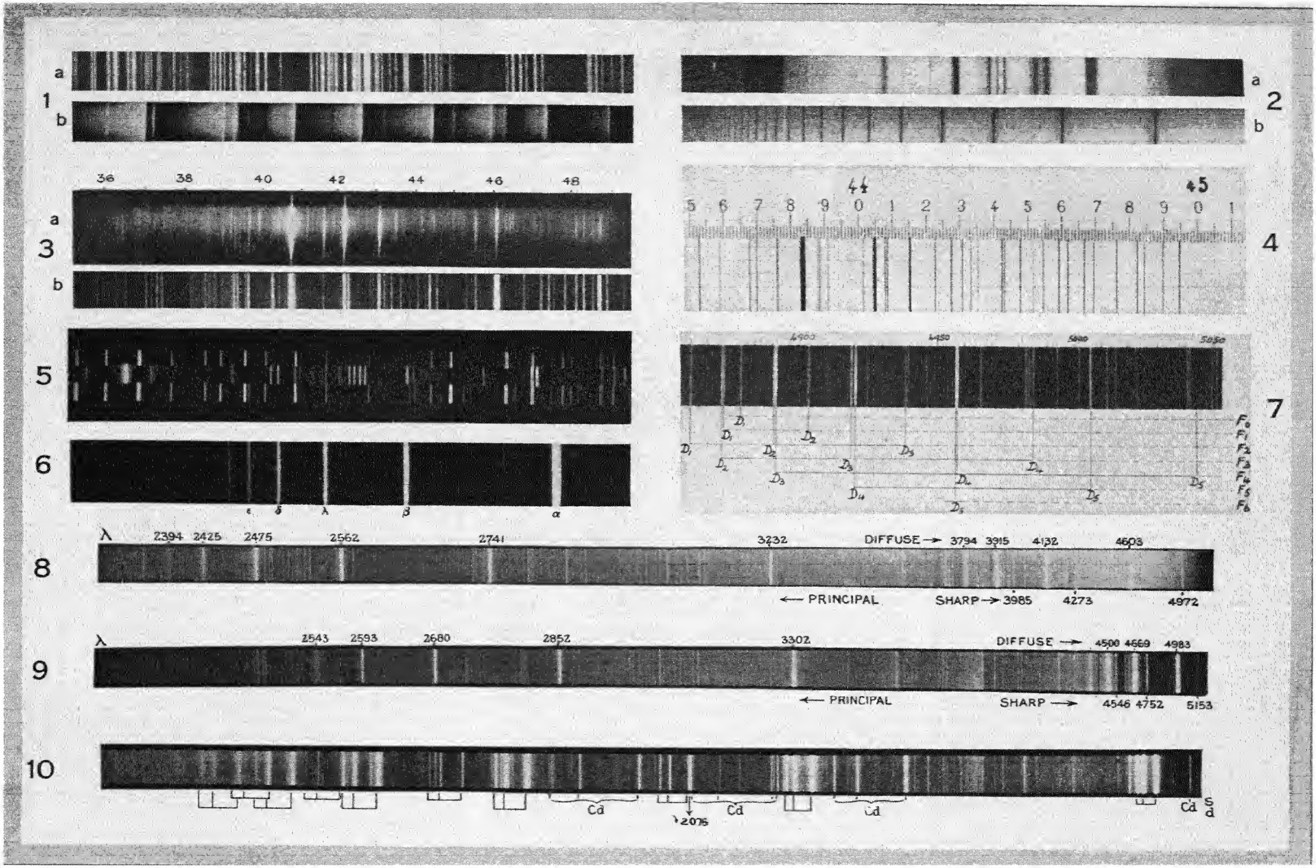
SPECTRA ON A QUARTZ SPECTROGRAPH

1. Spectrum on a quartz spectrograph with a metallic arc giving plenty of lines in the ultra-violet as follows: the top line shows quartz spectrograph without anything in it; 2nd line, with Vita glass; 3rd line, with plate glass; 4th line, with optical crown glass; 5th line, with dense flint optical glass; 6th line, with Wood's glass
2. Another set of spectrographs with: top line, metallic arc; 2nd line, solar spectrum; 3rd line, solar spectrum with Vita glass; 4th line, solar spectrum with plate glass
3. A third set of spectrographs with: top line, metallic arc; 2nd line, blood; 3rd line, carbon disulphide

SPECTROSCOPY



BY COURTESY OF (3, 8, 9, 10) THE PHYSICAL SOCIETY FROM FOWLER, "REPORT ON SERIES"

SELECTED PORTIONS OF TYPICAL SPECTRA

1. Spectra of nitrogen; (a) line spectrum, (b) band spectrum. 2. Absorption spectra; (a) neodymium glass, (b) potassium vapor. 3. Spectra of strontium; (a) spark, (b) arc. Flame lines are reduced in intensity in the spark spectrum, while "enhanced" or "spark" lines are intensified. 4. Photographic map of iron-arc spectrum, from which approximate light wavelengths may be obtained. 5. Spectra of iron and oxygen (middle), placed in juxtaposition for comparison. 6. "Red" spectrum of hydrogen, showing Balmer series of lines peculiar to this element in the visible and near ultra-violet regions. 7. Arc spectrum of iron, under high dispersion, showing a multiplet of 15 lines which make up what is apparently a single line in more moderate dispersions. 8. Arc spectrum of lithium. Numbered lines, apparently single, are doublets. 9. Arc spectrum of sodium, similar to that for lithium. The terms principal, sharp, and diffuse refer to the appearance of the numbered lines indicated. 10. Arc spectrum of zinc and cadmium, showing triplet systems

made with the gases at reduced pressures in so-called "vacuum tubes." Such tubes are made in great variety according to the object of the experiments undertaken. Fig. 7a represents a form called the Geissler or Plücker tube, which can be purchased ready prepared for spectroscopic examination. It consists of two glass tubes of about three inches in length and half an inch in diameter, connected by a short length of capillary, and having a platinum

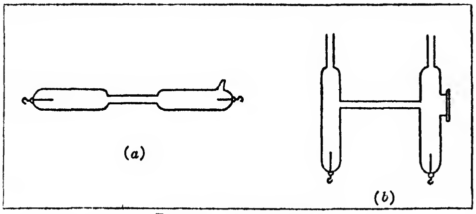


FIG 7 —GEISSLER TUBES

wire sealed in at each end The tube is exhausted and the desired gas admitted through a side tube, which is sealed off with a blow-pipe when suitable conditions are established When the electrodes are connected with an induction coil, a bright discharge passes through the tube, varying in colour and spectrum with the gas which has been introduced The discharge is especially brilliant in the capillary tube, where the current density is greatest, and the spectrum shown by this is usually different from that given by the wider parts of the tube. The spectrum of the same gas also varies according as the discharge is passed with or without a condenser in the secondary circuit, the changes being comparable with those observed in passing from arc to spark.

Another common form of tube is shown in fig 7b; this is designed to give an "end on" view along the capillary, and since glass is not transparent to ultra-violet light, a side tube with a quartz window is often added as shown in the diagram. With this form of tube the spectrum appears with greater intensity Sometimes the whole vacuum tube is made of fused silica glass In most experimental work, the vacuum tubes are not sealed, but remain in connection with the exhaustion pump and the source of the gas under investigation, so that the pressure and other conditions can be conveniently controlled Much care is necessary to obtain pure gases in the tubes.

When mixed gases are under examination, it frequently happens that a particular discharge will not produce spectra of all the gases present. Thus, an uncondensed discharge through a vacuum tube containing residual air will show the bands of nitrogen but will give no indication that there is any oxygen in the tube. Both gases, however, are revealed by their line spectra when the condensed discharge is passed through the mixture. In analysing a mixture of gases it is accordingly necessary to observe the spectrum under varying conditions of electrical discharge, and variations of pressure are also desirable.

Other Sources.—The methods of exciting substances to luminosity above described provide the observer with a wide range of exciting energies, but numerous additional methods have also been adopted Thus, the electric furnace, in the form of a carbon tube heated by heavy electric currents, has been very effectively employed by A. S. King at the Mount Wilson laboratory. In this way the temperature of the emitting vapour is well under control and the order of appearance of the lines is a valuable aid in investigations of the structure of the spectrum. Interesting results have also been obtained by King with arcs in air using a current of the order of 1,000 amperes at 100 volts. Similar experiments by J. W. Ryde, with currents up to 250 amperes, have been of special value in revealing with great intensity the line spectra of neutral carbon and nitrogen, which were previously only partially known. Our knowledge of these spectra had previously been considerably extended by T. R. Merton by observations of carbon compounds, or of nitrogen, when mixed with a large proportion of helium. A further application of Merton's method, though better results were obtained with argon admixture, was made by J. C. McLennan and G. M Shrum in experiments on oxygen which led them to their important discovery that a line of neutral oxygen observed under these conditions was identical in position with the green line which is most characteristic of the spectrum of the aurora.

SPECTROSCOPIC MEASUREMENTS

The need for some means of expressing the positions of lines in the spectrum is sufficiently evident. In the more common forms of spectroscope the observing telescope is provided with cross-threads which can be brought into coincidence with any given spectrum line, and the position of the telescope is then read off on a graduated circle. Such readings will evidently give the relative positions of the lines on an arbitrary scale, but readings for the same lines on different instruments will not be directly comparable. Similarly, when dealing with photographs it is only possible to measure directly the relative positions in arbitrary units.

Wave-lengths.—Measurements of spectra which have been observed or photographed become directly comparable with each other when they have been converted to the scale of wave-lengths of the light which produces them The credit of introducing this scale into spectroscopy is due to A. J. Ångstrom, who mapped the spectrum of the sun in terms of wave-lengths in 1868. The same procedure was subsequently adopted by his colleague Thalén in connection with the spectra of the elements, and since that time the positions of spectrum lines in all spectroscopic tables have been stated in wave-lengths The unit of wave-length in spectroscopy is the ten-millionth of a millimetre, or 10^{-8} centimetre It is called the tenth-metre (10^{-10} m) or "angstrom," and is now ordinarily indicated, when necessary, by writing A after the figures indicating the wave-lengths In these units, the visible spectrum ranges from about 3,900A at the violet limit to about 7,600A in the extreme red. When it is stated, for example, that the wave-length of the red line of hydrogen is 6,562·79A, it is to be understood that it amounts to $6{,}562{\cdot}79 \times 10^{-8}$ cm. Wave-lengths, especially in connection with the invisible infra-red part of the spectrum, are also often expressed in terms of the *micron* (μ), which is one-thousandth of a millimetre; thus the wave-length of the red hydrogen line might be written 0 656279μ.

Absolute wave-lengths cannot be determined directly by the use of prisms, but are determined by observations made with diffraction gratings or by interference methods. In ordinary spectroscopic work, however, whether with prisms or gratings, no attempt is ever made to determine the wave-lengths directly. The wave-lengths required are deduced by interpolation between standard lines which have previously been determined with sufficient accuracy.

Wave-numbers.—More especially in connection with investigations of regularities in spectra it is important to express the positions of spectrum lines in "wave-numbers" instead of in wave-lengths. The most fundamental figures in this connection for theoretical purposes are the "oscillation frequencies," since these are independent of the medium through which the light passes. Oscillation frequency may be defined as the number of waves which pass a given point in one second, and is equal to the velocity of light (c) divided by the wave-length (λ) in vacuo, i.e , $n = c/\lambda$ Since the velocity of light is very great (nearly 300,000 kilometres per second), and the wave-lengths very small, oscillation frequencies are represented by extremely large numbers. Thus, for red light of wave-length 6,500A the frequency is about 462 billions per second, while for violet light of wave-length 4,200A it is 713 billions per second Difference in colour, it will be noticed, depends upon difference in the frequency of the waves that reach the eye. These oscillation frequencies are not directly measurable but can be deduced from the measured velocity of light combined with measurements of wave-lengths. They are unsuitable for ordinary spectroscopic use on account of their great magnitude It is accordingly the practice to replace the actual frequencies by "wave-numbers," representing the numbers of waves in the length of a centimetre. Since the

wave-number is dependent on the wave-length, it will vary with the medium in which the vibrations are propagated, and in the calculation of wave-number from wave-length it is therefore necessary to express the wave-length *in vacuo*. If a wave-length has been measured in air it must be corrected to vacuum conditions for the determination of the corresponding wave-number. This correction is based upon measurements of the refractive index of air for different wave-lengths, and convenient tables have been prepared for its application. When corrected to vacuum in this way the calculated wave-numbers are strictly proportional to the corresponding oscillation frequencies.

Standard Wave-lengths.—The primary standard of wave-length in modern spectroscopy is based upon interferometer measurements of the red line of cadmium, under standard conditions, in relation to the standard metre. The unit of wave-length thus arrived at is called the International Angstrom, and is very close to 10^{-10} metre. The standard conditions are air at 15° C and 760 mm. pressure, $g=980{\cdot}67$, and the wave-length of the red cadmium line, adopted by international agreement, is then 6,438·4696I.A. This has been deduced from the work of C. Fabry and A. Perot, and is in close agreement with the value determined by A. A. Michelson. (*See* INTERFEROMETER.) The older spectroscopic tables are on the scale of Rowland, which was based upon slightly erroneous absolute wave-lengths for the two yellow lines of sodium; such tabulated spectra can be approximately corrected to the international scale by subtracting quantities ranging from 0·25 at 7,000A to 0·06 at 1,950A.

The most useful secondary standards, especially for work with large instruments, are provided by the arc spectrum of iron, which includes many hundreds of lines. Many of these have been measured with respect to the red cadmium line in various laboratories, and a number of secondary standards for general use have been recommended by the International Astronomical Union (*Transactions*, vol. III., 1929).

Interpolation of Wave-lengths.—The secondary standards, which have thus been determined by interferometer methods may obviously be used for the determination of the positions of lines in any other spectra by interpolation, employing ordinary spectrographs. For this purpose, photographs are taken of the source under examination through one portion of the slit, and an arc spectrum of iron through one or both of the adjacent portions, so that two spectra in juxtaposition, or slightly overlapping, are obtained as illustrated in Plate II., fig. 5. Lines of other elements thus become, in turn, available for use as tertiary standards, and may be used with instruments which give too small a dispersion to resolve satisfactorily the complicated spectrum of iron.

When a prismatic spectrum is used, the dispersion increases rapidly as the wave-length diminishes, and simple linear interpolation between standards will not give correct results. When the spectra do not permit of very accurate measurement, the interpolation may be performed graphically, using measurements of the lines under investigation and a number of lines of known wave-length in conjunction. The same procedure may be adopted for measurements of a photograph with a finely divided scale, if a comparison spectrum which includes lines of known wave-length has also been impressed on the plate, or if a sufficient number of known lines are included in the spectrum under examination.

For more accurate determinations, photographs are measured with a photo-measuring micrometer. This consists of a microscope of moderate or low power which can be made to traverse the photograph by means of an accurate screw of small pitch, so that the cross-threads are brought successively into coincidence with the desired lines; the positions of the lines are then read off on a scale which counts complete turns of the screw, and a divided drum head which registers fractions of a turn. As before, lines of known wave-length, which are generally provided by a comparison arc spectrum of iron, must be included in the measurements. Interpolation may then be most conveniently performed with the aid of a formula first proposed by A. Cornu and afterwards brought into more general notice by J. Hartmann. The wave-length, λ, and the scale reading, s, are here supposed to be related by the hyperbolic formula

$$\lambda=\lambda_0+C/(s+s_0).$$

Three lines of known wave-length, and the corresponding scale readings are thus required in order to determine the constants λ_0, C and S_0; one should be chosen near each end, and the other near the middle of the region investigated.

The wave-lengths so determined will not be quite exact, because the formula does not accurately represent the dispersion of the spectrum on the plate, except over a small range. The imperfection of the formula, however, can be corrected by including a number of well distributed known lines in the measurements. The differences between the calculated and known values of these lines are then plotted to give a "curve of errors," which can be used to give the corrections to the calculated wave-lengths of the lines under observation. This procedure might, of course, be adopted with any approximate formula, but the Cornu-Hartmann formula has the advantage that the corrections are small.

The dispersion in spectra produced by gratings is much more uniform—that is, the spectra are more nearly *normal*—than in those produced by prisms. By certain arrangements, the scale of a grating apparatus can be made quite normal for visual observations, but in all photographs there is a slight departure from a uniform scale. Interpolation may then be made by following the procedure which has been outlined for prismatic spectra, except that the Cornu-Hartmann formula is replaced by a linear interpolation formula, such as $\lambda=\lambda_0+bs$, where λ_0 and s can be calculated from two of the standard lines which are included in the measurements. The necessary corrections for lack of normality are then given by a curve of errors similar to that described for prismatic spectra.

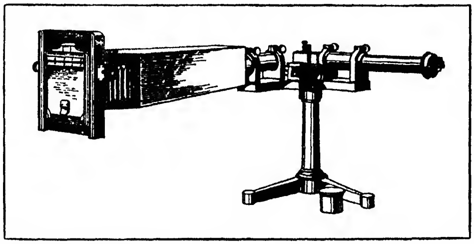
A good photographic map of the iron arc spectrum, which is indispensable in practical spectroscopy, has been prepared by C. Fabry, ranging from λ2,327 to λ6,700. A small portion of this is reproduced in Plate II., fig. 4; approximate wave-lengths can be read off from the map and the corresponding accurate wave-lengths obtained from tables.

PHOTOGRAPHIC SPECTRA

Spectroscopic work of precision is now almost invariably carried on by photographic methods. A photographic record of a spectrum has many obvious advantages; it can be examined as often as desired by any number of persons without the need for repeating the experimental arrangements, and it can be more conveniently and more accurately measured. Moreover, with appropriate instruments, the invisible ultra-violet part of the spectrum can be included in the photographic record, and by the use of specially prepared photographic plates a considerable portion of the near infra-red region, extending as far as λ10,000A or 1μ, can also be photographed. The additional region in the ultra-violet thus opened up is of considerable importance from the point of view of spectrum analysis, and both regions are of great significance in connection with investigations of the structure of spectra. The photographic plate has a further important advantage arising from the power of integrating successive impressions, whereas the eye can only take account of momentary effects on the retina; spectra which are too faint for satisfactory direct observation may thus be made available for investigation by photographs taken with long exposures.

Spectrographs.—In their optical arrangements, spectrographs are similar to the spectroscopes intended for visual observations. It is, in fact, only necessary to replace the observing telescope by a camera provided with a suitable object glass as shown in fig. 8. If the object glass of the telescope itself were utilized and the spectrum could be photographed on a perfectly transparent plate, it will be clear that when viewed with the eyepiece as magnifier, the spectrum would be identical with that directly observed, apart from the absence of colour. Photographic plates, however, have a granular structure and lines which might be just separated visually would not appear separated on the plate. Thus, to obtain a photographic resolution equivalent to the visual, it is necessary to use a camera lens of considerably greater focal

length than that of the ordinary telescopic objective, so that the spectrum may be magnified before it reaches the photographic plate. It is desirable, though not essential, that the collimating lens should have a focal length not very different from that of the camera lens, and with the ordinary construction such instruments are apt to be unwieldy. Long focus spectrographs are accordingly now most frequently built up on the plan suggested



BY COURTESY OF HILGER

FIG. 8.—A SIMPLE SPECTROGRAPH

by Littrow. In this form the same lens serves as collimator and camera lens, and light passing through the prism is returned along the same path either by a plane mirror behind the prism, or by a half-prism silvered on the back, as shown in fig. 9 In such an instrument the slit, S, is placed at the side and light entering it is directed along the axis of the lens by a small reflecting prism *p*, and it is easy to arrange matters so that the spectrum enters a narrow aperture in the camera at P just above the level of the reflecting prism The Littrow arrangement has the advantage that each dispersing prism acts as two prisms, and in addition, the instrument may be made of great rigidity.

Since there is nothing on a photographic plate to indicate the wave-lengths of any of the lines, except that many lines can be identified by their peculiar groupings, it is usually necessary to

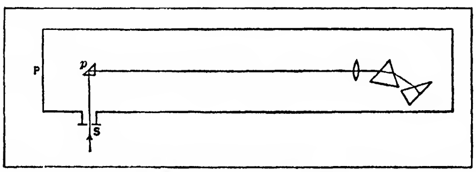


FIG. 9—LITTROW SPECTROGRAPH

photograph a known spectrum, which has already been accurately measured, in juxtaposition with that under observation.

The Infra-Red.—Since glass is not transparent to the ultra-violet and infra-red rays, or only to a small extent, prisms and lenses made of other substances are requisite for the exploration of these parts of the spectrum. Prisms of rock salt, which are largely used for the infra-red, will transmit as far as wave-length 150,000A, or 15μ, whilst a fluorite prism will transmit as far as 9μ, and one of sylvine as far as 23μ. To reduce loss of intensity by absorption, concave mirrors are used in place of lenses for collimation and image formation. A delicate thermopile, which is connected with a highly sensitive galvanometer, reveals the presence or absence of spectrum lines as the spectrum is moved across it by rotating the prism. Readings on the scale of the prism table are then convertible to wave-lengths with the aid of standards which have been determined by the use of gratings. By the use of a large concave grating in place of a prism, F. Paschen has measured many spectra as far as $3{\cdot}1\mu$. With the aid of Eastman Kodak's neocyanine and kryptocyanine plates, the infra-red spectrum can now be directly photographed as far as 1μ.

The Ultra-Violet.—As regards the ultra-violet, which may be considered to begin at about λ3,900, prisms of light flint glass will transmit to the neighbourhood of λ3,300, while prisms of the so-called *uviol* glass will extend this to about λ 2,900. Beyond this, if prisms are used, it is necessary to construct them from natural crystals, usually Iceland spar or quartz, and principally the latter. With an instrument built up from prisms and lenses of quartz, it is possible to photograph as far as about 2,100A with ordinary plates and to about 1,840A with specially prepared plates. It is in fact possible to *see* the whole of this part of the spectrum by allowing it to fall on a fluorescent screen such as is used in X-ray observations. The need for special plates for the most refrangible part of this region is due to the fact that gelatine absorbs the short waves before they can reach the sensitive salts which are embedded in it. An extremely useful method is that introduced by Duclaux and Jeantet, in which an ordinary plate is coated with an oil, such as paraffin, or nujol, which becomes fluorescent under the stimulus of ultra-violet light so that the spectrum is actually photographed in light of longer wave-length; when this method is applied the oil must be removed, as by washing the plate with benzene, before development. Plates prepared by Schumann's method, in which the gelatine is reduced to the smallest quantity that will allow adherence of the silver salts to the glass, however, are the most suitable for the extreme ultra-violet. Such plates are now prepared commercially by the firm of Adam Hilger, Ltd, London.

As quartz has the property of double refraction, it is necessary to cut prisms of this material so that the optic axis of the crystal is at right angles to the refracting edge and parallel to the base. Even then, however, there would be a slight doubling of the spectrum lines arising from the property of quartz by which it rotates the plane of polarization. This is overcome by Cornu's device (fig 10) in which one half of the prism is made from right and the other from left-handed quartz. The two lenses in a quartz spectograph are also of opposite rotations, and in order that a long range of spectrum may be in good focus, the photographic plate must be inclined to the axis of the camera, and bent to an appropriate curve in the plate-holder.

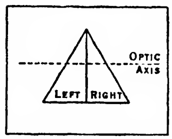

FIG. 10.—CORNU PRISM

The Schumann Region.—For wave-lengths still shorter than 1,840A, fluorite is the most useful substance at present known. With prisms and lenses of this material it is possible to photograph as far as 1,200A, providing that Schumann plates are used and that the absorption of air is eliminated by exhausting the spectrograph and allowing no air to intervene between the source and the slit. Victor Schumann was the first to investigate by this method and the region from 1,850A to 1,200A is conveniently called the Schumann region Even one millimetre of air at atmospheric pressure will absorb all light of wave-lengths less than about 1,700A. Among the sources which are available for investigations in this region, the slit being covered with a thin plate of fluorite, are the "vacuum arc" (an electric arc in an exhausted vessel), the spark in an atmosphere of hydrogen (this gas being transparent for short waves), vacuum tubes, and the "vacuum spark" of Millikan and Bowen in which short sparks are produced by heavy discharges between terminals in a high vacuum In each case, the vessel containing the source is sealed to the slit plate of the instrument.

The Extreme Ultra-Violet.—The region of the spectrum lying beyond the limit set by fluorite can at present only be investigated by the use of concave diffraction gratings, in which no lenses are used, and the path of the rays from the source to the photographic plate is entirely *in vacuo*. With such instruments the spectrum has been photographed as far as 136A by Millikan and Bowen, and the region beyond this—the soft X-ray region—has been photographed by Jean Thibaud, using a grating near grazing incidence.

CHEMICAL ANALYSIS BY THE SPECTROSCOPE

Qualitative Analysis.—Spectroscopic methods provide an important aid to chemical analysis, especially when an element is present only in small proportion, or when only a small quantity of a substance is available for examination. The principles involved in qualitative analysis are embodied in what has been

stated before, and it is only necessary to add a few supplementary remarks. In the first place, it should be understood that although refined measurements extending over the greatest possible range of spectrum, and including spectra emitted under very varied conditions, are necessary for exhaustive investigations of the structure of spectra, the procedure for purposes of chemical analysis is much simpler. Such analysis can, in fact, be carried on to a considerable extent without any attempt at precision in the determination of wave-lengths by either visual or photographic methods.

For visual observations with an ordinary spectroscope, the graphical method of interpolation is sufficiently accurate for the identification of many spectrum lines. It is more convenient, however, to use a wave-length spectrometer, in which the scale is so constructed that wave-lengths of fair accuracy can be read off directly. Then again, familiarity with the spectra of various elements often enables an experienced observer to identify lines at sight; for, in addition to the help given by colour, lines frequently occur in groups which can be identified in the same way that constellations are recognized among the stars.

An iron arc spectrum is photographed beside the spectrum under investigation, and estimates of wave-length, accurate enough for purposes of identification, can be made by reference to the scale on a wave-length map of the iron spectrum. If the spectrum is a complicated one, and some of the constituent elements have been identified in this way, it is convenient to take additional photographs with these elements as comparisons. Measurements and calculations of wave-lengths are then necessary only for the lines which remain unidentified. As the most sensitive lines of many of the elements lie in the ultra-violet, a quartz spectrograph is usually the best instrument for chemical applications.

It is sometimes convenient, or necessary, to analyse solutions by the spectroscopic method. If the electric arc be employed, it is generally sufficient to soak the tips of the carbon poles in the solution before striking the arc. It is usually more satisfactory, however, to use the condensed spark, in which case the lower electrode may be formed by a bundle of fine platinum wires standing in the liquid and projecting slightly above its surface, while the upper electrode is a stouter piece of platinum wire.

For the analysis of refractory substances, such as silicates, the method introduced by A. de Gramont gives excellent results. The substance is first fused with four or five times its weight of sodium or lithium carbonate, and is placed in a small platinum cup which forms the lower electrode for the passage of a condensed spark. The cup is heated by a bunsen flame while the discharge passes. In photographic work, the spectrum of the fusion material would naturally be photographed separately, so that its contribution to the final spectrum could easily be recognised.

Abridged tables of spectra, including the brightest and most sensitive lines of the various elements, have been compiled to facilitate chemical identifications. (*See* Bibliography.)

Quantitative Analysis.—Several of the earlier workers with the spectroscope were attracted by the possibility of discovering methods by which spectrum analysis might yield quantitative results. Such methods as were proposed, however, were too restricted in their application, or subject to too many experimental uncertainties, to be of much practical service. The advance in the theory of spectra has somewhat improved the outlook, but even now the most successful methods are of limited application and of an entirely empirical character.

The most systematic efforts to establish a procedure for quantitative analysis are probably those made at the United States Bureau of Standards by W. F. Meggers and others (*Scientific Papers*, No. 444). The method is based partly on the work of de Gramont, who made a prolonged study of the so-called *raies ultimes* of the elements, these being the last lines to disappear as the proportion of an element in a mixture is reduced towards the vanishing point. As an example of the procedure adopted, the method of estimating a small percentage impurity of zinc in tin may be considered. A graded series of alloys is first prepared, of tin containing zinc in the proportions 0·001, 0·01, 0·1, 1·0, and 10·0 per cent., and their spark spectra are compared under identical conditions. The lines of zinc will obviously increase in intensity with respect to those of tin as the quantity of zinc increases, and the correlation of the intensities with the known percentage composition of the specimens provides a scale for the analysis of similar alloys of unknown composition. Similar methods have been successfully employed in the quantitative analysis of samples of gold and platinum, and give promise of useful application in numerous problems of practical importance.

DISPERSION AND RESOLVING POWER OF PRISMS

Dispersion.—The dispersion at any point in the spectrum is defined as the rate of change of the angle of deviation with respect to a small change in the wave-length. Thus, if θ be the angle of deviation from the original path of the light, the dispersion is represented mathematically by $d\theta/d\lambda$. Since θ varies with the refractive index of the glass (μ), and the refractive index varies with the wave-length (λ), we may write

$$\text{Dispersion} = d\theta/d\lambda = d\theta/d\mu \cdot d\mu/d\lambda.$$

Dispersion thus depends upon two factors. The second, $d\mu/d\lambda$, depends solely upon the optical properties of the glass of which the prism is composed and may be calculated from observations of the refractive indices for different wave-lengths, when expressed in a formula. If the refractive indices be approximately represented by an equation of the form $\mu = a + b/\lambda^2$, the constants a and b being deduced from measured values of μ for different wave-lengths, $d\mu/d\lambda = -2b/\lambda^3$. The negative sign merely implies increase of μ with decrease of λ, and it follows from the formula that the dispersive power varies roughly in proportion to the inverse cube of the wave-length. For example, the dispersion at λ3,500 in the near ultra-violet is about eight times that at λ7,000 in the extreme red.

The other factor in the expression for the dispersion of a prism, $d\theta/d\mu$, depends upon the angle of the prism, and on the way in which it is presented to the incident light. If, as in fig. 11a, the angles of incidence and emergence be represented by i_1 and i_2, the internal angles of refraction by r_1 and r_2, the angle of the prism

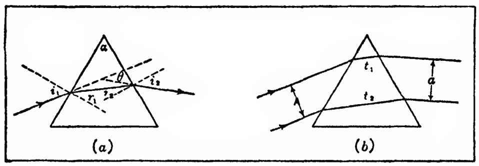

FIG. 11.—DISPERSION AND RESOLVING POWER OF PRISM

by α, and the angle of deviation by θ, it is readily deduced from the fundamental relation $\sin i = \mu \sin r$ that

$$\frac{di_2}{d\mu} = \frac{\sin(r_1 + r_2)}{\cos r_1 \cos i_2}$$

or, since $d\theta = di_2$, and $r_1 + r_2 = \alpha$,

$$\frac{d\theta}{d\mu} = \frac{\sin\alpha}{\cos r_1 \cos i_2}.$$

This expression clearly shows the dependence of the dispersion on the angle of the prism and the angle of incidence, but, following Lord Rayleigh, a very convenient geometrical equivalent can be deduced; namely,

$$\frac{d\theta}{d\mu} = \frac{t_2 - t_1}{a}$$

where t_2 and t_1 are the lengths in the prism traversed by the extreme rays, and a is the breadth of the emergent beam. When the prism is at minimum deviation and the beam is large enough to cover it, $t_2 - t_1$ is equal to the length of base of the prism. The whole dispersion may now be written,

$$\text{Dispersion} = \frac{d\theta}{d\lambda} = \frac{t_2 - t_1}{a} \cdot \frac{d\mu}{d\lambda}.$$

The same expression can also be deduced directly by an application of Fermat's principle of optical distances.

When there is more than one prism, the sum of the values of t_2-t_1 is to be taken, and in direct vision of compound prisms, the algebraical sum is taken, the crown glass prisms being regarded as negative.

Resolving Power.—The power of separating closely adjacent spectrum lines is called the resolving power of the prism. (*See* LIGHT) As now employed this is a theoretical quantity, representing the separating power when the slit is indefinitely narrow, and is given numerically by $R=\lambda/d\lambda$, where $d\lambda$ is the difference of wave-lengths of two lines which can just be divided. R does not increase indefinitely as the slit is narrowed, because the image of the slit is broadened by diffraction The actual image is a diffraction pattern, as roughly shown, with the corresponding intensity curve in fig 12. Most of the light is concentrated in the central band, and the secondary bands can be disregarded If f be the focal length of the camera lens, and a the effective breadth of the beam passing through it (the effective beam being supposed of rectangular cross section) the half-breadth (ρ) of the central band is given by the elementary theory of diffraction as $\rho=f\lambda/a$. It is to be observed that the shorter the wave-length the narrower is the band, while a reduction of aperture is accompanied by a broadening

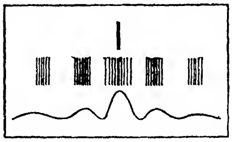

FIG. 12.—DIFFRACTION IMAGE OF A SLIT

The condition for resolution may be conveniently explained by reference to fig. 13, where the spectrum is supposed to be thrown on a screen by the second lens. The wave-lengths of two closely adjacent lines from light entering the slit at s being λ and $\lambda-d\lambda$, the corresponding separation by the prism is $d\theta$. Each line appears as a diffraction band, of which the intensity curves are shown, and resolution is just effected when the maximum of one band falls on the minimum of the other, that is, when the distance between the centres of the two bands is ρ. Under these conditions the integration of the two bands gives a curve with two maxima and if the intensity of these be taken as unity, that of the minimum between is 0·8. Experience has shown that this difference is sufficient to resolve lines, and the condition for resolution is thus $d\theta=\rho/f_2=\lambda/a$; or, $\lambda=a\ d\theta$ In this expression, it should be remembered, a is not necessarily the diameter of the image lens, but the effective breadth of the beam which enters it By definition, $R=\lambda/d\lambda$ and we thus find $R=a\cdot d\theta/d\lambda$, or in Rayleigh's form,

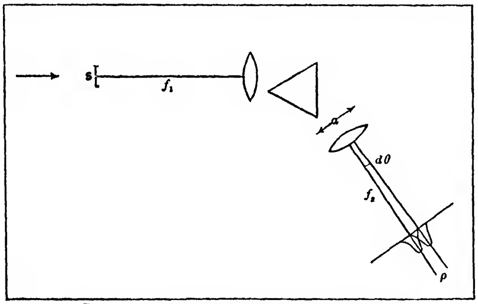

FIG 13 —RESOLVING POWER OF SPECTROGRAPH

$$R=(t_2-t_1)\cdot d\mu/d\lambda$$

When there are several prisms, the algebraical sum is to be taken as in the case of dispersion. A prism of ordinary flint glass of about 1 cm. base is thus found to have a resolving power for sodium yellow light of about 1,000, while a prism of 10 cm. base would have a resolving power of 10,000.

Purity of Spectrum.—In practice, it is necessary to give the slit a finite breadth, and the actual separating power must accordingly always be less than the theoretical resolving power The actual separating power is called the *Purity* and is defined by $P=\lambda/\Delta\lambda$ where λ is the wave-length of the light in question and $\Delta\lambda$ the difference in wave-length of two lines which are just divided While R is constant for a given instrument under the same conditions, P refers to the actual separating power in the spectrum obtained from it with the particular slit width employed and with any modified position of the prism P and R are related by the formula

$$P=R\frac{\lambda}{\lambda+As/f_1},$$

where A is the breadth of the incident beam s the width of the slit and f the focal length of the collimating lens

DIFFRACTION GRATINGS

Types of Gratings.—The diffraction grating is of great importance to the spectroscopist as providing him with the means of producing spectra of great dispersion and purity The first gratings were made by Fraunhofer about 1820, by winding thin wire over two fine screws of equal pitch kept an inch or two apart by bars of metal, the wires were soldered to the screws, and the whole framework was sawn in two along the axes of the screws, so as to make two gratings With these wire gratings Fraunhofer was able to measure the wave-length of sodium light with considerable accuracy

Modern gratings are made by ruling equidistant parallel lines with a diamond point on a plate of glass or speculum metal Those in most general use have about 15,000 lines per inch, but good gratings with 30,000 lines per inch have been ruled and may sometimes be used with advantage Among the most successful in the production of gratings was H A Rowland, of Baltimore, many of whose gratings are still in use and are highly prized Excellent gratings have also been ruled by R W Wood with Rowland's engine, by Prof A Michelson, of Chicago, and at the British National Physical Laboratory. The well known "Thorp gratings" are celluloid replicas of Rowland gratings and find extensive uses in physical laboratories

Gratings ruled on glass are called "transmission gratings" In these, the rulings act in the same way as the wires in Fraunhofer's gratings Most gratings, however, are ruled on speculum metal and are called "reflection gratings", speculum metal is chosen because it has the valuable property of reflecting light of all wave-lengths, so that the ordinary grating can be used for ultra-violet and infra-red as well as for visible spectra. Transmission gratings may also be used, but less effectively, as reflection gratings

Elementary Theory.—The production of spectra by a grating may be best explained by the consideration of a transmission grating, consisting of alternate opaque and perfectly transparent spaces, as coarsely illustrated in fig 14 A parallel beam of light of a single wave-length from a slit and collimator, with the slit parallel to the rulings, is supposed to fall at normal incidence on the grating Some of the light will pass directly through the grating in the direction of incidence and may be brought to a focus as an image of the slit—called the central image—by a suitable lens Each clear space, however, may be considered to be divided up into an indefinitely large number of small "elements," each of which may be supposed to act as a source of light, giving rise to cylindrical wavelets Some of the light is, therefore, found in other directions besides that of the incident light To investigate what happens in the direction AP, inclined at an angle θ to the incident light, let CB be drawn from the edge of an aperture C in the direction at right angles to AP, which is drawn from the edge of the adjacent aperture A If now θ be such that AB be just the length of one wave, the light coming from A in the direction AP will differ in phase by one whole wave from that proceeding from C, and the two will reinforce each other The first, second, and succeeding elements of the first aperture will thus be respectively reinforced by the corresponding elements of the second aperture, so that the waves from the whole of the two apertures will reinforce each other in the direction AP Similarly for other pairs of consecutive apertures across the whole grating, so that the light proceeding in the direction AP may be focussed

as a second image of the slit in light corresponding in colour to that of the incident light. A similar image will obviously be formed at the same distance on the other side of the normal. Other images of the slit will also be formed in directions at larger angles to the normal, such that AB is equal to other integral mul-

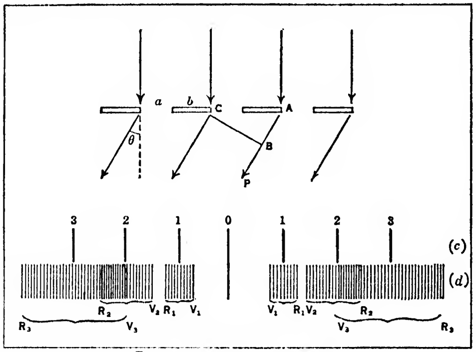

FIG. 14.—THEORY OF GRADING

tiples of the wave-length. The appearances with monochromatic light will accordingly be as roughly indicated in fig. 14c.

If the breadth of an aperture be a and that of a bar b, $(a+b)$ is called the grating space, and the directions in which the various images of the slit appear are defined by the condition

$$(a+b)\sin\theta = m\lambda$$

where $m=0, 1, 2 \ldots$ The central image is represented by $m=0$, while $m=1, 2 \ldots$ correspond to spectra of the first, second and higher orders. The complete theory, in agreement with observation, shows that in directions other than those in which AB is an integral number of wave-lengths the luminosity is negligible if the number of apertures is large.

The explanation of dispersion by a grating readily follows, since the formula shows that the angle θ increases or decreases with the wave-length. When composite light falls on the grating, it is clear that the shorter violet waves will give an image closer to the central image than the longer red waves. Thus, with white light, the appearances will be as roughly represented in fig. 14d. The dispersion increases and the intensity decreases with the order of the spectrum. The spectra of the different orders show a certain amount of overlapping, since $m\lambda$ may be given the same value in different ways. For example, λ7,000 in the first order will be coincident with λ3,500 in the second order; and λ4,000 in the third order would coincide with λ6,000 in the second. The overlapping of spectra impart complicates the use of a grating, but in practice one or the other can usually be cut out by a colour filter.

When the light does not fall normally on the wire grating, but is inclined at an angle i to the normal, it is readily found that the condition for the production of a spectrum line of wave-length λ is given by

$$(a+b)(\sin i \pm \sin\theta) = m\lambda.$$

It should be noted that when $i=\theta$ the grating is at the position of minimum deviation, the deviation then being $(i+\theta)$. The condition for coincidences in different orders of the spectrum, as before, is $m\lambda = m'\lambda'$ where m and m' are integers. It will be observed also that the determination of wave-lengths by the use of a grating merely requires a knowledge of the grating space, and the measurement of angles.

The Reflection Grating.—As for the transmission grating, the angles of incidence and diffraction are connected with the wave-length of the line observed by the relation:

$$\pm m\lambda = (a+b)(\sin i + \sin\theta),$$

where i and θ are each counted + or—according as they are measured in the conventional positive or negative direction from the normal to the grating, and m is similarly counted + or—with reference to the directly reflected light, for which $m=0$. In using this formula for calculation, it is usually convenient to express the grating space in angstrom units. Thus, in a grating having 14,438 lines per inch (most frequently occurring in Rowland gratings), there are 5,684 lines per centimetre, and since an angstrom unit is 10^{-8} cm. $(a+b)$ is 17,600 angstrom units. The formula shows, for example, that at normal incidence ($i=0°$), the greatest possible wave-length observable in the first order (corresponding with $\theta=90°$) is 17,600A; also represented by 8,800A in the second order, 5,866 in the third order, and so on. Greater wave-lengths, however, can be observed by changing the angle of incidence; thus, if $i=30°$ ($\sin i=0{\cdot}5$), the limiting wave-length ($\theta=-90°$, $\sin\theta=-1$) will be 35,200A in the first order ($m=-1$), 7,040A in the fifth order ($m=-5$), and so on.

Dispersion.—If θ be the angle of diffraction, dispersion is defined as before by $d\theta/d\lambda$, and since for a given position of the grating, the angle of incidence (i) is constant, the grating formula at once gives

$$d\theta/d\lambda = m/(a+b)\cos\theta.$$

The equation shows quite clearly how the dispersion varies directly with the order of the spectrum, and inversely as the grating space; the closer the rulings the greater the dispersion, irrespective of the total number. Again, it will be observed that the dispersion is smallest when $\theta=0$, ($\cos\theta=1$); *i.e.*, when the spectrum is observed in a direction normal to the plane of the grating. In this position also the dispersion is most nearly uniform throughout the whole spectrum, since it varies with $\cos\theta$, and in the neighbourhood of $\theta=0$ this changes very slowly. The spectrum given by a grating, unlike that given by a prism, is accordingly "normal" in so far as $\cos\theta$ can be considered constant.

Resolving Power.—As in the case of the prism, the resolving power of a grating is a theoretical quantity expressing the separating power when the slit is indefinitely narrow, and is represented symbolically by $R=\lambda/d\lambda$. It is given in a simple form by:

$$R = mN$$

or, the resolving power is equal to the product of the order number of the spectrum and the total number of rulings. It should be remembered, however, that N in this formula involves the aperture and grating space.

If a grating has 15,000 lines per inch and a ruled surface extending over two inches, the resolving power will be 60,000 in the second order. Thus, at λ6,000 the theoretical separating power would be 0·1A, while at λ3,000 it would be 0·05A. The resolving power increases towards the shorter wave-lengths because the diffraction bands become narrower.

The Concave Grating.—A very important contribution to the appliances for exact spectroscopy was made by Rowland in the introduction of concave gratings. These are ruled on concave speculum mirrors, which are generally of spherical form, but sometimes paraboloidal, and the rulings are intersections of equidistant parallel planes with the surface. The collimator and observing telescope are in this way dispensed with, because the ruled surface diffracts the rays from the slit to a focus. The instrument is equally good for the whole range of spectrum, since speculum metal is a good reflector for all wave-lengths and there are no lenses to produce absorption.

As with plane gratings, if i be the angle of incidence and θ that of diffraction, the formation of spectra involves the condition

$$\pm m\lambda = (a+b)(\sin i + \sin\theta)$$

and, to take the most general case, if ρ be the radius of curvature, R the distance from the slit to the centre of the grating, and r the distance from there to the focus, it may be shown that

$$r = \frac{\rho R\cos^2\theta}{R(\cos i+\cos\theta)-\rho\cos^2 i}$$

$$R = \frac{\rho r\cos^2 i}{r(\cos i+\cos\theta)-\rho\cos^2\theta}$$

Thus, if the slit be anywhere on a curve defined by the polar co-ordinates R and i, the spectra will be focussed on the conjugate curve defined by r and θ.

An important special case is that in which $R=\rho\cos i$, for then $r=\rho\cos\theta$ and the two curves coalesce in a circle of diameter ρ. This is often called the Rowland circle, and (fig 15a) if such a circle be drawn with the line joining the centre of the grating with the centre of curvature as diameter, and the slit S be at any point on this circle, the spectra of various orders will be focussed on the circumference of the circle. In Rowland's beautiful method of mounting, the slit is placed directly above the point of intersection of two firmly supported rails GS and SF, at right angles to each other, while the grating, G, is supported on a girder GF equal in length to the radius of curvature. The ends of the girder rest on little carriages which run on the rails, and since G, S and F always lie on the Rowland circle, different parts of the spectrum are focussed at F as the girder is moved from one position to another. With this construction, $\theta=0$ and $\therefore$ $m\lambda=(a+b)\sin i$; that is, the wave-length focussed at F is proportional to SF. In other words, as observed with an eyepiece and cross-threads the spectrum is truly normal, and the rail SF may be graduated directly on a uniform scale of wave-length. When a photographic plate is substituted for the eyepiece, it is placed in a holder that will bend it to the curvature of the Rowland circle, so that the whole of the spectrum is in focus. The spectrum is then only normal in so far as $\cos\theta$ can be considered equal to unity, because θ is only zero for the centre of the plate.

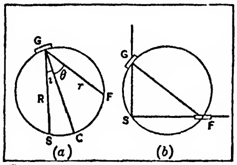

FIG. 15—(A) MAGNIFYING POWER OF GRATING, (B) THE CONCAVE

Rowland's largest gratings have a radius of 21 ft. and a ruled surface 6 in. wide, the rulings being about 2 in. in length. These give a first order visible spectrum about 5 ft long.

On account of the oblique incidence of the light falling on the grating, there is a considerable amount of astigmatism, so that even a point slit gives lines of considerable length, especially in the higher orders.

Numerous other constructions for concave grating spectrographs have been devised.

The Eagle mounting utilizes the spectrum seen in the direction of incidence, being essentially a Littrow spectrograph with a concave grating in place of a prism and lens; to bring different parts of the spectra under observation, the grating can be rotated and moved towards or from the plate, and the plate holder can be tilted to fit the Rowland circle. This mounting greatly reduces the astigmatism as compared with Rowland's arrangement, and therefore gives brighter spectra, and has the advantage that it can be enclosed in a rectangular box; higher orders of spectra can also be photographed.

When a collimator is used, so that parallel light falls on a concave grating, there is no astigmatism, and the spectrum is consequently brighter. In this form, slit, grating and plate are no longer on the Rowland circle and good focus can only be obtained over a moderate range of spectrum. The linear dispersion is reduced to about one-half of that given by Rowland's arrangement.

The Echelon Grating.—Since the resolving power of a grating is proportional to the product (mN) of the order of the spectrum and the total number of rulings, it may be increased in either of two ways. The first is to increase the number of rulings, but a limit is set to this by the practical difficulty of maintaining the rulings at a constant distance apart. The alternative method, which cannot be carried far with gratings of ordinary construction, is to use higher orders of spectrum. This, however, is very effectively done by a form of grating called the *echelon,* which was devised by Michelson in order to throw most of the light into one or two spectra of very high order. A number of glass plates of equal thickness (usually about a centimeter) and equal breadth, but each shorter than its predecessor by an equal amount (which may be about a millimeter) are superposed on each other to form a series of steps, like a staircase. Parallel light from a collimator, with the slit parallel to the edges of the steps, is then passed through the larger end. At each step the light is retarded by an equal amount, and diffraction spectra are produced when the light is focussed by a lens in the usual way.

Echelon gratings have been very successfully produced by Adam Hilger, Ltd., London, and an example given by this firm will illustrate the possibilities of such gratings. If the number of plates be 21, thickness, 10 mm, and height of step, 1 mm, while the refractive index for $\lambda 5{,}890$ is 1 5746, the instrument should be capable of separating lines about this wave-length which differ by only 0·027 angstrom units; in other words, the resolving power would be 218,000, and the order of spectrum observed would be the 10,380th. The successive orders are very close together, and on this account the light from the source is first passed through a spectroscope so that an image of the spectrum is focussed on the slit of the echelon instrument; only a very small range of wave-lengths then passes through. The lines are usually observed in the direction of the incident light, and under these conditions practically all the light is concentrated in a single order.

The echelon is clearly not intended for ordinary spectroscopic observations, but it is very valuable for analysing the fine structure of individual lines, small displacements of lines produced by pressure or other change of experimental conditions, and for revealing the close components into which a line may be split under the influence of a strong magnetic field. (*See* ZEEMAN EFFECT.)

Other High-Resolution Instruments.—Other instruments in which the effect of a large path-difference is used to produce high resolution are the Fabry-Perot interferometer and the Lummer-Gehrcke parallel-sided glass or quartz plate. (*See* LIGHT.) In each of these instruments, light from the original source is divided into a number of component beams of comparable intensity, which re-unite after having traversed paths differing successively by equal distances of perhaps a few centimetres. Reinforcement, giving a bright line or fringe, will take place when the effective path difference of neighbouring beams is an integral multiple of the wave-length, and it is readily seen that large path differences correspond to high resolution. For consider two neighbouring wave-lengths, λ and $\lambda+d\lambda$. The path difference, e, corresponding to m waves of the one will be equal to $m\lambda$, and that corresponding to m waves of the other will be $m(\lambda+d\lambda)$. The difference between these two quantities—*i e*, the interval between the positions of reinforcement for the two waves—will thus be $md\lambda=e\,d\lambda/\lambda=e/R$, where R is the resolving power. If, therefore, this interval be regarded as constant, at the value which just allows the wave-lengths to be distinguished, it is clear that R increases proportionately to e.

Absolute Measurement of Wave-length.—An instrument such as the Fabry-Perot interferometer, in which large and adjustable path differences are employed, provides a means of obtaining accurate measurements of wave-length, or, alternatively, of measuring the standard metre in terms of a given wave-length of light. For, from the equation $e=m\lambda$ already given, it is clear that if m can be measured we have the ratio e/λ and if e be equal to the standard metre we have the ratio between it and the wave-length of the light used. This experiment was carried out with great accuracy, first by Michelson and later, in a somewhat modified manner, by Fabry and Perot. The general method is described in the article INTERFEROMETER.

2. ANALYSIS OF SPECTRA

THE HYDROGEN SPECTRUM

The Balmer Series.—As a general rule the spectrum of an element presents no obvious regularity of structure. It appears to be a miscellaneous collection of lines with no element of order in their positions or intensities. The spectrum of hydrogen, however, furnishes a conspicuous exception to this rule. In the visible and near ultra-violet regions, this spectrum consists entirely of a regular succession of lines which occur at continuously dimin-

ishing intervals as the shorter wave-lengths are approached, and at the same time show a steady falling off of intensity. (Plate I., No. 6.) Such a succession is known as a *series* of lines. It should be remarked that hydrogen has two distinct spectra, produced under different conditions of excitation. Under weak stimulus it yields a "blue" open band spectrum with no evidence of simple structure; a stronger stimulus, however, produces a much simpler "red" spectrum. It is the latter which contains the series here referred to.

The regularity of the hydrogen spectrum led in the early days of spectroscopy to many attempts to interpret the lines as analogous to the fundamental and harmonic vibrations in acoustics. They failed because the wave-lengths or frequencies of the lines were not in the ordinary harmonic ratios and could be expressed by no formula in any way consistent with such an interpretation. It was not until 1885, in fact, that any reasonably accurate formula was suggested. In that year Balmer pointed out that the wave-lengths of the four lines of the series then known were accurately represented by the expression:

$$\lambda_m = 3645 \cdot 6(1 - 4/m^2)$$

if m were given the respective integral values, 3, 4, 5 and 6. All doubt as to the significance of this relationship was removed by the fact that several further prominent lines, photographed by Sir William Huggins in the ultra-violet spectra of the stars, were found to be represented by the same formula when the value of m was increased successively by steps of unity. The series has consequently come to be known as the Balmer series of hydrogen.

It is of advantage in theoretical discussions to express results in frequency, or wave-number, instead of wave-length. In these terms, if ν_m represents the wave-number of a line of the series, the Balmer formula becomes—adopting later and more accurate measurements:—

$$\nu_m = 27419 \cdot 67 - 109678 \cdot 3/m^2$$

or

$$\nu_m = R/2^2 - R/m^2$$

where $R = 109678 \cdot 3$.

One or two important conclusions at once follow from this formula. In the first place, the strong red line at $\nu 15233 \cdot 22$ ($\lambda 6562 \cdot 793$), corresponding to $m = 3$, is actually the first line of the series, for if $m = 0$, 1, 2, we obtain infinite, negative, and zero values for the wave-numbers, and these can have no physical significance. Secondly, no line of the series can occur further in the ultra-violet than $\nu 27419 \cdot 67$ ($\lambda 3645 \cdot 982$), corresponding to $m =$ infinity. The series is therefore wholly contained between the limits of wave-length, 6562·793 and 3645·982.

Other Series of Hydrogen.—The Balmer series is not, however, the complete "red" spectrum of hydrogen. In the extreme ultra-violet a similar series has been found (the Lyman series), and in the infra-red, yet another (the Ritz-Paschen series). The wave-numbers of the lines in these series respectively obey the equally simple formulae—

$$\nu_m = R/1^2 - R/m^2; \ (m = 2, 3, \cdots)$$

$$\nu_m = R/3^2 - R/m^2; \ (m = 4, 5, \cdots).$$

The natural deduction that a series, $\nu_m = R/4^2 - R/m^2$ might exist has been confirmed by F. S. Brackett, who has observed the first lines of such a series in the far infra-red. The difficulties of observation in this region are such as to prohibit the detection of further series of the same form.

It appears, therefore, that the wave-number of any line in the hydrogen spectrum can be expressed as the difference of two quantities. In any one series the larger of these quantities is constant, and represents the wave-number of the line of shortest wave-length that the series can theoretically contain. It is known as the *limit* of the series. The other quantity varies from line to line, and is known as the *term*. Clearly there is no fundamental difference between a limit and a term, for the limit of the Balmer series is a term of the Lyman series; the limit of the Ritz-Paschen series is a term of both the Balmer and the Lyman series; and so on. We can, therefore, generalize our results by saying that the hydrogen spectrum is associated with a number of terms of the form R/m^2 where m is any integer, and that the difference between any two of these terms corresponds to a possible line in the spectrum. The classification of the lines into separate series is thus somewhat arbitrary, and owes more to the visible appearance of the spectrum than to ultimate distinctions. In considering the nature of the spectrum, attention must naturally be concentrated on the terms, the lines being regarded as rather complex, derivative expressions of these simple fundamental quantities. From this point of view we may say that the whole of the hydrogen spectrum is expressed by the symbol R/m^2, where m ranges from one to infinity.

SPECTRA OF OTHER ELEMENTS

Series Formulae.—Evidence that series more or less resembling those of hydrogen occur in the spectra of other elements came from the pioneer investigations of J. R. Rydberg, H. Kayser and C. Runge. The spectra of the alkali metals (lithium, sodium, potassium, etc.) in particular can be almost completely analysed into series having the same general characteristics of convergence to limiting wave-numbers and continuous decrease of intensity, as the hydrogen series. (*See* Plate I., Nos. 8, 9, 2b.) A similar structure has been found in many other spectra also. None of these series, however (with one or two important exceptions which will be described later) can be represented by formulae quite so simple or so exact as those for hydrogen, although very close approximations can often be made. Rydberg's formula

$$\nu_m = A - R/(m+\mu)^2$$

(where A is the limit of the series; R—the "Rydberg constant"—has approximately the same value as for hydrogen; m takes successive integral values; and μ is a fraction, constant for each series) is sufficiently accurate for descriptive purposes, and will be so employed here, but more exact representation is given by the inclusion of an additional constant (α) as in the formula of W. M. Hicks—

$$\nu_m = A - R/(m+\mu+\alpha/m)^2.$$

Types of Series.—The series which were found intermingled in the various spectra were classified by Rydberg into types, characterised by the general appearance of the lines. Thus, in each of several spectra, a *principal*, a *diffuse* and a *sharp* series were found; a fourth series, the *fundamental*, was isolated later. The significance of these names has now almost disappeared, although the names themselves are still sometimes used, and the initial letters P, D, S, F are in general use to distinguish the different types of terms, and occasionally the series themselves. Other types of terms, which have been recognized only in recent times, are represented by the letters, G, H, . . . in alphabetical order, with no corresponding names.

The various series occurring in a spectrum are not independent of one another. Thus the S and D series converge to the same limit, and the difference between this and the limit of the P series is equal to the wave-number of the first P line. In other words, the first term of the P series is the common limit of the S and D series, and the first term of the S series is the limit of the P series. These reciprocal relations between the S and P series are known as the *Rydberg-Schuster law.* Again, the limit of the F series is the first term of the D series—a relation known as *Runge's law.* The four series are thus interconnected.

We may therefore express the various formulae, in the order in which they are now usually given, as follows:—

S series $\quad \nu_m = \dfrac{R}{(1+p)^2} - \dfrac{R}{(m+s)^2}$

P series $\quad \nu_m = \dfrac{R}{(1+s)^2} - \dfrac{R}{(m+p)^2}$

D series $\quad \nu_m = \dfrac{R}{(1+p)^2} - \dfrac{R}{(m+d)^2}$

F series $\quad \nu_m = \dfrac{R}{(1+d)^2} - \dfrac{R}{(m+f)^2}$

Here s, p, d, f, are the values of μ for the respective series, and it has been assumed, for simplicity of representation, that the value of m yielding the limit of each series is unity. For brevity the formulae are mostly written:—

$$\text{S series} \quad \nu_m = 1\text{P} - m\text{S}$$
$$\text{P series} \quad \nu_m = 1\text{S} - m\text{P}$$
$$\text{D series} \quad \nu_m = 1\text{P} - m\text{D}$$
$$\text{F series} \quad \nu_m = 1\text{D} - m\text{F}.$$

It appears, therefore, that, as with hydrogen, the consideration of the spectrum may be simplified by the substitution of terms for lines, the wave-number of each line taking part in a series being given by the difference of two terms. Instead, however, of a single sequence, R/m^2 of terms, there are in general four sequences—S, P, D, F—and possibly more. As before, there is no fundamental reason why the particular differences of terms constituting the prominent series should be differentiated from other differences of terms This was first realized by Ritz, whose well-known "combination principle" asserts that in addition to the series already described, a spectrum might contain lines represented by such expressions as $m_1\text{S}-m_2\text{P}$, $m_1\text{D}-m_2\text{F}$, etc. Many such lines have been observed There appears, however, to be a restriction on the possible combinations, which is expressed by what is called a *selection rule.* For the alkali spectra it may be stated as follows: If the sequences of terms be written in the order, S, P, D, F, G, H . . . , then a term of any sequence may combine only with a term of either of the neighbouring sequences Thus, any S term may combine with any P term, but not with another S term or with any term of the other sequences A P term, however, may combine with an S or a D term; and so on.

MULTIPLICITY OF TERMS

Systems of Terms.—For simplicity it has been assumed in the foregoing description that each member of a spectrum series consists of a single line This is sometimes the case, but more often the lines are double, triple, or even more complex. For example, in the spectra of the alkali metals the series consists of a succession of double lines, which in the spectra of the lighter elements are so close together as to appear single under small dispersion. (*See* Plate I, Nos. 8 and 9.) In zinc and certain other elements there are series of triplets The complications which this multiplicity introduces, though they were originally disentangled from observations of the lines themselves, can be best described by considering the terms, for the relations are there seen in their greatest simplicity.

It appears that terms may be classified in *systems,* known as singlets, doublets, triplets, etc , up to a limit which is theoretically indefinite but in practice rarely exceeds the multiplicity of octets. In a singlet system, all the terms, of whatever type, are single, like those considered in the last section In a doublet or triplet system, all the terms are double or triple except the S terms, which are single in each case In a quartet system, all the terms are quadruple except the S terms, which are single, and the P terms, which are triple These and other apparently irregular complexities are special examples of a general rule, viz —The multiplicity of a term is as large as possible subject to (a) never exceeding the multiplicity indicated by the name of the system to which it belongs; and (b) never exceeding 1 for an S term, 3 for a P term, 5 for a D term, 7 for an F term, etc. From this rule the multiplicities of the terms in any system can be at once written down.

Term Notation.—It is necessary now to elaborate the symbol representing a term so that it shall, first, indicate the system to which a term belongs, and secondly, in the case of a component of a multiple term, distinguish it from the other components. The system is indicated by an index at the top left hand corner, and the component number by a suffix on the right. For example, in a quartet system, the P terms are represented by $m^4\text{P}_1$, $m^4\text{P}_2$, $m^4\text{P}_3$. The particular figures used as suffixes are of no importance so far as the mere identification of terms is concerned, but for other reasons a definite scheme has been generally adopted, which is given in the following table for multiplicities up to 8.—

Inner Quantum Numbers (j)

Odd Multiplicities				
Terms	Singlet $r=1$	Triplet $r=3$	Quintet $r=5$	Septet $r=7$
S	0	1	2	3
P	1	0 1 2	1 2 3	2 3 4
D	2	1 2 3	0 1 2 3 4	1 2 3 4 5
F	3	2 3 4	1 2 3 4 5	0 1 2 3 4 5 6
G	4	3 4 5	2 3 4 5 6	1 2 3 4 5 6 7
Even Multiplicities				
Terms	Doublet $r=2$	Quartet $r=4$	Sextet $r=6$	Octet $r=8$
S	1	2	3	4
P	1 2	1 2 3	2 3 4	3 4 5
D	2 3	1 2 3 4	1 2 3 4 5	2 3 4 5 6
F	3 4	2 3 4 5	1 2 3 4 5 6	1 2 3 4 5 6 7
G	4 5	3 4 5 6	2 3 4 5 6 7	1 2 3 4 5 6 7 8

Selection Rules.—The reason for adopting these particular figures is that in combinations between multiple terms, another "selection rule" comes into operation, so that the combinations which are numerically possible do not all occur Consider, for example, a combination between a P and a D term in a quartet system The former is triple and the latter quadruple, and if each P component combined with each D component to give a spectrum line there would thus be 12 lines in all As a matter of fact, however, only 8 appear, and by choosing the suffix numbers according to the above table, these particular lines can be indicated by a very simple rule, viz —only those combinations occur for which the suffix numbers differ by zero or unity. Thus, writing the component terms as co-ordinates, and putting a cross at the position of each possible combination, we find the following group of eight lines as a typical quartet PD combination, or *multiplet,* as it is called —

	m^4D_1	m^4D_2	m^4D_3	m^4D_4
m^4P_1	×	×		
m^4P_2	×	×	×	
m^4P_3		×	×	×

Such a group of lines, it must be understood, is the analogue of a single line in a singlet system, and a succession of such groups in which the P component terms are the same and the D terms have consecutive values of m, constitutes a diffuse series in a quartet system.

It will be convenient at this stage to summarise and somewhat amplify the foregoing analysis, and at the same time to introduce a nomenclature derived from theoretical considerations which is in common use. A term is completely specified by four quantities —(1) Its *type*—S, P, D, etc This is sometimes represented by its *azimuthal quantum number*, and indicated by the letter k For an S term, $k=1$; for a P term, $k=2$, and so on. (2) Its *principal quantum number, n,* for which a serial number m is usually substituted in series formulae as above. (3) Its *system*—generally called the *multiplicity*, and denoted by the letter r. (4) Its *suffix number,* or *inner quantum number,* represented by j In expressing a term, the azimuthal quantum number is rarely used, the corresponding type symbol, S, P, D, etc , being retained instead thus, 4^3D_2 represents the second component of a D term in a triplet system for which the serial number is 4 A perfectly general representation of a term is $n^r k_j$.

When two terms combine to give a spectrum line they must satisfy the following conditions simultaneously —(1) The difference of the r values must be 0 or ± 2. This means that terms of different multiplicities may combine with one another, but the multiplicities must be both even or both odd (2) The difference of the k values must be ± 1. (3) The difference of the j values must be 0 or ± 1. There is one exception to the third rule; namely,

that if the j value is o for both terms, the combination does not occur. These three conditions do not involve the n values, which take no part in restricting the possible combinations of terms. It should be mentioned that there are also certain definite relations between the intensities of the lines in a particular combination of multiple terms, which are connected with the values of the inner quantum numbers. In theoretical discussions, intensities rank only second to wave-numbers, and much attention has been given to their exact measurement by Ornstein and others. The second and third selection rules are illustrated in fig. 16, which shows the structure of some of the doublet and triplet combination groups. The k rule, for example, forbids the combination SD, and the j rule reduces the number of lines in each group as compared with the number which is arithmetically possible, except in the SP group. The strongest lines of a group are those for which j changes in the same direction as k, and the intensity diminishes with the values of j which are involved.

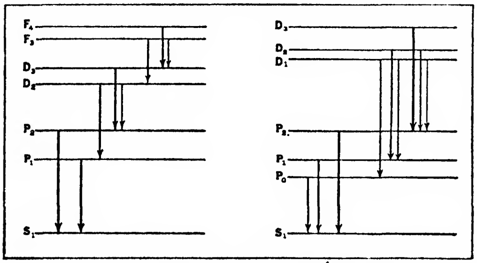

FIG. 16.—DOUBLET AND TRIPLET COMBINATIONS

A further complication must now be described. The terms of many spectra may be divided into two S, P, D, . . . groups, within each of which the combination rules just enunciated are obeyed. Combinations, however, may take place between terms of one group and those of the other. In such cases the rules are the same as before, with the exception of the one relating to the azimuthal quantum number, k, which becomes:—the difference of the k values must be o or ± 2. To distinguish the groups from one another, the term symbols for one of them are often followed by a dash at the top right hand corner; thus—S′, P′, etc. We may, therefore, have such combinations as PP′, DD′, SD′. . . but not SP′, PD′. . . . It is immaterial which of the groups is denoted by the dash, for there is, in fact, no difference between their properties except that indicated by the rules of combination.

Identification of Multiplets.—Well-developed series are usually found only in systems of low multiplicity, although the rule is not invariable. Singlet, doublet and triplet series have long been known, but it was not until 1922, through the work of Miguel A. Catalán, that the existence of systems of higher multiplicity was discovered. In spectra containing such systems it appears that the energy radiated is mainly distributed among the numerous lines of the earlier members of the series (*i.e.*, those corresponding to the smaller values of n), the later members being absent or relatively inconspicuous.

Although for descriptive purposes it has been thought desirable to deduce the structure of a complex spectrum from the multiplicity of its terms, the practical problem is, of course, the reverse; namely, to deduce and classify the terms from the regularities observed among the lines. In systems of low multiplicity, with well-developed series, this can often be done by careful inspection after some experience has been obtained, the numerical values of the terms being determined by the calculation of a Hicks or Ritz formula. With higher multiplicities, however, one looks for groups of lines belonging to particular combinations, such as the quartet PD combination referred to above. These are detected by the recurrence of certain wave-number differences between the lines in a group, and to a lesser extent by the relative intensities of the lines.

The true numerical values of the terms in these systems of high multiplicity cannot be determined unless sufficient members of a series are found to permit the calculation of a formula. Relatively accurate values, however, can always be found from the observations. Thus, in the above example, if the value of $^4S_2$ be known or assumed, all the other terms participating in the group can be at once evaluated by subtraction.

A good example of one of the many multiplets occurring in the arc spectrum of iron is illustrated in Plate I. No. 7, this representing the combination of a septet D and a septet F term, giving 15 lines.

Zeeman Effects.—The analysis of a spectrum is often facilitated by a study of the Zeeman effect, *i.e.*, the splitting of the lines into components when the source of light is placed in a strong magnetic field. (*See* ZEEMAN EFFECT.) The group, or pattern, into which each line is dissected depends, in general, on the quantum numbers, r, k, j, of its component terms, and, largely through the work of A. Landé, an algebraical expression involving r, k, j, has been found which in many spectra represents with extreme accuracy the number and relative separations of the components of a term. The pattern characteristic of each possible combination—*e.g.*, a $^3P_1$ $^1S_0$ combination—can thus be constructed, and by comparison with observation the lines can be classified. The pattern is not unique in every case—for example, all lines of a singlet system show the same pattern—but it is nevertheless a very valuable aid in analysis, and may be a crucial factor in deciding between alternative possibilities.

SPECTRA AND THE PERIODIC TABLE

General Relationships.—The spectra of a large number of elements have now been at least partially analysed, and it is possible to draw some general conclusions with regard to the relations between spectra and the periodic table. That some relations exist was indeed evident many years ago, when it was discovered that the spectra of elements in certain chemical families showed marked resemblances to one another. Thus the spectra of the alkali metals all show well-developed series of doublets; those of the alkaline earths show similar series of singlets and triplets, and so on. These now appear to be special cases of a general rule that elements of the same chemical family yield spectra with the same multiplicities. Furthermore, in progressing across the table from left to right, the multiplicities encountered are alternately even and odd, as may be seen by the following example taken from the third row of the table:—

Term Systems in Arc Spectra, K-Ni

Group	I.	II.	III.	IV.	V.	VI.	VII.	VIII.		
Element	19. K	20. Ca	21. Sc	22. Ti	23. V	24. Cr	25. Mn	26. Fe	27. Co	28. Ni
Multiplicities		1		1						1
	2		2		2				2	
		3		3		3		3		3
			4		4		4		4	
				5		5		5		5
					6		6		6	
						7		7		
							8			

The figures preceding the chemical symbols of the elements are the atomic numbers. Within a chemical family there is, in general, an increase in separation of component terms, roughly proportional to the squares of the atomic numbers, and at the same time a movement of corresponding lines towards the region of greater wave-lengths. It will be noticed that the low multiplicities occur mainly among the elements at the left of the table, and it was among these elements that series were first detected. The existence of complicated multiplets was first discovered by Catalán in the spectrum of manganese, which is derived from quartet, sextet and octet terms.

Enhanced Spectra.—It has already been mentioned that each element possesses a number of spectra, which are produced successively by gradually increasing the exciting stimulus. They are denoted, in the case of a typical element, Z, by the symbols, ZI, ZII, ZIII, etc. The type of structure which has been

described appertains to any of these spectra, but we meet with an important modification of the series formula in passing from one of them to the next, viz.—the value of the Rydberg constant, which is approximately $R = 109678$ for ZI, becomes approximately $4R$ for ZII, $9R$ for ZIII, and in general, n^2R for the nth spectrum. Since the other constants in the expression for the terms have the same general order of magnitude for all the spectra, it follows that the term values increase rapidly from one spectrum to the next.

There are strong reasons for believing that the number of such spectra which an element yields is equal to its atomic number. Thus, no increase of stimulus can produce a successor to the red spectrum of hydrogen (HI), or more than two spectra of helium, three spectra of lithium, etc. Owing to practical difficulties, it is only for the lightest two elements—hydrogen (H), and helium (He)—that lines of all the possible spectra have been observed, but the results in these cases illustrate a very important rule which from theoretical considerations, is believed to be quite general, namely: if n be the atomic number of an element, then its nth spectrum is as simple as the first spectrum of hydrogen, consisting only of terms of the form n^2R'/m^2, where R' is almost, but not quite, equal to R for hydrogen, and is very slightly different for each element. The lines of HeII were observed before this rule was known—first in the spectra of heavenly bodies and afterwards in the laboratory by A. Fowler—and, from the simplicity of the terms, were mistakenly attributed to hydrogen. It was not until the foundations of the theory of spectra were laid by Niels Bohr in 1913 that the true origin of the lines was indicated. Their connection with helium was afterwards confirmed by experiment.

Displacement Law.—There are certain significant relationships between the successive spectra of the same and neighbouring elements which must now be considered. Passing along the sequence, ZI, ZII . . . , we meet with an alternation of multiplicities similar to that already noted in the spectra of elements forming a row of the periodic table. The resemblance is not accidental, but is implied in what is known as the *displacement law* of A. Kossel and A. Sommerfeld, which in its generalized form states that the spectrum ZII will have the same multiplicity and general character as the first spectrum, YI, of the element preceding Z in the table; and further, that ZIII will resemble YII and XI—the first spectrum of the element preceding Y; and so on. The correspondence between these similar spectra is very close as regards multiplicities and the types of the most prominent terms, but it does not extend to the numerical values of the terms, which increase rapidly with the stimulus required to produce the spectrum.

As a particular example, consider the successive elements—sodium (Na), magnesium (Mg), aluminium (Al) and silicon (Si), details of which have been investigated by A. Fowler and F. Paschen. Here the spectra, NaI, MgII, AlIII and SiIV are strik-

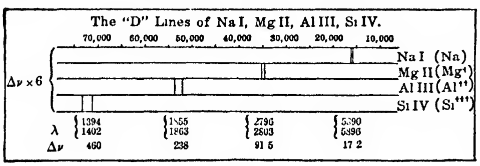

FIG. 17

ingly similar to one another, and may profitably be compared with the sequence of spectra of the alkali metals, NaI, KI, RbI, CsI. These two sequences have the spectrum NaI in common. They both consist of doublets, the separations between the components of which increase rapidly with advancing position in the sequence. But whereas, in the spectra of the alkali metals, corresponding lines move towards the red with increasing atomic number, the drift in the other sequence is towards the violet. Moreover, both the increase in separation of component terms, and the changes of position in the spectrum, are more regular in the NaI, MgII . . . sequence, as may readily be seen from fig. 17, in which the $3^2S–3^2P$ doublets are shown on a scale of wave-number. It appears as though the atomic systems which are responsible for the spectra NaI, MgII, etc., are more regularly related to one another than the atoms of elements of the same chemical family.

3. THEORY OF SPECTRA

THE HYDROGEN SPECTRUM

The Nucleus Atom.—From the earliest days of spectroscopy the question of the origin of spectra has engaged the attention of theoretical physicists, but it was not until 1913 that the line of investigation which has since proved so fruitful was inaugurated by Bohr. The earlier work can be summed up very briefly. The fact that a spectrum was characteristic of the emitting substance showed that it was an atomic or molecular phenomenon, and a theory of spectra therefore involved at least a partial theory of atomic and molecular structure The fact that both sound and light were conceived as trains of waves naturally suggested that the latter, like the former, might originate in periodic vibrations of material bodies, and the atoms of luminous substances were consequently looked upon as vibrating systems. But in those days there was no evidence of structure in the atom, and the character of the vibrations could be little more than guessed at Furthermore, as already stated, the frequencies of the radiations in even the simplest known spectrum—that of hydrogen—bore no relation to one another which could be reconciled with the harmonic ratios known in acoustics. It is not surprising, therefore, that no progress was made.

But by the year 1913 the developments of general physics had created a much more favourable situation for the solution of the problem. In the first place, a definite model of the atom, proposed by Sir Ernest Rutherford, was available, which consisted of a central nucleus positively charged with electricity, surrounded by a number of revolving electrons whose total (negative) charge balanced the charge of the nucleus One element differed from another in the nuclear charge, and consequently in the number of revolving electrons, this number being equal to the atomic number of the element. Thus, hydrogen had one revolving electron, helium, two, and so on. Secondly, other physical phenomena seemed to point to the conclusion that atoms could radiate energy only in definite unit quantities, known as *quanta,* the amount of which depended on the frequency of the radiation and was, in fact, equal to the product of the frequency and a constant quantity, h (Planck's constant). The application of this idea to the Rutherford atomic model enabled Bohr to give a quantitative explanation of the hydrogen spectrum and lay the foundations of the whole modern theory of spectra.

Bohr's Theory.—The physical conceptions of the Bohr theory will be described here only in so far as is necessary to interpret the facts of spectroscopy Their wider aspects are dealt with elsewhere. (*See* ATOM, QUANTUM THEORY) In order to explain the hydrogen spectrum, Bohr assumed that the single electron of hydrogen could revolve round the nucleus according to the ordinary mechanical laws, but only in any one of a series of discrete orbits, determined by the condition that the angular momentum must be an integral multiple of $h/2\pi$. The atom was, therefore, capable of existing in a number of states, known as *stationary states,* corresponding to the different possible orbits of the electron. The energy of the atom depended on the orbit of the electron, and was regarded as proportional to a term of the spectrum, each orbit thus being associated with a particular spectrum term. In the ordinary, non-radiating state of the gas, the electrons were in their innermost orbits, where their energy was less than that required for revolution in any other orbit, but on being stimulated to radiate, the atoms absorbed energy from the exciting source in just the amounts necessary to remove the electrons to outer orbits. An atom so excited, however, returned to its normal state at the earliest opportunity, either by a single jump or by successive transitions to intermediate permissible orbits. At each transition it radiated the difference of energy corresponding to revolution in the two orbits concerned

as a spectrum line of frequency ν, where $h\nu$ was the energy radiated. An inward passage between each pair of orbits thus resulted in the radiation of a particular line in the spectrum, whose wave-number was equal to the difference of the corresponding terms, and the whole spectrum consisted of the sum of the radiations of all the atoms in the radiating source.

Treating these conceptions mathematically, Bohr was able to deduce the Balmer and other formulae for the hydrogen series, and further, to show that the Rydberg constant, R, was given by

$$R=\frac{2\pi^2 e^2 E^2}{ch^3}\cdot\frac{mM}{m+M}$$

where e, m are respectively the charge and mass of an electron, E, M, are the corresponding quantities for the nucleus, and c is the velocity of light. For hydrogen, with only one electron, $e=E$, but M is nearly 2,000 times m. The spectroscopic determination of R, in fact, now appears to be one of the most accurate methods of determining the ratio of M to m, and gives a value, 1,845.

OTHER SPECTRA

The Series Constant.—The mathematical difficulties of a complete solution of the motion of electrons in atoms with more than one electron have proved insuperable, but a physical idea of the process of radiation by such atoms can be formed. It is supposed, as a first approximation, that passages from orbit to orbit are performed mainly by a single electron, the others meanwhile revolving unchanged in their normal orbits. In such a case, if the dimensions of the orbits of the roving electron are large compared with the dimensions of the rest of the atom (the *core*, as it is called), the latter may be regarded as a single positive charge, E (equal and opposite to the charge, e, of an electron), round which the roving electron moves. The calculation made for hydrogen is then approximately applicable, and gives a formula in which the Rydberg constant, R, recurs. The deviation from exactitude results in the change of m (the denominator in the expression for the hydrogen terms) from an integer to a mixed number. Its new value—$(m+\mu)$ in the Rydberg formula—is known as the *effective quantum number*.

Ionised Atoms.—The universal occurrence of the constant R is thus explained, and a natural extension of the theory provides a simple explanation of the fact that for the successive spectra of each element, it must be multiplied by 2^2, 3^2, etc. For, consider an atom subjected to a gradually increasing stimulus. Its travelling electron will be able to move out to more and more distant orbits until a point is reached when it absorbs enough energy to leave the atom altogether. The atom is then said to be *ionised*. The remainder of the atom, being still subjected to the exciting stimulus, will be able to absorb energy only by the removal of a second electron to outer orbits, and the new transitions of this electron will generate a spectrum different from that given by the un-ionised atom. For in this case the positive charge, E, of the core is 2e—*i.e.*, twice the charge of an electron—and the expression for R becomes $4\cdot\frac{2\pi^2 e^4}{ch^3}\cdot\frac{mM}{m+M}$ —approximately four times the value of R for hydrogen. In a similar way, a still greater stimulus will remove a second electron from the atom, which is then said to be doubly ionised, and the spectrum generated by the movements of a third electron will give a spectrum involving a constant approximately $9R$, and so on.

It should be observed that the values of the constant for the corresponding spectra of different elements are not exactly the same because of the factor $Mm/(M+m)$. Here M is the mass of the core, which is practically equal to the atomic weight of the element, and it is easily seen that the variation of M brings about a slight, but only a slight, variation of $Mm/(M+m)$. The effect of this variation, however, is of some importance in the case of atomic systems containing only one electron. Thus, the line $R/2^2-R/3^2$ of the Balmer series, of hydrogen, for example, would clearly be identical in position with the line $4R'/4^2-4R'/6^2$ of HeII if R were exactly equal to R'. Actually, however, the lines are separated by about 2½A. It was on account of this and similar separations, predicted by the Bohr theory, that it was first realized that the lines of HeII were not due to hydrogen.

Absorption.—The explanation of absorption on the Bohr theory is fairly obvious. If emission corresponds to an inward transition of an electron, absorption will naturally correspond to an outward transition. Since the energy values of the orbits are constant, it follows that the frequencies absorbed will be the same as those capable of being emitted, and the relation between the absorption and emission spectra of an element is thus explained. It is clear, however, that absorption by a non-luminous vapour should on this view produce only the lines in which the innermost orbit (or the largest spectrum term) is involved, for in the initial state, all the atoms will have their travelling electrons in this orbit. This agrees with observation, as for example in the case of potassium vapour (Plate I., B. 2) which, when not radiating, absorbs only the principal series, 1S–mP. The innermost orbit corresponds to the term 1S, which, as we have seen, can under the selection rule combine only with P terms.

In ordinary absorption the electron is ejected outwards by light of the proper frequency in the incident beam. A similar ejection can be brought about by electron bombardment, as in the experiments of Franck and Hertz and others. (*See* art., RESONANCE POTENTIAL.) In these and similar experiments the energy is usually imparted to the bombarding electron by an electric field, and the potential difference through which the electron has to fall to acquire sufficient energy to excite the atom from its normal state to the next possible state is known as the *resonance potential* of the atom (*q.v.*). Similarly, the potential difference necessary to enable the bombarding electron to ionise the atom is known as the *ionisation potential* of the atom. Clearly the ionisation potential is a measure of the energy of the atom in its normal state, and is, therefore, proportional to the largest term in the spectrum. It is given in volts by dividing the largest term, expressed in wave-number units, by 8,102.

Interpretation of Terms.—In applying the ideas of the Bohr theory to the facts concerning the spectra of the elements already described, the outstanding problem is to interpret the four numbers which specify a spectroscopic term, namely, $n^r k_j$. The conception that each of these numbers may be identified with a definite characteristic of an electron orbit is clearly incomplete, inasmuch as the movements of a point charge, such as an electron is conceived to be, can be completely defined by three quantities, whereas observation shows that four are to be accounted for. This difficulty has been partly overcome by assuming that an electron can rotate about an axis, thus giving it an additional "degree of freedom," but the more advanced developments of the theory seem to indicate that even this amplification is insufficient to interpret all the facts of observation, and the whole conception of electron orbits may have to be regarded as merely a symbolical one. For that reason the phrase "energy of an orbit" is often discarded in favour of the more general one, "energy level of the atom." The simple conception of spinning electrons in orbital motion, however, gives a fairly clear picture of what is happening when a spectrum is emitted.

In the earlier days of the theory, it was supposed that the spectrum was generated by the transitions of a single electron between different orbits, and that the k value of a term (1 for S, 2 for P . . .) was always simply related to the corresponding orbit; so that, for example, if the term were 3P the orbit was considered to be specified by 3_2. The principal quantum number n was then regarded as an index of the major axis of the orbit (supposed in the general case to be an ellipse), and k was considered to represent the minor axis, n_k thus indicating the size and shape of the orbit associated with a particular term. The interpretation of r and j, however, remained somewhat vague and incomplete. An important indication of the need for further development of the theory was also subsequently given by the analysis of the more complex spectra, it being then found that the term representing the normal state of an atom was sometimes of a type which was very unlikely to represent the orbit of the most loosely bound electron in the unexcited atom.

In identifying the quantum numbers of the terms with the elements of a single electron orbit, it is implied that when an

atom is excited, only a single electron is disturbed; but it is obviously conceivable that the exciting agency might disturb two or more electrons simultaneously, with the result that the energy level of the atom might be altered in a way inexpressible in terms of the movements of a single electron. Evidence that this actually occurs was first brought to light by Henry Norris Russell and F. A. Saunders in a study of the spectrum of calcium. They showed in effect that terms existed in the spectrum larger than the term corresponding to the ionisation potential of the element. This meant that the atom contained more than enough energy to ionise it if all the energy were given to one electron, and it naturally followed, since the atom was not ionised, that the energy was shared between two or more electrons.

A more general problem than that so far considered was thus opened up. A spectrum term could no longer be regarded as necessarily characterized by the elements of a single orbit; it had to be conceived as measuring, in the most general case, the sum of the energies of all the electrons in the atom, each of which might be changed when the atom was excited to a new state. Fortunately it appears that, with the ordinary methods of exciting spectra at least, only a few of the electrons are disturbed, and remarkable progress has been made in correlating the distribution of electron orbits with the spectrum terms It is now possible to state what terms correspond to any given configuration of electrons, and so to predict the possible terms in the spectrum of an element when the probable orbits of its electrons are known

Two distinct problems are involved First, the specification of the orbits of all the electrons in an atom in the normal state and in the states which are most probable when the atom is excited. Secondly, the determination of the spectroscopic terms corresponding to these various states. The former problem has been solved mainly through the labours of Bohr, Main Smith and Stoner; the results so far as the normal state are concerned will be found elsewhere. (*See* ATOM, MAGNETISM, QUANTUM THEORY) The same results for the arrangement of electrons in the normal atoms of the elements also follow from Pauli's exclusion principle, which asserts that not more than one electron can have the same four quantum numbers which are now necessary to define its motions completely Thus, proceeding outwards from the nucleus, the so-called K shell, or group, cannot contain more than two electrons, the L shell eight, and so on. In excited states the outermost, or valence, electrons are most easily disturbed and experience has shown that their movements usually account for the most prominent terms occurring in spectra.

The solution of the second problem is largely due to the work of Heisenberg and Hund, the whole theory being based on the supposition that the angular momenta of all the rotary motions within the atom can only be changed by unit steps. These rotary motions, for each individual electron, require four quantum numbers for their complete specification. Besides n and k, which determine the size and shape of the orbit, there are also two so-called "magnetic quantum numbers," one of them involving the orientation of the orbit and the other the direction of spin, each electron being assigned half a unit of angular momentum. The problem of predicting the spectroscopic terms for different arrangements of the electrons is, fortunately, greatly simplified by the fact that electrons which are in completely filled n_k groups can be disregarded, as it follows from Pauli's principle that the resultant angular momentum for such groups is zero. The general outcome of the extended theory is that the quantum numbers which define the spectroscopic terms are now to be regarded as resultants of those which define the characteristics of the outer or valence electrons. The process by which the terms are deduced from the atomic states, however, is too complex to be described here, and, in fact can scarcely be indicated completely in terms of the orbital model of the atom

The theoretical prediction of the spectroscopic terms to be expected for given configurations of the electrons, however, has already been of immense service in the disentanglement of many complicated spectra, and there is every reason to believe that the elucidation of the structures of all line spectra, and their correlation with atomic structures, is not far distant.

SPECTROSCOPY, X-RAY. It is now a generally accepted fact that X-rays form a branch of ordinary optics Proceeding from the visible light (8,000–4,000 Ångstrom units) to the electromagnetic waves of shorter wave-lengths we are able by recent spectroscopic methods to pass without any break through the ultra-violet region (the Schuman-Lyman-Millikan regions) to the realm of wave-lengths characterizing X-rays (extending from some hundredths to about one tenth of an Ångstrom unit). On the short wave-length side of the X-ray region we pass into those wave-lengths known as the radioactive gamma-radiation and the still shorter wave-lengths of the "cosmic" rays.

Historical Remarks.—That the X-rays produced in an ordinary X-ray tube are complex and differ in quality when the vacuum of the tube, or primarily the tension on the tube, is varied was noted by Rontgen himself in his first papers dealing with the new radiation It was shown early that the X-radiations became more penetrative as the tension of the tube was raised The degree of penetration (usually measured in terms of the thickness of aluminium necessary to reduce their intensity by half) was used as a means of characterizing the quality of the radiation

It was by this means also that C G Barkla was able to show that the different elements when excited so as to give off X-rays all have their own "characteristic" radiations For instance for an element such as silver Barkla showed the existence of two "characteristic" radiations called the K- and L-radiation having very different penetrating power

The K-radiation from this element is reduced to half its intensity after passing through a sheet of aluminium about 1 mm thick whereas the L-radiation is diminished in the same degree only after it has passed through 0 004 mm of aluminium.

These two characteristic radiations, the K-series and the L-series, were experimentally verified for a great number of elements. The measurements of their penetration in aluminium showed that their "hardness" increases regularly for both series when the atomic weight of the emitting element increases

Corresponding to the emission of the characteristic fluorescent radiation of a certain element, Barkla and his collaborators, especially Sadler, showed the existence of a remarkable abnormality in the absorption of the X-rays. This was the first indication of what is now called the absorption-spectra in the field of X-rays, and which have been shown to be intimately connected with the emission spectra or characteristic radiation of the elements

Basis of the X-ray Spectroscopy.—The knowledge which had so far been obtained regarding the characteristic X-radiation

and absorption was extended to quite a new branch of spectroscopy after the fundamental discovery of Laue (1912). By this discovery experimental science obtained the tool that was necessary for exploring the fascinating subject, which X-ray spectra of the elements turned out to be.

The diffraction patterns which Friedrich and Knipping obtained on allowing a fine beam of X-rays to pass through a crystal as

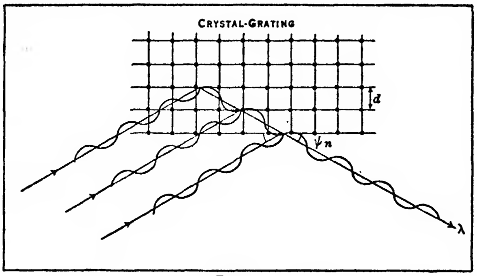

FIG. 1

suggested by Laue induced W. H. and W. L. Bragg to perform experiments, which formed the first step of the development of the X-ray spectroscopy. As the Braggs showed, a monochromatic X-ray beam is reflected by a cleavage face (or any other atomic plane) of a crystal according to the ordinary laws of optical reflection, *i.e.*, the incident and the reflected beams are in the same plane and this plane is perpendicular to the reflecting face, and further the angles between these two beams and the reflecting face are equal. In addition to these laws the following condition must be fulfilled if reflection is to occur, namely:

$$n\lambda = 2d\sin\phi \qquad (1)$$

where λ is the wave-length of the monochromatic radiation, d is the distance between two adjacent atomic layers parallel to the reflecting plane, ϕ the angle between the beam and the plane and n indicates the "order" of the reflection. (Fig. 1.)

This equation, generally known as *Bragg's law,* forms the basis for measuring the wave-lengths of X-rays. It may be mentioned that this law needs a small correction, due to the fact that the wave-length is slightly different in a vacuum (or air) and in the crystal.

Spectrometric Methods.—The arrangement for the spectroscopic analysis of an X-ray beam is shown diagrammatically in

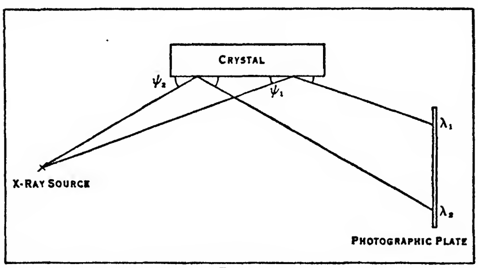

FIG. 2

fig. 2. The different monochromatic rays which constitute the beam coming from the X-ray source (or slit) are reflected by the crystal at different angles and directions according to the Bragg law (1) as the angles may vary from ϕ_1 to ϕ_2 only such rays are reflected whose wave-lengths have values between λ_1 and λ_2 where

$$n\lambda_1 = 2d\sin\phi_1$$
$$n\lambda_2 = 2d\sin\phi_2.$$

On the photographic plate therefore there is found, after exposure and developing, a spectrum ranging from λ_1 to λ_2. The region of wave-lengths of course can be varied by turning the crystal.

From the position of a certain spectral-line on the photographic plate its wave-length is computed by equation (1). A number of different methods have been used for determining the angle ϕ which forms the main problem of the X-ray spectrometry.

Exciting of X-ray Spectra.—To excite the X-ray spectrum of a substance a small piece of it is placed on the anticathode (3a, 3b) of an X-ray tube. After the tube has been exhausted to a suitable vacuum a high potential (10 to 150 kilovolts) is applied to the electrodes of the tube. By this means the anticathode is bombarded by the electrons forming the cathode rays. The kinetic energy of the electrons imparted to the bombarded atoms is partially transformed into heat, light, etc., and partially to X-rays. We will here deal exclusively with the last mentioned rays and more especially with the question as to how this radiation varies with the material on the anticathode.

As to the X-ray tube and its working there are two main ways of producing the cathode rays used for bombardment. In the first

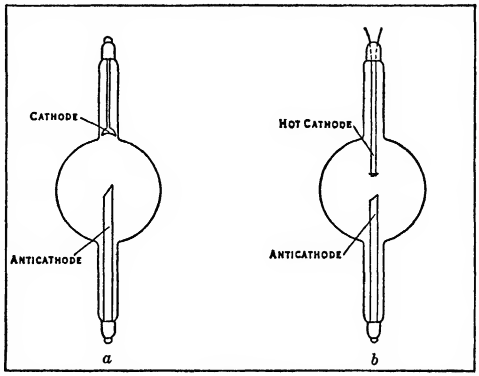

FIG. 3

type (3a) the tube has a vacuum of 0·01 to 0·001 mm. Hg. The high-potential in this case is the indirect cause of the ionization of gas remaining in the tube and the positive ions formed are thrown against the cathode (of aluminium) and on their collision set free a number of electrons. The electrons travel in the opposite direction—from the cathode to the anticathode—and bombardment of the anticathode gives rise to X-rays characteristic of the substance of the anticathode. In the second type (3b Coolidge-tube) the vacuum of the tube is much lower, so that no current passes through the tube when the high-potential is applied to the tube. In this case the electrons for the cathode rays are supplied by heating to a high temperature a filament (mostly of tungsten) which is placed in the centre of the cathode.

For analysing purposes it is often necessary to change the substance on the anticathode and the tube must be built in such a way that the anticathode is easily detachable. This can be accomplished by mounting the anticathode in a special joint. A tube especially designed for spectroscopic purposes which permits rapid change of both cathode and anticathode is shown in fig. 4. The tube itself is built of metal with water cooling to permit a very high output of energy. Further a small window of aluminium or goldbeater's skin makes it possible to study the radiation of longer wave-lengths which are absorbed by the glass walls of an ordinary tube.

Another way of exciting X-ray spectra is to irradiate the substance with an intense beam of X-rays. In this case the substance emits "secondary" rays which, with a few exceptions, are identical with the X-radiation sent out by the same substance used as an anticathode in an X-ray tube. This method does not however give the same intensity as the former.

Different Kinds of X-ray-spectra.—The X-ray spectrum emitted from an arbitrary substance is built up of two kinds of radiation one of which shows a continuous distribution over a wide range of wave-lengths, the other consisting of a few mono-chromatic rays overlapping the former. The first mentioned radiation corresponds to the "white" light of ordinary optics, whereas the second is analogous to the line-spectra. The continuous spec-

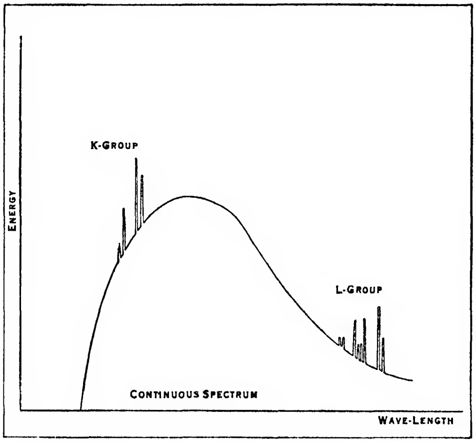

Fig. 4

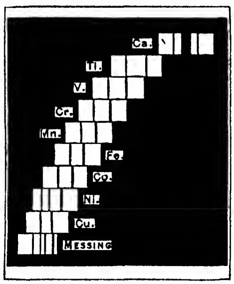
trum contains the greater part of the energy of radiation and is therefore the most important part for medical and many other applications of the X-rays. This part of the X-ray spectrum shows qualitatively no dependence of the radiating substance, the intensity only being different from various anticathodes.

The line-spectra on the other hand are characteristic of the emitting substance. They correspond to the K- and L-radiation of Barkla, but analysis has shown that each of these radiations consists of a group of mono-chromatic spectral-lines.

If the energy of the radiation is plotted in a diagram as the function of the wave-length a curve (fig. 5) is obtained.

In addition to the emission-spectrum of X-rays there is also an absorption-spectrum analogous to the absorption spectra of ordinary optics Such spectra are obtained when a sheet of thin foil of some substance is placed between the X-ray source and the photographic plate Instead of a continuous blackening from the white X-radiation the plate shows one or more sharp edges where there is a rapid change in the blackening, these edges are called "absorption-edges" The wave-lengths of these absorption-edges show an intimate relation to the characteristic line-spectrum of the substance used as absorbing screen. Such absorption-spectra were first obtained by Duc Maurice de Broglie and given right interpretation by Sir William Bragg and M. Siegbahn. Fig. 6 is a reproduction of a spectral-plate showing these three kinds of spectra.



FROM SIEGBAHN, "SPEKTROSKOPIE DER RÖNTGENSTRAHLEN" (SPRINGER)

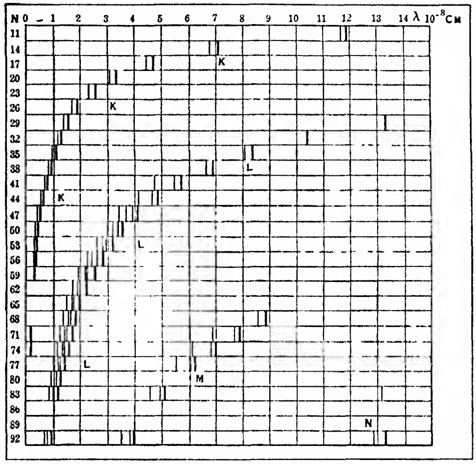
FIG 5.—MESSING BRASS

The Continuous Spectrum.—As already mentioned the "white" or continuous radiation from an X-ray tube covers a rather wide region of wave-lengths. The diagrams of fig. 7 give an idea of the distribution of the energy of the different wave-lengths at voltages from 20 to 50 kilovolts. The curves of distribution always start at a definite minimum wave-length (λ_{min}). The value of this wave-length decreases with increasing voltage

It has been found empirically and verified by many investigators that this wave-length (λ_{min}) or its corresponding frequency $\left(\nu_{max} = \frac{1}{\lambda_{min}}\right)$ obeys the Einstein law

$$\nu_{max} = \frac{eV}{h} \qquad (2)$$

where e is the charge of the electron, V the tension on the tube,



FROM SIEGBAHN, "SPEKTROSKOPIE DER RONTGENSTRAHLEN" (SPRINGER)

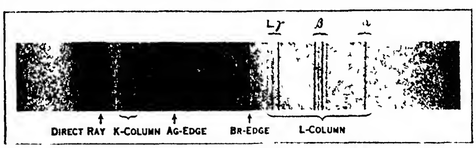
FIG 6—DIAGRAM SHOWING THE STRONGEST LINES OF THE SEVERAL X-RAY SERIES FOR EVERY THIRD ELEMENT

and h = Planck's constant If the numerical figures of e and h are introduced the equation may be written

$$\lambda_{min} = \frac{12.3}{V} \qquad (3)$$

where the wave-length is expressed in Å.U (10^{-8} cm.) and V in kilovolts.

The physical interpretation of the equation (2 3) is given by the quantum theory as follows When the potential is applied between the cathode and the anti-cathode an electron on passing from the former to the latter acquires the energy. eV If the electron is suddenly brought to rest at the anticathode this



FROM SIEGBAHN, "SPEKTROSKOPIE DER RONTGENSTRAHLEN (SPRINGER)

FIG 7—SPECTRUM FROM A COOLIDGE TUBE WITH TUNGSTEN ANTI-CATHODE

energy is given off as an electromagnetic wave with the frequency ν and containing the energy ν, which gives

$$h\nu = eV$$

which corresponds to the above equation (2) for the maximum frequency Generally the electron before being completely stopped will suffer several collisions and will send out smaller amounts of energy or waves of smaller frequencies

The *total amount of energy*, that is, the integral energy included by the distribution-curves in fig 7, has also been measured by many investigators As the result of these researches it can

be stated that *the total energy is proportional to the square of the voltage on the tube.*

Secondly it has been found (by G. W. C. Kaye and others) that for different elements used as anticathode the *total radiation is proportional to the atomic number of the element.*

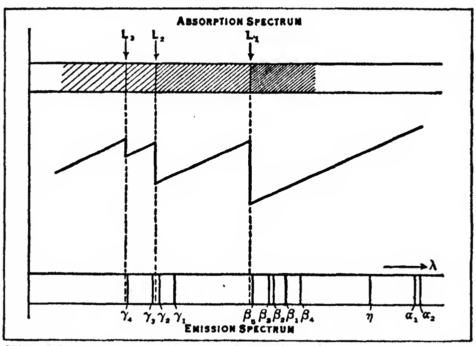
Already in the early days of X-ray technique it was found advantageous to use heavy elements as anticathodic materials for the medical X-ray tubes, an observation which is in agreement with the last general law.

The Line-spectra.—In 1913 and 1914 the young English physicist H. G. J. Moseley published two very remarkable papers in the Philosophical Magazine entitled *"The High-frequency spectra of the elements."* The two papers contain the first announcement of the birth of a new branch of optics. Moseley showed in these publications that there existed in the realm of X-rays line-spectra of the same type as was known in ordinary optics and at the same time that these new spectra were built up in a much more simple and regular way than is generally the case in the spectra which had previously been studied.

Two groups of spectral-lines were found. One of these groups was identified with the K-series of Barkla; the other, of longer wave-length and of more complex structure, corresponds to the L-series. The fig. 8 is a reproduction from Moseley's paper of spectra of successive elements from Ca (atomic number 20) to Zn (30). It shows in the most beautiful way how regularly the spectra—in this case the K-group—repeat themselves from one element to the next. With increasing atomic number (here from 20 to 30) of the emitting element the line-group is displaced in regular steps towards the shorter wave-length. This rule is not confined only to these elements and this group, but is universally confirmed by all X-ray spectra.

In 1916 M. Siegbahn discovered a new series of still greater wave-lengths called the M-series. The existence of series outside the K- and L-group had already been suspected earlier by reasons of analogy. In the later development of X-ray spectroscopy some indications of still other series, N, O, etc., have been traced, but further experimental work is necessary before more reliable statements can be made.

A general scheme of the X-ray spectra is given in the diagram fig. 9 which contains the strongest lines of the three groups K, L and M at every third element from Na (11) to U (92). The



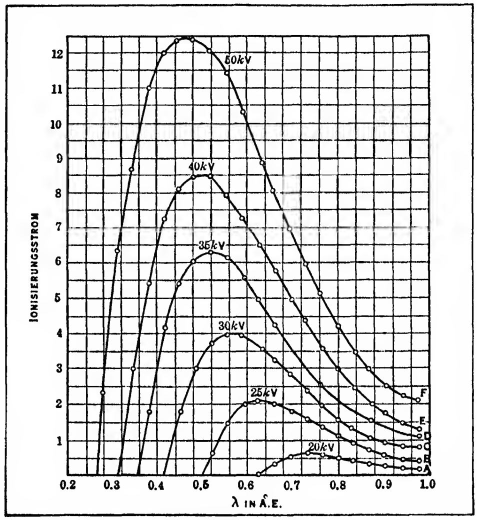
FROM SIEGBAHN, "SPEKTROSKOPIE DER RONTGENSTRAHLEN" (SPRINGER)

FIG. 8.—DIAGRAM OF THE ABSORPTION AND THE EMISSION SPECTRUM SHOWING THE RELATIVE POSITIONS OF DISCONTINUITIES AND LINES

diagram shows how all three series are regularly displaced to longer wave-lengths as one proceeds from the heavier elements to the lighter. If the spectrum of some special element, say Tungsten, a material commonly used for the anticathode, is considered it will be seen that there are big gaps between the three groups where no lines are to be found. This fact is of predominant importance in interpreting the spectra in their relation to the structure of the atom.

As to the structure of the different groups it may be mentioned that the K-group generally consists of 4 lines ($\alpha_1\alpha_2\beta_1\beta_2$) the L-group of more than 20 lines (the strongest lines designed by $\alpha_1\alpha_2$, $\beta_1\beta_2\beta_3\cdots$, $\gamma_1\gamma_2\cdots$) and finally the M-group of about 20 lines.

Most of the X-ray spectra consists of a very easily absorbed radiation so that in using an ordinary X-ray tube they will not reach outside the glass-walls. In the diagram in fig. 9, only



FROM SIEGBAHN, "SPEKTROSKOPIE DER RONTGENSTRAHLEN" (SPRINGER)

FIG. 9.—INTENSITY DISTRIBUTION OF THE CONTINUOUS RADIATION FROM A TUNGSTEN ANTICATHODE AT VARIOUS VOLTAGES

the small portion between the vertical lines 0 and 1 Å.U. includes the radiation given off by the technical X-ray tube. Hence for the study of X-ray spectra, one is confined to the use of tubes with thin foils as windows and spectrometers built for vacuum.

The Absorption Spectra.—As already mentioned the absorption spectra, obtained by putting a screen of the substance between the X-ray source and the spectral plate, usually have the appearance of a sudden, sharp drop in the blackening of the plate. The wave-lengths of these absorption-edges may be determined with a fairly high accuracy though not with the same precision as the lines of the emission-spectra.

The study of these spectra have shown that there is always *one* absorption-edge in the region of wave-lengths where the K-group of the same element is located. In the region of the L-group there are *three* absorption-edges and finally in the domain of the M-group experiments have revealed *five* edges.

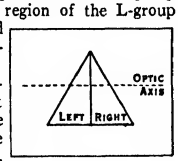


FIG. 10

As to the K-absorption-edges the measurements of their wave-lengths show that they have, if not exactly, very nearly, the same values as those of the line with the shortest wave-lengths within the K-group.

How the three absorption-edges of the L-group are located relative to the L-emission-lines is shown in figure 8. As seen from this diagram here also the edge with the shortest wave-length agrees with the shortest emission-line. It is reasonable to suppose that the L-group may be divided in three sub-groups of lines of which every one is related to one of the three edges as is the case in the K-group. A numerical analysis of the material strongly supports this view as will be stated later.

Analogous results concerning the five edges within the M-group indicate the existence of five sub-groups in this series.

It may be added that in some cases especially at long wave-lengths and with light elements the absorption-edges are under certain experimental conditions replaced by white lines situated at the same place as the edges Also more complex structure of white lines with darker fields have been registered in these cases.

Connection Between Emission- and Absorption-spectra.—As soon as reliable measurements of the two kinds of X-ray spectra, line- and absorption-spectra, had been performed it was immediately clear that there existed a very intimate relation between them If the frequencies of the absorption-edges are indicated by

K for the one absorption-edge within the K-group
L_I L_{II} L_{III} for the three absorption-edges within the L-group
M_I M_{II} M_{III} M_{IV} M_V for the five absorption-edges within the M-group

it is found that the differences between some of these values give exactly the frequencies of some of the emission-lines. For instance the differences $K-L_{II}$ and $K-L_{III}$ give the values of the frequencies of the two strongest lines of the K-group namely $K\alpha_1$ and $K\alpha_2$. On calculating the difference between some of the above M-values and the K-value other lines belonging to the K-group are obtained

In the same way a difference between L_I, L_{II} and L_{III} with some of the values of the higher absorption-edges (M_I M_{II} $\cdots$) gives emission-lines of the L-group. Now these connections between the absorption and emission-spectra allow an extension which seems highly probable. The frequencies obtained by calculating the difference between the three L-values and the M-values include only part of the L-emission-lines, but supposing the existence of higher absorption-frequencies N_I N_{II} N_{III} $\cdots$ O_I $\cdots$ of suitable frequencies the remaining L-lines may be accounted for as differences between absorption-frequencies. The existence of these higher absorption edges has not as yet been directly experimentally proved but they are strongly supported by the fact that also lines of the M-group may be calculated from them in the same way as were the L-lines.

If this hypothesis is right we should expect that there are for the heaviest elements *seven* absorption-edges, *five* O and probably three P-edges.

Now it may be added that not all the numerical differences between two arbitrary absorption-values correspond to emission-lines. Somę of these "calculated" lines for some reason or other do not exist; they belong to what are called "forbidden" transitions

Physical Interpretation of the X-ray Line-spectra and the Structure of the Atom.—According to the Bohr-Rutherford hypothesis the atoms are built up of a positive nucleus of comparatively small dimensions which is surrounded by a number of electrons If this general picture of the atom is accepted the X-ray spectra furnishes us with a lot of valuable information regarding the feature of the electronic part of the atom. Then plausible calculations show that the X-ray series of highest frequencies, the K-series, must be ascribed to those electrons which form the innermost part of the electronic atmosphere of the atom. The higher series consequently correspond to successive electronic transitions outwards to the surface-layers of the atom, where we meet the region of the ordinary optical spectra.

In the X-ray absorption-spectra according to this view we find the different energy-levels pictured, which correspond to the energy-output necessary to remove one or other of the electrons of the atom. In consequence we speak of the K-level, the L-levels, etc. of the atom. Or if we wish to indicate the parts of the electronic atmosphere, the K-shell, the L-shell, etc , each of these shells may of course include more than one electron. For instance it is probable that the K-shell contains two electrons, the L-shells eight electrons, the M-shell eighteen electrons and so on.

After one electron has—by absorption of energy—been thrown out from its place within the atom its place will soon be filled up by an electron which through the attraction of the positive nucleus falls from some of the outer shells into the empty place. This means a diminishing of the energy of the atom, the superfluous energy being sent out as an X-ray wave In this way we understand the emission of, for instance, the K-line in the following manner One of the electrons belonging to the K-shell has by absorption of energy been removed, its place is taken up by an electron from the L-shell, accompanied by emission of the K-α-line As after this process there is an empty place in the L-shell this may again be filled say by an M-electron with emission of an L-line and so on

It is immediately seen that this picture of the absorption and emission-process is in conformity with the connection between the two kinds of spectra discussed in the preceding paragraph.

As to the structure of the electronic shells of the atoms some general conclusion may be drawn from the empirical knowledge of the X-ray spectra, which, as just mentioned, may be interpreted as coming from the different layers of the electronic atmosphere of the atom.

First the fact that the X-ray spectra of all the elements show a very big resemblance to each other and change from element to element mainly by moving toward higher frequencies must mean that the general structure of the electronic layers within the atom is the same for all elements The increasing of the frequencies is readily understood by the increasing positive charge of the nucleus and the accompanying strengthening of the attractive forces acting on the electrons

Secondly the appearance of the distinct and widely separated groups. K, L, M . indicate that the electronic atmosphere of the atom consists of distinct layers or shells with decreasing energy-contents beginning with the innermost shell, the K-shell followed by the L-shell, the M-shell and so on

Thirdly all these shells or groups of electrons (except the K-group) are divided into sub-groups as indicated by the existence of more than one absorption-edge or energy-level within every main group.

Further information regarding the structure of the atom is obtained by considering the completeness or rather lack of completeness of the X-ray spectra of the different elements. If one starts with the heaviest element, uranium (with atomic number 92) and proceeds towards the lightest elements it is found that successively and systematically a number of spectral lines (and consequently also absorption-edges) vanishes That means the successive peeling off of electronic shells whereby the number of possible transitions between the groups are reduced The remaining lines and edges of every atom consequently show directly the number of layers and furnishing us with a means of mapping out the electronic structure of the different elements. If we confine ourselves to the inert gases the empirical study of the X-ray spectra suggests the existence of the following shells filled with a number of electrons as given in the table on p. 200.

X-ray Spectra and Chemical Constitution.—The most striking difference between the ordinary optical spectra and the X-ray spectra is the fact that the former show a marked resemblance between elements with same chemical character and change considerably from one group of chemically analogous elements to another whereas in the X-ray spectra no indication of the chemical nature of the elements is to be found This is readily understood by the picture of the atom and its relation to the spectra which has just been given From this interpretation the optical spectra arise from the surface of the atom which is also the seat of the chemical bounds, while the X-ray spectra are given off from the inner parts of the electronic atmosphere of the atom. But of course it is to be expected that a small influence may be seen if an atom emitting an X-ray is acted upon by neighbouring atoms This is a question of the sensitivity or accuracy in the methods of studying the X-ray spectra. By increasing the precision of the measurements it has been possible to detect a number of such effects as just mentioned; for instance it has been shown by Bergenren and Lindh that the K-absorption-edges are a little displaced when the atom (Phosphorus, Sulphur and Chlorine especially have been studied) enters in different chemical combinations. The valency of the atom seems to be one of the main factors in this respect so that by investigations of the kind valuable information regarding the valencies may be obtained

But the line-spectra are also in a certain degree influenced by the chemical bonds as shown by Lundquist, Bäcklin, Ray, etc.

Finally we may in this connection point out the service that the X-ray spectroscopy has rendered as a method of chemical analysis and for the detection of new elements. On the suggestion of Bohr that the element with atomic number 72 may be sought in minerals containing its homologue Zirkon, Coster and Hevesy succeeded in identifying this new element by its X-ray spectrum. Berg, Noddack and Tacke gave convincing evidence of the unknown elements 75 and 43 by X-ray methods. (M. Sie.)

SPEE, MAXIMILIAN, Count von (1861–1914), German sailor, was born in Copenhagen on June 22, 1861. He entered the German navy in 1878 and from 1887 to 1888 was Hafenkommandant (commander of the port) in German Cameroon. In 1908 he was made chief of staff of the German North sea command, and at the end of 1912 took over the Far Eastern Squadron. On Nov. 1, 1914, he was engaged by Admiral Cradock off Coronel, on the Chilean coast, and succeeded in defeating the British squadron. On Dec. 8, 1914, however, he was attacked by Admiral Sturdee's cruiser squadron. The Germans were heavily defeated in the battle that took place. This is usually known as the battle of the Falkland islands, and in it Spee himself went down with his flagship, the "Scharnhorst." (*See* Coronel; Falkland Islands.)

SPEED, JOHN (1552–1629), English historian and cartographer, was the son of a London tailor, and followed his father's trade, being admitted member of the Merchant Taylors Company in 1580. He settled in Moorfields, where he built himself a house. He was enabled to devote himself to antiquarian pursuits through the kindness of Sir Fulke Greville, whom Speed calls the "procurer of my present estate," and through his patron's interest he also received a "waiter's room in the custom-house." His important works are: *Theatre of the Empire of Great Britaine* (1611), a series of fifty-four maps (with descriptive matter) of different parts of England, which had already appeared separately, and in which he was helped by Christopher Saxton, John Norden and William White; and *History of Great Britaine under the Conquests of the Romans . . . to . . . King James* (1611). Speed brought some historical skill to bear on the arrangement of his history; in preparing it he received help from Sir Robert Cotton, William Smith, Henry Barkham and Sir Henry Spelman. Speed brought some historical skill to bear on the arrangement of his work, and although he repeated many of the errors of older chroniclers he added on the whole a substantial contribution of valuable material for the history of his country. He died in London on July 28, 1629.

Other maps of his, beside those in the *Theatre,* are in the British Museum. Another edition of the *Theatre* is *Theatrum Magnae Britanniae latine,* redditum a P. Holland (London, folio, 1616). He wrote *Genealogies Recorded in Sacred Scriptures* (1611), and a similar work, *A Cloud of Witnesses* (1616). These passed through numerous editions, and were frequently prefixed to copies of the Bible. An account of Speed's descendants is to be found in Rev. J. S. Davies's *History of Southampton* (1883), which was founded on ms. material left by John Speed (1703–1781).

SPEEDOMETERS, instruments for measuring linear speeds—more particularly the speeds of road vehicles—and graduated in miles (or kilometres) per hour. They are driven either from one of the road wheels, or from the transmission, through a flexible shaft and a gear mechanism. Account is taken of the diameter of the road wheel and of the gear ratio between the wheel and the speedometer shaft. Speedometers carry a so-called odometer, which indicates distance.

Main Principles.—The oldest speedometers depend on centrifugal force. A pair of weights is carried on a revolving shaft, in such a manner that they may move out from the axis as in the Watt conical pendulum governor, being restrained by a spring. The faster the shaft revolves, the farther the weights will move out from the axis of rotation. An indicator records the speed.

A second principle very extensively used is that of magnetic drag. A cup of sheet aluminium is mounted on a spindle and held in the "zero" position by a spiral spring. A permanent magnet whose lines of force pass through the wall of the cup is rotated inside the latter at a speed proportional to that to be measured. The rotation of the magnet induces currents in the aluminium cup and the reaction between these currents and the magnetism of the magnet produces a drag on the cup, which causes it to turn around its axis against the resistance of the spring, and in proportion to the speed of the magnet. A scale printed on the outside of the cup shows through an opening in the face of the instrument, and the scale reading in line with a mark on the face indicates the speed.

A third principle made use of is based on the fact that speed is the quotient of distance by time. Instruments based on this principle comprise an odometer and a clockwork, measuring distance and time respectively, and they effect the operation of division mechanically.

A further principle is that of the magneto and voltmeter. A magneto generator has the characteristic that the voltage generated by it varies with the speed at which its armature is driven. Therefore, if a magneto is placed in driving connection with a road wheel and its terminals are connected to a voltmeter whose scale, instead of in volts, is graduated in miles per hour, the combination will serve as a speedometer. This type is particularly adapted for use where it is desirable to take readings at a long distance from the road wheel as the only connection is by wires. (P. M. H.)

SPEEDWELL, in botany the name applied to the 17 British species of the genus *Veronica* (family *Scrophulariaceae*); the British forms are herbs with bright blue flowers. The genus *Veronica* contains about 250 species, temperate, alpine and arctic, many of which are shrubs or trees with handsome spikes of flowers, and are often cultivated The woody forms are especially characteristic of the mountains of New Zealand. Some 15 species occur in North America, including several that have been naturalized from the Old World. The culver-root (*Veronica virginica*), found across the continent, was formerly much used in medicine.

BY COURTESY OF THE WILD FLOWER PRESERVATION SOCIETY

THE COMMON SPEEDWELL (VERONICA OFFICINALIS), WHICH BEARS SMALL PINK, BLUE OR WHITE FLOWERS

SPEENHAMLAND SYSTEM, a system of poor relief adopted by the Berkshire magistrates in 1795, by which the wages of labourers were supplemented from the poor-rates up to a certain level, an additional dole being permitted for each child. At a critical moment the Berkshire justices were forced to adopt a desperate remedy, but it was a pernicious plan, for it unfairly transferred the burden of wages from the employer to the rate-payer, it encouraged the farmers to pay inadequate wages, and degraded the labourer to the position of a pauper. The system lasted until

the new Poor Law of 1834; it was never in force in Scotland or the north of England.

SPEKE, HUGH (1656–c. 1724), English writer and agitator, was a son of George Speke (d. 1690) of White Lackington, Somerset. Educated at St. John's College, Oxford, Hugh Speke joined the Green Ribbon Club, and in 1683 he was put in prison for asserting that Arthur Capell, earl of Essex, had been murdered by the friends of the duke of York In prison Speke kept a printing-press, and from this he issued the *Address to all the English Protestants in the Present Army,* a manifesto written by the Whig divine Samuel Johnson (1649–1703), urging the soldiers to mutiny. In 1687 he was released, and in 1688 he served James II as a spy in the camp of William of Orange. In December of this year a document, calling upon the Protestants to disarm their Roman Catholic neighbours was freely circulated, and much damage was done to property in London before it was found that it was a forgery. Speke asserted his authorship in his *Memoirs* (1709), revised as *The Secret History of the Happy Revolution in 1688* (1715). Speke died in obscurity before 1725.

SPEKE, JOHN HANNING (1827–1864), English explorer, discoverer of the source of the Nile, was born on May 4, 1827, at Jordans, Somersetshire He entered the Indian Army in 1844. He served under Sir Colin Campbell's division in the Punjab When on furlough Captain Speke explored the Himalayas, and crossed into Tibet In 1854 he joined Richard Burton in Somaliland, as narrated in *What led to the Discovery of the Source of the Nile* (London, 1864) In April 1854 Speke was wounded by Somalis. Invalided home, he volunteered for the Crimea and served with a regiment of Turks

In 1856 Speke joined Burton in exploration of the African lakes, especially Nyassa The route to Nyassa was closed by the Arabs, and the travellers left Zanzibar in June 1857 by a more northerly route They learnt from an Arab trader that further inland were three great lakes—and Speke assumed that the most northerly would be the source of the Nile. In January 1858 the travellers reached Lake Tanganyika By June they were back at Kazé, and here Speke induced his chief, who was ill, to allow him to attempt to reach the northern lake Marching north for 25 days, on July 30 Speke reached a creek, along which he travelled till, on Aug 3, he saw it open up into the waters of a lake extending northward to the horizon. He no longer doubted that this lake—the Victoria Nyanza—was the source of the Nile Returning to Kazé (Aug. 25) he made known his discovery to Burton, who did not believe Speke's theories

Speke had the support of Sir Roderick Murchison, president of the Royal Geographical Society, under whose direction a new expedition was fitted out. Of this expedition Speke had the command, his only European companion being Captain (afterwards Colonel) J. A Grant (*q v*). The expedition, over 200 men all told, started from Zanzibar in Oct. 1860 and reached Kazé on Jan. 24, 1861 The Victoria Nyanza was again reached, at its south-west corner, in Oct. 1861. Following the western shores of the lake Speke crossed the Kagera Jan 16, 1862, and arrived at the capital of Uganda on Feb 19 following. Here he was detained by the king Mtesa, for some months, but at last prevailed on the chief to furnish him with guides, and on July 28 Speke stood where the Nile issued from the lake The travellers were not permitted to visit another large lake (the Albert Nyanza) of whose existence and connection with the Nile they learned As far as possible Speke and Grant followed the course of the Nile, and on Dec. 3 came in touch with the outside world once more On Feb. 15, 1863, they arrived at Gondokoro At Gondokoro they met Sir Samuel (then Mr.) Baker, generously giving him the information which enabled him to discover the Albert Nyanza

In the same year (1863) Speke published his *Journal of the Discovery of the Source of the Nile,* a work written in a frank, attractive style. His conclusions were disputed by Burton and McQueen in *The Nile Basin* (1864), it being argued in this work that Tanganyika was the true Nile source. Speke was to discuss the question with Burton at the geographical section of the British Association at Bath on Sept. 16, but he accidentally shot himself while out after partridge on Sept. 15.

See, besides the works mentioned, Sir R. F. Burton, *The Lake Regions of Central Africa* (1860), J A. Grant, *A Walk across Africa* (1864), T D Murray and A S White, *Sir Samuel Baker: a Memoir* (1895), *The Times* (Sept. 17 and 19, 1864); Sir H. H. Johnston, *The Nile Quest* (n d. [1903]).

SPELL, a word of Teutonic origin meaning something "spoken." In general terms, the belief underlying the use of spells is that the wish that they embody will be fulfilled, regardless of its goodness or badness, so long as the formula has been correctly pronounced Broadly speaking, then, spell and prayer, like magic and religion to which they severally belong, can be distinguished by the nature of the intended purpose

Ritual is to be seen in relation to its moral context as a whole For instance, the judicial oath may have lost some of its special significance as a religious act of binding force, but, taken in connection with the solemn endeavour, of which it forms a part, to administer justice in the light of the truth, its validity can hardly be said to have been affected. Or, again, charges of formalism as regards the details of religious worship are recklessly bandied about, when the spirit and not the letter of the observance should alone be regarded as relevant to the issue Next, as regards the criterion of intelligibility, we must make sure in using it that we are not making our own ignorance the measure of the intrinsic value of the rite alleged to be without meaning Just as any foreign tongue is gibberish to the unlearned, so we may be deaf to the most eloquent symbolism if we have not a key to the sense

To take an example from Australia, if members of the witchetty grub totem desire to secure a harvest of these grubs for the benefit of the community, they repair in procession to certain stones that remind them by their shape of witchetty grubs and rub their stomachs with these stones, thus indicating the precise destination to which the symbolized delicacies are meant to find their way. Moreover, this pantomime is reinforced by oral means in the solemn declaration, "We have eaten much food"; where, let the perfect tense be noted, as if for the man of faith the thing were as good as done.

The chief deity of the Masai goes by the name that simply means "The Rain"; and the simplest of their rites consists in crying out "Rain! Rain!" in chorus (*see* PRAYER). Here the question whether this is prayer or spell ought not to turn on the degree of personality attaching to the god, and still less on a grammatical point such as the possible use of the imperative mood Surely the religious character of the whole proceeding is sufficiently established by the fact that "The Rain" is for the Masai, the reputed giver of all good things.

In primitive rite the verbal formula tends to be accessory to the dramatic part of the procedure Sometimes it is but descriptive of the action, "We are doing so and so," though sometimes the purpose is added, "We are doing so and so, that so and so may happen" Thus the efficacy of the rite, words and all, is apt to seem self-contained The rite has *mana* (*q v*), which is almost to say "It works, I know not why" in one pregnant word. Correspondingly, it becomes a perilous instrument for the ordinary man to handle, and its use is reserved for the man with *mana*—the expert who is strong enough to wrestle with mysteries Now to be vested with esoteric attributes in one's own eyes no less than in the eyes of the rest bears hard on the weakness of the flesh True, the wonder-worker may be ready to admit that his *mana* possesses him rather than he it An Australian medicine-man, for instance, who had given way to European strong drink, became convinced that his healing power had left him and in a spirit of befitting humility retired from practice Or, again, we have the Malay wizard whose spell explicitly announces that some power greater than himself is working through him "It is not I that am burying him (in the form of a waxen image), it is Gabriel who is burying him."

In Melanesia and elsewhere a man owns a ritual and charms so completely that he can bequeath them to a son Nay, he can even sell them in the open market, and in such a case we expressly learn that the oral part of the rite—the muttered spell—is what the money is paid for, since it is what the owner can most easily hide and so keep to himself. At this point the spell has clearly

become a non-moral thing, a mere trade secret. It will degenerate still further into *abracadabra*. The folklorist is constantly coming across oral survivals in the mouths of peasants that once were medical recipes or even prayers couched in Latin. Afterwards, when reduced to mere rigmarole, these have been treasured by the unlettered for the sake of the sheer mystery lurking in the unfamiliar sounds. (R. R. M.)

SPELLO (*Hispellum, q.v.*), a town of Umbria, 1,030 ft. above sea-level. Pop. (1921), 2,849 (town); 6,161 (commune). S. Maria Maggiore contains some of Pinturicchio's finest frescoes (1501), "The Annunciation," "The Adoration" and "Christ in the Temple."

SPELMAN, SIR HENRY (*c.* 1564–1641), English antiquary, was the eldest son of Henry Spelman, of Congham, Norfolk, and the grandson of Sir John Spelman (*c.* 1495–1544), judge of the king's bench. He was educated at Walsingham School, and Trinity college, Cambridge. With Sir Robert Cotton and William Camden, he belonged to the Society of Antiquaries, which declined, and Spelman's efforts to revive it in 1614 were frustrated by James I. A judgment given against him by Bacon in a case over the crown lease of two abbeys led to his pamphlet *De non temerandis ecclesiis* (1613–16), which induced many lay owners of ecclesiastical spoils to make restitution, and Spelman himself acted accordingly. Spelman proposed to write a work on the foundations of English law, based on early charters and records; as a preliminary to this task he began to compile a glossary, the first volume of which, *Archaeologus in modum glossarii*, was published at his own expense in 1626. He continued to work at the subject until 1638. A second volume, *Glossarium archaiologicum* (1664), appeared after his death. His *Codex legum veterum statutorum regni Angliae, quae ab ingressu Gulielmi I usque ad annum nonum Henry III. edita sunt* was published by David Wilkins in his *Leges anglo-saxonicae* (1721). Spelman's most important work, *Concilia, decreta, leges, constitutiones in re ecclesiarum orbis britannici* (2 vols., 1636–64), is an attempt to place English church history on a basis of genuine documents. Spelman entered parliament as member for Castle Rising in 1597, and took a prominent part in public business until his death (Oct. 1641). He was buried in Westminster Abbey.

Edmund Gibson, bishop of London, published in 1723 *The English Works of Sir Henry Spelman, Kt., Published in his Lifetime; together with his Posthumous works relating to the Laws and Antiquities of England*. The first section contained *De non Temerandis Ecclesiis*, already mentioned; *The Larger Treatise concerning Tythes*, first published in 1646; *De sepultura;* and *Villare anglicum, or a View, of the Towns of England;* while the second included *The Original Growth, Propagation and Condition of Feuds and Tenures by Knightservice in England*, written in 1639; *Two Discourses: i. Of the Ancient Government of England, ii. Of Parliaments; The Original of the Four Terms of the Year*, written in 1614 and first printed in 1684; *Icenia:* a Latin description of Norfolk, and some other treatises. This was a revised edition of an earlier collection (1698), and contained a life of the author, based chiefly on the autobiographical matter prefixed to the Glossary of 1626, and two additional papers, *Of the Admiral Jurisdiction, and the Officers thereof*, and *Of Antient Deeds and Charters*. Wilkin's edition of his *Concilia* was edited by A. W. Haddan and W. Stubbs in 1869–73.

SPENCE, THOMAS (1750–1814), inventor of a system of land nationalization, was born at Newcastle-on-Tyne on June 21, 1750, the son of a Scottish netmaker and shoemaker. He proposed the establishment of self-contained parochial communities, in which rent paid to the corporation, in which the absolute ownership of the land was vested, should be the only tax of any kind. His pamphlet, *The Meridian Sun of Liberty*, which was first hawked in Newcastle, appeared in London in 1793; it was reissued by Mr. H. M. Hyndman under the title *The Nationalization of the Land in 1775 and 1882*. Spence presently left Newcastle for London, where he kept a bookstall in High Holborn. In 1784 he spent six months in Newgate gaol for the publication of a pamphlet distasteful to the authorities, and in 1801 he was sentenced to twelve months' imprisonment for seditious libel in connection with his pamphlet entitled *The Restorer of Society to its Natural State*. He died in London on Sept. 8, 1814. His admirers formed a "Society of Spencean Philanthropists." (*See* Harriet Martineau's *England During the Thirty Years' Peace.*)

See also Davenport, *Life, Writings and Principles of Thomas Spence* (London, 1836); O. Rudkin, *Thomas Spence* (1926).

SPENCER, HERBERT (1820–1903), English philosopher, was born at Derby on April 27, 1820. His father, William George Spencer, was a schoolmaster, and his parents' religious convictions familiarized him with the doctrines of the Methodists and Quakers. He declined an offer from his uncle, the Rev. Thomas Spencer, to send him to Cambridge, and so was practically self-taught. During 1837–46 he was employed as an engineer on the London and Birmingham railway; in 1848–53 as sub-editor of the *Economist*. From about this time to 1860 he contributed numerous articles to the *Westminster Review*, which contain the first sketches of his philosophic doctrines. He also published two larger works, *Social Statics* in 1850, and *Principles of Psychology* in 1855. In 1860 he sent out the syllabus of his *Synthetic Philosophy* in ten volumes, which he completed in 1896 with the *Principles of Sociology*. He died on Dec. 8, 1903.

Spencer's significance in the history of English thought depends on his position as the philosopher of the great scientific movement of the second half of the 19th century, and on his friendship with men like Darwin, G. H. Lewes, and Huxley. He tries to express in a general formula the belief in progress which pervaded his age, and to erect it into the supreme law of the universe. But to the specialists in sciences which were advancing rapidly to results which often transformed their initial assumptions, Spencer has often appeared too much of a philosopher and defective in specialist knowledge; to the technical philosophers he has not seemed philosophic enough.

Spencer claims, with some reason, that he was always an evolutionist. But his notions of what "evolution" is developed gradually. At first he seems to have meant only the belief that progress is real, and that the existing order of nature is the result of a gradual process. In *Social Statics* (1850) he still regards the process teleologically, and argues after the fashion of Paley that "the greatest happiness is the purpose of creation" (ch. iii. § 1). In *The Development Hypothesis* (1852) he objects strongly to the incredibility of the special creation of the myriad forms of life, without, however, suggesting how development has been effected. In *Progress, its Law and Cause* (1857) he adopted Von Baer's law, that the development of the individual proceeds from the homogeneous to the heterogeneous. This is at once connected with the nebular hypothesis, and subsequently "deduced" from the ultimate law of the "persistence of force," and finally supplemented by a counter-process of dissolution, all of which appears to Spencer only as "the addition of Von Baer's law to a number of ideas that were in harmony with it." Spencer welcomed Darwin's *Origin of Species* (1859) and enriched its doctrines with the phrase "survival of the fittest"; but he did not give up the (Lamarckian) belief in the hereditary transmission of the modifications of organisms by the exercise of function.

Of his *First Principles* (1862) the first part shows that while ultimate metaphysical questions are insoluble they compel to a recognition of an inscrutable Power behind phenomena which is called the Unknowable; the second part is devoted to the formulation of the Law of Evolution. In the first part Spencer's argument rests on Mansel's *Limits of Religious Thought* and Hamilton's "philosophy of the conditioned" (and so ultimately on Kant), and tries to show that in scientific and religious thought the ultimate terms are "inconceivable" (not by him distinguished from "unimaginable"). In science, the more we know the more extensive "the contact with surrounding nescience." In religion the vital and constant element is the sense of mystery. This is illustrated by the difficulties inherent in the conception of Cause, Space, Time, Matter, Motion, the Infinite, and the Absolute, and by the "relativity of knowledge," which precludes knowledge of the Unknowable, since "all thinking is relationing." Yet of the Unknowable we may have an "indefinite knowledge," positive, though vague. Hence both science and religion must recognize as the "most certain of all facts that the Power which the Uni-

verse manifests to us is utterly inscrutable." In the edition of his *First Principles,* published in 1900, he adds a "postscript" which shows some consciousness of the contradiction involved in his knowledge of the Unknowable, and finally contends that his account of the Knowable in part ii. will stand even if part i. be rejected. But, in reality, a really inscrutable Unknowable would destroy all confidence in the order of nature and render all knowledge precarious.

In part ii. Spencer recognizes successively likenesses and unlikenesses among phenomena (the effects of the Unknowable), which are segregated into manifestations, vivid (object, non-ego) or faint (subject, ego), and then into space and time, matter and motion and force, of which the last is symbolized by our experience of resistance, and is that out of which our ideas of matter and motion are built Hence the Persistence of Force is the ultimate basis of knowledge From it Spencer deduces the indestructibility of matter and energy, the equivalence and transformation of forces, the necessity of a rhythm, of Evolution (*i e*, integration of matter with concomitant dissipation of motion) and Dissolution, and finally the statement of the Law of Evolution as "an integration of matter and concomitant dissipation of motion, during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity, and during which the retained motion undergoes a parallel transformation" This process of evolution is due to "the instability of the homogeneous," the "multiplication of effects" and their "segregation," continuing until it ceases in complete "equilibration" Sooner or later, however, the reverse process of Dissolution, with its absorption of motion and disintegration of matter must prevail, and these oscillations of the cosmic process will continue without end It appears, therefore, that Spencer ultimately describes the Knowable in terms of the mechanical conceptions of matter and motion, and this gives a materialistic colouring to his philosophy

In the *Principles of Biology* (1864) the chief points are the definition of life as the continuous adjustment of internal to external relations, and the consequent emphasis on the need of adapting the organism to its environment This does not sufficiently recognize that the higher organisms largely adjust external to internal relations and adapt their environment to their needs His universal process of Evolution seems to give Spencer a criterion of "higher" and "lower" "progression" and "degeneration," independent of the accidents of actual history The higher (at least in times of "evolution") is the more complex, whether it invariably survives or not On the other hand, he advances too easily from the maxim that function is prior to structure to the conclusion that the results of use and disuse are immediately incarnate in structural adaptations capable of hereditary transmission, an inference that has involved him in controversy with Weismann's school

In his *Principles of Psychology* (1870–72) Spencer advocates the genetic explanation of the phenomena of the adult human mind by reference to its infant and animal ancestry. On the fundamental question, however, of the psychophysical connection and the derivation of mind from matter, his utterances are neither clear nor consistent On the one hand, his whole formulation of Evolution in mechanical terms urges him to compose the mind out of homogeneous units of consciousness (or "feeling") "similar in nature to those which we know as nervous shocks; each of which is the correlative of a rhythmical motion of a material unit or group of such units" (§ 62); on the other hand, he is ready to amend *nervous* into *psychical* shocks, which is no doubt what he ought to have meant but could not say without ruining the illusory bridge between the psychical and the physiological which is suggested in the phrase "nervous shock." And he admits (§ 63) that if we were compelled to choose between translating mental phenomena into physical and its converse, the latter would be preferable. But he finally leaves the relation between the unknowable "substance of Mind" and the unknowable "substance of Matter" to the Unknowable To the theory of knowledge Spencer contributes a "transfigured realism," to mediate between realism and idealism, and the doctrine that "necessary truths," acquired in experience and congenitally transmitted, are *a priori* to the individual, though *a posteriori* to the race, to mediate between empiricism and apriorism

In the *Principles of Sociology* (1877–96) Spencer's most influential ideas have been that of the social organism, of the origination of religion out of the worship of ancestral ghosts, of the natural antagonism between nutrition and reproduction, industrialism and warfare. Politically, Spencer was an individualist of an extreme *laissez faire* type, and it is in his political attitude that the consequences of his pre-Darwinian conception of Evolution are most manifest. But for this, he would hardly have established so absolute an antithesis between industrial and military competition, and would have been readier to see that the law of the struggle for existence, just because it is universal and equally (though differently) operative in every form of society, cannot be appealed to for guidance in deciding between the merits of an industrial or military and of an individualist or socialist society.

In the *Principles of Ethics* Spencer, though relying on the intrinsic consequences of actions for the guidance of conduct, conceives the ethical end in a manner intermediate between the hedonist and the evolutionist. The transition from the evolutionist criterion of survival to the criterion of happiness is effected by means of the psychological argument that pleasure promotes function and that living beings must, upon pain of extinction, take pleasure in actions conducive to their survival Conduct being the adjustment of acts to ends, and good conduct that which is conducive to the preservation of a pleasurable life in a society so adjusted that each attains his happiness without impeding that of others, life is valuable only if it conduces to happiness On the other hand, life must in the long run so conduce because a constant process of adjustment is going on which is bound to lead to a complete adjustment which will be perfect happiness. Spencer concludes that the sense of duty must diminish as moralization increases In this reasoning Spencer overlooks the possibility of an expansion of the ethical environment If this is as rapid as the rate of adaptation, there will be no actual growth of adaptation and so no moral progress Complete adaptation to an infinitely receding ideal is impossible, but Spencer considers that he can both anticipate such a state, and lay down the rules obtaining in it, which will constitute the code of "Absolute Ethics" He conceives it as a state of social harmony so complete that even the antagonism between altruism and egoism will have been overcome; everyone will derive egoistic pleasure from doing such altruistic acts as may still be needed. Originally the socially salutary action was in the main that which was enjoined on the individual by his political and religious superiors and by social sentiment; it was also in the main that to which his higher, more complex and re-representative feelings prompted Hence the fear with which the political, religious and social controls were regarded came to be associated also with the specifically moral control of lower by higher feelings, and engendered by coercive element in the feeling of obligation Its authoritativeness depends on the intrinsic salutariness of self-control, and must cease with the resistance of the lower feelings Hence Spencer concludes that the sense of duty must diminish as moralization increases In the preface to the last part of his *Ethics* (1893) Spencer regrets that "the Doctrine of Evolution has not furnished guidance to the extent he had hoped," but his contributions to ethics are not unlikely to be the most permanently valuable part of his philosophy.

After completing his system (1896) Spencer continued to revise it, and brought out new editions of the *Biology* (1898–99) and *First Principles* (1900) The dates of his chief works are as follows 1842, Letters to the *Nonconformist, "The Proper Sphere of Government"*; 1850, *Social Statics*; 1852, *The Theory of Population* (*cf* part vi of *Biology*), "The Development Hypothesis" (in *Essays,* vol i) 1853; *The Universal Postulate* (cf *Psychology,* part vii); 1854, "the Genesis of Science" (in *Essays,* vol ii); 1855, *Principles of Psychology* (1 vol); 1857, *Progress, its Law and Cause* (*Essays,* vol i) 1858, *Essays* (containing most of his contributions to the *Westminster Review*; 1863, vol ii; 1885, vol iii.); 1861, *Education· Intellectual, Moral, Physical,* 1862, *First Principles* (2nd ed., 1867, 6th, 1900); 1864–67, *Principles of Biology* (2 vols); 1872, *Principles of Psychology* (2nd ed., in 2 vols); 1873, *The Study of Sociology*; 1876, vol i, *The Principles of Sociology*; vol ii, *Ceremonial Institutions,* 1879, *Political Institutions,* 1882; vol iii., *Ecclesiastical Institutions,* 1885, completed 1896; 1879, *The Data of*

Ethics (part i of *Principles of Ethics* in 2 vols.; part iv., *Justice*, 1891; parts ii. and iii., *Inductions of Ethics* and *Ethics of Individual Life*, 1892; parts v. and vi., *Negative and Positive Beneficence*, 1893). 1884, *Man versus the State*. 1886, *Factors of Organic Evolution*. 1893, *Inadequacy of Natural Selection*. 1894, *A Rejoinder to Professor Weismann* and *Weismannism once more*. 1897, *Fragments*. 1902, *Facts and Comments*. An *Autobiography* in 2 vols. appeared posthumously in 1904. For a useful summary of his chief doctrines by Spencer himself *see* his preface to Collins's *Epitome of the Synthetic Philosophy*; *see* also: J. A. Thompson, *H. Spencer* (1906); W. H. Hudson, *H. Spencer* (1908).

SPENCER, JOHN CHARLES SPENCER, 3RD EARL (1782–1845), English statesman, better known by the courtesy title of Lord Althorp, which he bore during his father's lifetime, was the son of George John, 2nd Earl (1758–1834), who served in the ministries of Pitt, Fox and Grenville, and was first lord of the admiralty from 1794–1801. John Charles was born at Spencer House, London, on May 30, 1782, and was educated at Trinity college, Cambridge. He represented Okehampton (1804), St. Albans (1806) and Northamptonshire (1806). When Lord Grey's administration was formed at the close of 1830 the chancellorship of the exchequer combined with the leadership of the House of Commons was entrusted to Lord Althorp. The budget was a failure, but this misfortune was soon forgotten in the struggles over the Reform bill, in the preparation and success of which Lord Althorp played an important part.

The death of the 2nd Earl Spencer in Nov. 1834, called his son to the upper house and was the occasion of Melbourne's dismissal by King William IV. He was the first president of the Royal Agricultural Society (founded 1838), and a notable cattle-breeder. He died at Wiseton on Oct. 1, 1845.

See Sir Denis Le Marchant, *Memoir* (1876); W. Bagehot, *Biographical Studies* (1881); E. J. Myers, *Lord Althorp* (1890).

SPENCER, JOHN POYNTZ SPENCER, 5th EARL (1835–1910), English statesman, was the son of the 4th Earl and his first wife. Born on Oct. 27, 1835, and educated at Harrow and Trinity college, Cambridge, he was a member of parliament for a few months before he succeeded to the earldom in Dec. 1857. His long career as a Liberal politician dates from his acceptance of the office of lord-lieutenant of Ireland under Gladstone in 1868, a post which he retained until 1874. When the Liberals returned to power in 1880 he was appointed lord president of the council, but in 1882 he entered upon a second term of office as lord-lieutenant of Ireland. In the Liberal administration of 1886 he was lord-president of the council, and from 1892 to 1895 he was first lord of the admiralty. From 1902 to 1905 he was the Liberal leader in the House of Lords, and early in 1905, was discussed as a possible Liberal prime minister. He died on Aug. 13, 1910. The fine library, collected at Althorp by the 2nd earl, was sold by him for £250,000 to Mrs. Rylands, the widow of a Manchester merchant, who presented it to that city.

SPENCER, a town of Worcester county, Massachusetts, U.S.A. Pop. (1920) 5,930. Spencer was settled in 1721 and incorporated in 1753. One of its houses was the birthplace of three inventors: William Howe, Tyler Howe and Elias Howe, Jr., who invented respectively the "Howe truss" bridge, the spring bed and the sewing machine.

SPENDER, JOHN ALFRED (1862–), British journalist, was born at Bath, the son of a doctor, and educated at Bath College, and at Balliol College, Oxford. Adopting the career of a journalist, he was editor of *The Eastern Morning News* from 1886 to 1890 and then on the staff of *The Pall Mall Gazette* in London. When the *Westminster Gazette* was established in 1893, he became an assistant editor and from 1896 to 1922 was its editor, leaving just after it became a morning paper. As editor of the *Westminster* Spender won general respect, not only as a brilliant writer but as the possessor of an exceptionally fair and balanced mind. He held a high place in the councils of the Liberal party and his services to the state included membership of the royal commission on divorce and of the Milner Mission to Egypt. A slight volume, *The Comments of Bagshot* (1914), reveals Mr. Spender at his best. He has also written *The Indian Scene* (1912); *The Foundations of British Policy* (1917); and *The Life of Sir H. Campbell-Bannerman* (1923). His memoirs appeared in 1926, *Life, Journalism, and Politics* (2 vols.).

SPENER, PHILIPP JAKOB (1635–1705), German theologian, was born on Jan. 13, 1635, at Rappoltsweiler in Upper Alsace. He won his degree of master at Strasbourg (1653) by a disputation against the philosophy of Hobbes. In 1666, he was chief pastor in the Lutheran Church at Frankfort-on-Main. Here he published his two chief works, *Pia desideria* (1675) and *Allgemeine Gottesgelehrtheit* (1680), and began that form of pastoral work which resulted in the movement called *Pietism*. In 1686 he accepted the invitation to the first court chaplaincy at Dresden. But the elector John George III. was offended by his chaplain's candour. Spener refused to resign his post, and the Saxon government hesitated to dismiss him. The difficulty was solved by his promotion (1691) to the rectorship of St. Nicholas in Berlin with the title of "Konsistorialrat." The university of Halle was founded under his influence in 1694. Spener was exposed to the abuse of orthodox Lutheran theologians. In 1695 the theological faculty of Wittenberg formally laid to his charge 264 errors. He died on Feb. 5, 1705. His last important work was *Theologische Bedenken* (4 vols., 1700–02), to which was added after his death *Letzte theologische Bedenken*, with a biography of Spener by C. H. von Canstein (1711). Though "the father of Pietism," the extravagances of the movement cannot be ascribed to him personally.

Spener was a voluminous writer. The list of his published works comprises 7 vols. folio, 63 quarto, 7 octavo, 46 duodecimo; a new edition of his chief writings was published by P. Grünberg in 1889. *See* W. Hossbach, *Philipp Jakob Spener und seine Zeit* (1828, 3rd ed., 1861); A. Ritschl, *Geschichte des Pietismus*, ii. (1884); E. Sachsse, *Ursprung und Wesen des Pietismus* (1884); P. Grünberg, *P. J. Spener* (3 vols., 1893–1906).

SPENGLER, OSWALD (1880–), German philosopher, was born at Blankenburg in the Harz on May 29, 1880. He studied mathematics and natural history, with history and art. This rare combination is the foundation of the peculiar character of Spengler's work, in which unexpected parallels between scientific truths of physics and mathematics and the artistic and other cultural achievements of an epoch of history are drawn. He completed in 1914 the first version of *Der Untergang des Abendlandes* (1918, rev. ed. 1922; Eng. trans. *The Decline of the West*, by C. F. Atkinson).

Other works of Spengler, chiefly concerned with contemporary political problems are: *Preussentum und Sozialismus* (1920); *Pessimismus* (1921); *Politische Pflichten der deutschen Jugend* (1924); *Neubau des deutschen Reiches* (1924).

See M. Schroeter, *Der Streit um Spengler, etc.* (1922).

SPENSER, EDMUND (?1552–1599), "the prince of poets in his time," was born in London—Oldys says, in East Smithfield—probably in 1552, possibly in 1549. (The date depends on whether Sonnet 60, written when Spenser was 41, belongs to 1593 or to 1590: *v. infra*.) His mother's name, he tells us, was Elizabeth: his father has been conjecturally identified with John Spenser, a journeyman cloth-maker. Later, the poet claimed kindred with the Spencers of Althorpe in Northamptonshire, and had his claim allowed; but the poverty of his home is shown by the grants made to him out of the Nowell bequest as a poor scholar of Merchant Taylors' school. There, under the great Mulcaster, he laid the foundations of his wide, if inexact, scholarship; best of all, he learned from Mulcaster to "worship the English," and to believe it as capable of great poetry as any language. He was still at school when, in 1569, he supplied some verse translations from Marot and du Bellay to Van der Noodt's *Theatre of Worldlings*. Van der Noodt, it is true, took the credit of these verses to himself: but they were included, with some alterations, in the *Complaints* volume of 1591 (*v. infra*), and we need not doubt that they are Spenser's. The rhymed stanzas after Marot at least bear his mark: the blank-verse renderings from du Bellay are inferior, and were considerably altered and tagged with rhymes for the re-issue of 1591.

In this same year he entered Pembroke hall, Cambridge, as a sizar, matriculating on May 20. He remained at Cambridge for seven years, as was then not unusual, proceeding B.A. in 1572 and commencing M.A. in 1576. His health was poor; but he read

widely, especially in philosophy and rhetoric, studying Italian as well as Latin, Greek and French, and training himself for poetry. His studies profited from the friendship of Gabriel Harvey, a fellow of his college, a conceited pedant, but a real scholar, and sincerely attached to Spenser, though his friendship may not always have been quite disinterested nor his literary advice wise. Literature, however, stirred the mind of Cambridge less than theology. In the ecclesiastical controversy with which the university had seethed ever since Cartwright's brief tenure of the chair of divinity (1569–70), Spenser took the Puritan side But he was neither sectary nor ascetic He had a hatred of popery (inflamed by the Bartholomew massacre) and contempt for the hirelings who "for their bellies' sake" had climbed into the Anglican fold

What he did on leaving Cambridge is still a mystery He had missed his fellowship, and must look about him for a profession or a patron The view that he went to live with relatives in Lancashire, though buttressed by appeals to family tradition and to the language and scenery of the *Calender,* rests at bottom on no ascertained fact

But in the "North-parts" (Drayton brings Rosalind to the Cotswolds; Aubrey says that she was related to Sir Erasmus Darwin's lady, who was a Wilkes of Hodnell in Warwickshire), Spenser fell in love with the Rosalind of the *Shepheardes Calender,* of whom again we can say only that she was a lady of higher rank than his, who enjoyed, but did not reward, her young poet's devotion In 1577 we seem to get a glimpse of Spenser in an unexpected quarter In the *View of the Present State of Ireland* Irenaeus tells how he witnessed the execution of Murrogh O'Brien, which took place at Limerick in July, 1577 In the rest of that dialogue Irenaeus represents Spenser himself, and it is natural though not inevitable to conclude that he does so in this place also. But no other evidence has been found for this visit, Phillips's statement that Spenser was secretary to Sir Henry Sidney may be discounted, since he has probably confused Sidney with Grey. Yet Irenaeus's account of this hideous incident reads like the words of an eye-witness, and the visit, if it occurred, would point to a connection with the Sidney-Leicester circle earlier than 1579.

After this we are on firmer ground We know that in 1578 Spenser was secretary to John Young, bishop of Rochester, who had been master of Pembroke hall while Spenser was a student. The bishop of Rochester (*Episcopus Roffensis*) is the Roffyn of the *Shepheardes Calender*· the fable of Roffyn's dog and the wolf may glance at the old Roman Catholic bishop, Thomas Watson, who was committed to Young's custody in Feb. 1579 Much of the *Shepheardes Calender* was apparently written at Rochester, where also Spenser first conceived the idea of the wedding of Thames and Medway. If Spenser at this time thought of entering the Church, he changed his mind on a nearer view of its condition, for by Easter 1579 he was in Westminster, sharing rooms with Harvey and holding "long conference" with him There was a third party to their discussions, one "E K ," to be identified probably with Edward Kirke, once a fellow-sizar of Spenser's at Pembroke The notion that E K is a mask for Spenser himself has been disproved by Dr Herford It is not unlikely, indeed, that the "Mistress Kerke" in Westminster, who took charge of letters for Spenser in October of this year, was E K 's mother, and that all three were living in her house Among other things they discussed Spenser's *début* as an author. He had several pieces ready or nearly ready—*Dreams, Legends, Court of Cupid, Pageants, The English Poet* (in prose), and the *Shepheardes Calender* It was decided to bring out the last, and to bring it out in classical style with introduction, notes and glossary by E K , even as Muretus edited the first book of Ronsard's *Amours* E K. wrote the introduction forthwith—it is dated from London, April 10, 1579—and got to work on the notes

Harvey's Letter-book gives us an amusing picture of Spenser that summer. He is reading some law, evidently with an eye to diplomatic or administrative work; he has blossomed into a courtier and a gallant, bearded and moustachioed, Italianate, Frenchified. At what date, and in what sense, he entered Leicester's service we do not know precisely At all events on Oct. 5 he writes from Leicester house to tell Harvey that he expects to go abroad in a week, "most what" at Leicester's charges—the "most what" shows that he was not entirely dependent on Leicester's bounty—and that "gentle Mr Sidney" has proposed that they two should correspond. The tour apparently never took place, for his next letter of ten days later says no word about it, but is all concerned with quantitative verse and with doubts about the publication of his *Slumbers.* He has been to Court and expects to go again, Sidney and Dyer have him "in some use of familiarity" The *Shepheardes Calender* was licensed on Dec. 5, and published anonymously; the dedication to Sidney is by "Immerito"

The Shepheardes Calender.—The *Calender* consists of 12 pastoral eclogues in the artificial style of Virgil, Mantuan, Sanazzaro and Marot, which admits real persons and current events in a pastoral guise. From all these precursors Spenser borrowed ostentatiously, above all from Marot, whom E K nevertheless belittles, perhaps because the Pléiade had eclipsed him. Derivative and conventional as it is, the *Calender* made an epoch in English literary history, not so much by naturalising pastoralism as by showing (under cover of the pastoral convention) what English could do in many kinds and metres. The couplets of the satires and fables are intentionally rude, and the rhymeless sestina is mere virtuosity; but the elegiac stanzas of the complaints recaptured the metrical secret of Chaucer, and the lyric staves of the paean and the dirge extended the range of English song In all these measures he made free use of alliteration, dear to English ears, though abused by his contemporaries and frowned on by the classicists For his reform of poetic diction Spenser had before him the example and precepts of the Pléiade Like them he sought to embellish the beggarly vocabulary of contemporary verse, partly by foreign loan-words, but mainly by drawing on native sources, by archaisms, pseudo-archaisms and dialect words He was in search of a vocabulary fit for the heroical poem that he already contemplated But the new poet had to care not only for words but for the order of his words and the structure and juncture of his sentences Here Spenser scored his greatest success, eschewing obscurity and looseness, and giving his syntax a movement, too copious perhaps, but admirably fluent, in lucid, easy yet well-knit sentences Syntactically, Spenser is one of the simplest of poets

The *Shepheardes Calender* may not have fulfilled all Spenser's hopes, but it went into a second edition in 1581 Sidney praised it judiciously, or judicially, but durst not approve its rustic diction. However, Spenser had many other arrows in his quiver In April 1580 he is full of projects for the immediate publication of his *Dying Pelican* and *Dreams;* his Latin *Stemmata Dudleiana* will need "more advisement" before it can be "sent abroade," but the quantitative *Epithalamion Thamesis* shall be "shortly set forth" Under the influence of Sidney, Dyer and Drant, he had come for the moment to take quantitative verse more seriously But he is more eager to proceed with the *Faerie Queene,* of which he sent Harvey specimens Harvey thought little of them, preferring the (lost) *Nine Comedies* in the manner of Ariosto Moreover, the poet is in love again, this time with better hopes Harvey's compliments to *Mea Domina Immerito, Mea Bellissima Collina Clouta,* taken with an obscure passage in *Daphnaida* (ll 64–66), which reads like consolation tendered by one widower to another, have led some scholars to believe that Spenser married this "second Rosalind" But there is no other evidence for the marriage, nor is the lady ever heard of again These letters of April 1580 give no hint of any friction with Leicester But now Spenser seems to have made a false step The queen had dallied for years with the project of marrying the duke of Alençon In Jan 1579 his agent Simier came to England and Alençon himself paid a flying visit in August to press his suit in person. He was ugly, dwarfish and half her age, but the queen smiled on him, called him her "grenouille" and Simier her "petit singe." The Puritans took alarm. Sidney remonstrated in such plain terms that the queen forbade him the Court He retired to Wilton to write his *Arcadia,* and Spenser probably never saw him again. This was in Jan. 1580

It was at this juncture apparently that Spenser drew his pen He had begun a *fabliau* of an ape and a fox, satirising the Parson

Trullibers and other humbugs of the day. Now, catching at Elizabeth's trick of animal nick-names, he brought his ape and fox to a court of beasts. The ape becomes Alençon-Simier, the fox is Burghley, who was believed to favour the marriage. Their misrule when they have stolen the lion's skin foreshadows the fate of England under a French king-consort. But Spenser misjudged the situation. Leicester had concluded that the wind stood fair for France, and trimmed his sails accordingly. Spenser was snubbed, and the satire, which was circulating in manuscript as *Mother Hubberds Tale,* was called in, but not before it had come to Burghley's ears. The tale of Spenser's discomfiture is told in *Virgils Gnat,* killed by the man whose life it had saved. Such is the most plausible explanation of this obscure episode. At all events, abandoning all his projects of publication, Spenser accepted a secretaryship to Lord Grey of Wilton, the newly appointed Lord Deputy of Ireland.

In Ireland.—Grey landed in Dublin in Aug. 1580 and set himself at once to the task of suppressing Desmond's rebellion. He was a stern Puritan, to whom the pope was Anti-christ and the Papist rebels were traitors at once to God and their queen. Spenser soon had proof of his quality. A band of Spanish and Italian filibusters had landed in Kerry to support the Munster rebels and occupied a fort near Smerwick. Grey marched against them, forced them to surrender unconditionally, held the officers to ransom, and put the men to the sword. Then he ravaged Munster, leaving famine to complete the work. On campaigns Spenser saw "such wretchednesse as that any stonye harte would have rued the same." With Grey's recall in 1582 Spenser lost his secretaryship; but in the previous year he had acquired a clerkship for the faculties (*i.e.,* licences and dispensations) in the Dublin chancery; and he had begun to obtain leases of forfeited houses and lands at modest rents which he did not always pay. At one of these houses, New Abbey in Co. Kildare, he seems to have resided occasionally in 1583 and 1584. But his headquarters were still in Dublin. We get a pleasant glimpse of him there in Ludovick Bryskett's *Discourse of Civil Life.* Bryskett tells us how a distinguished company, including the primate of Armagh, and soldiers like Norreys and St. Leger, met at his cottage near Dublin. Spenser suggested that their host should read them his translation of Giraldi da Cinthio's *Discourse of Civill Life;* which Bryskett accordingly did. The reading lasted for three days, being interspersed with discussions. On the third day Spenser interposed again, urging (to our astonishment) Aristotelian objections to the immortality of the soul. But Bryskett is simply putting into his mouth the arguments given by Giraldi to Torquato. It is doubtful, indeed, if this famous discussion ever took place at all, for Bryskett imitates Giraldi not only in the substance of his dialogue but in its setting. But if it never actually occurred it must be such as might have occurred.

In 1585 the centre of Spenser's interests began to shift to Munster. In that year he is found acting as deputy to Ludovick Bryskett in the clerkship of the council of Munster. In 1586 he held the prebend of Effin in Co. Limerick; and in that same year, under the Government's scheme for the plantation of Munster, he obtained a perpetual lease of Kilcolman Castle in Co. Cork with 3,028 acres of land. His resignation of his clerkship for the faculties in 1588 probably means that he then began to live at Kilcolman, where tradition says that his sister Sarah kept house for him. Here in 1589 he received a momentous visit from Raleigh. He had been engaged on the *Faerie Queene* intermittently for nearly ten years, receiving a fresh stimulus from Tasso's *Gerusalemme Liberata,* which reached him probably about the time of Lord Grey's recall. By 1589 three books were completed. Raleigh at once perceived their superlative merits and carried Spenser off to England to lay his poem at the queen's feet. It was licensed on Dec. 1, 1589 and published in 1590 with a dedication to the queen. Its reception can only be described as reverential. The great English epic so long awaited had appeared.

Spenser remained in England for more than a year, enjoying his fame, making friends with brother-poets, entertained at country houses, and acknowledged by his kinswomen of Althorpe, Lady Carey, Lady Strange, and Lady Compton and Mountegle. But Burghley had not forgiven him; the substantial preferment for which he hoped was whittled down to a pension of £50 a year, and in 1591 he returned to Ireland a disappointed man. Before leaving, he arranged for the publication of some of his minor poems, which appeared in 1591 as *Complaints.*

Complaints.—Of the *Complaints,* the *Visions of Petrarch* and *Visions of Bellay* are refurbishings of his schoolboy translations. *The Ruines of Rome,* a rendering of du Bellay's *Antiquitez de Rome,* is clearly a juvenile production also. In the same kind, but much superior, is the original *Visions of the Worlds Vanitie,* in which, from Harvey's remarks, we may fairly recognize a fragment of the *Dreams* of 1580. The *Teares of the Muses,* mentioned in *A Midsummer Night's Dream,* V. i. 52, where Theseus dismisses it as "some satire, keen and critical," is an unconvincing complaint of the neglect of poetry, more excusable in 1580 than in 1590. The *Ruines of Time* laments various members of the Dudley family, including Sidney and Leicester, who had died in the previous decade: its present form belongs to 1590; but it probably incorporates some material collected for the Latin *Stemmata Dudleiana;* and the "Pageants" at the end may be another fragment of the *Dreams. Mother Hubberds Tale* was strengthened by the addition of a brilliant and bitter denunciation of the wretchedness of the suitor's state; and Spenser bated no jot of his satire on Burghley. *Virgils Gnat,* a free rendering of the *Culex,* has already been described. The one entirely new poem in the volume is *Muiopotmos,* which clearly belongs to 1590. Its theme recalls Sonnet 71, and may have been suggested simply by the sight of Lady Carey at her drawn-work. In spite of the grim ending the tone is so light-hearted that it seems perverse to read an inner meaning into this "airy trifle," with Burghley as the spider. Yet no reader would have suspected an inner meaning in *Virgils Gnat* but for the dedication to Leicester.

On reaching home, or so he would have us believe, Spenser wrote *Colin Clouts Come Home Againe,* dedicating it to Raleigh "from my house of Kilcolman the 27. of December 1591."[1] It was not published, however, till 1595, when it appeared in one volume with *Astrophel.*

Colin Clout; Astrophel.—*Colin Clouts Come Home Againe* is the most charming of Spenser's poems. He is again in Arcady, telling his fellow-shepherds of his voyage with the Shepherd of the Ocean, his reception by the mighty Cynthia, her court, her ladies and brave poets. Then the note changes to the old complaint of courtly falsity and praise of the shepherd's life. The whole poem is exquisitely written, in "an easy running verse with tender feet." There is nothing more attractive in Spenser than Colin's chivalrous defence of Rosalind.

Astrophel is the prelude to a set of pastoral elegies on Sidney by several hands. The second "number," the *Lay of Clorinda,* though credited to Sidney's sister, is demonstrably from Spenser's pen. If *Astrophel* seems conventional and frigid we must remember that Spenser had already lamented Sidney in the *Ruines of Time,* and that the Sidney whom he now laments is not the hero of Zutphen but the author of the *Arcadia.*

Colin's praise of the shepherd's life prepares us to find that Spenser, though disappointed of preferment in England, and harassed by law-suits with his Irish neighbour Lord Roche, had begun to love his Munster home and to weave its legends and scenery into his verse. Towards the close of 1592, on the orthodox view of the *Amoretti,* he fell in love with Elizabeth Boyle and married her on June 11, 1594. He celebrated his wooing in the *Amoretti* and his wedding in the *Epithalamion,* which were entered together at Stationers' Hall in November 1594, and published together in 1595. It is highly probable that some of the *Amoretti* had already done service to express an *amour courtois* for Lady Carey during his English visit. It is probable that Elizabeth Boyle was the orphan daughter of Stephen Boyle, of Bradden in Northamptonshire, who had accompanied her brother

[1]Yet the dedication of *Daphnaida* is dated "London this first of Januairie, 1591" (*i.e.,* 1592 n.s.). No convincing explanation of this discrepancy has been offered. On the whole it is easiest to believe that Spenser, writing on New Year's Day, used the new style, *i.e.,* that his 1591 means our 1591.

Alexander when he went to Ireland to seek his fortune under the protection of their kinsman Richard Boyle, afterwards earl of Cork. The view that she was a widow, having been married to one Tristram Peace in 1588 or 1589, at present lacks documentary confirmation, and is hard to reconcile with Burke's statement that she bore seven children to her third—on this view her fourth—husband, Sir Robert Tynte, after 1612 or 1613

Amoretti; Epithalamion.—The *Amoretti* are love-sonnets, all but one in a form which Spenser made his own, consisting of three *linked* quatrains and a couplet. It had already been used in Scots, but Spenser may have got it direct from Marot. Though it lacks the pyramidal strength of the Petrarchan form, and the freedom of the Shakespearean, its "linked sweetness" suits Spenser's style. Many of these sonnets are imitated from French or Italian, especially from Desportes and Tasso: for one a Spanish original has been found. They are all graceful, but only the famous sonnet on Easter can be called great. The *Epithalamion*, on the other hand, is by common consent the greatest of all wedding-songs; rich in poetic allusions and in echoes from his own earlier poems, as if Spenser had gathered up all the fruits of his study and all the flowers of his fancy to present them to his bride. Here for once his whole nature speaks, flesh and spirit reconciled in the sacrament of marriage The stanza, suggested by the Italian canzone, is magnificent far beyond anything previously heard in English. The structure of the whole poem is as perfect as that of its parts.

Towards the end of 1595 Spenser, having finished three more books of the *Faerie Queene*, came to London to publish them. During this year he also published his *Prothalamion* and *Fowre Hymnes*, and composed or revised his *Veue of the Present State of Ireland*, which, though entered at Stationers' Hall in 1598, was not allowed to be printed without further authority, and, in fact, did not see the light till 1633.

Prothalamion; Hymnes; Veue of the Present State of Ireland.—The *Prothalamion* graced the wedding of two of the Earl of Bridgewater's daughters, who were married together from Essex house. Though it lacks the glow and sweep of the *Epithalamion*, it is, if possible, even more perfect in metre and diction.

The hymns of *Heavenlie Love* and *Heavenly Beauty* were written in 1596 to propitiate two pious noblewomen and counteract the hymns in *Honour of Love* and in *Honour of Beautie* written in his youth So Spenser avers; but to print the earlier hymns was scarcely the way to ensure their oblivion.

In the *Veue of the Present State of Ireland* Irenaeus expounds to Eudoxus the causes of the Irish troubles and propounds a cure Irish laws, customs and religion must all be reformed on the English model. But subjugation must precede reform. Vacillation has been the curse of the Government. Let them now bring over 10,000 foot and 1,000 horse, plant these in six convenient garrisons, give the rebels 20 days in which to surrender, and then hunt down relentlessly all who stand out. Two winter campaigns will break their spirit. Let a fresh offer of pardon then be made, and rebellion will be at an end. There follows a detailed scheme, supported by statistics, for the administration of the pacified areas, ending with a proposal for the appointment of a lieutenant-general, Essex being clearly indicated. Political antagonism and racial antipathy combined with religious hatred to blind Spenser to the Irish cause.

During this second visit to England Spenser's hopes of preferment were centred in the Earl of Essex, but again he sued in vain. He returned to Kilcolman, probably in 1597, and resumed the *Faerie Queene*. In Sept. 1598 he was recommended for the sheriffdom of Cork. But preferment came too late: in October Tyrone's rebellion had broken out, the Munster Irish rose, Kilcolman Castle was burned and Spenser fled with his family to Cork. From Cork he was sent to London with a dispatch which bears date Dec. 9, 1598. Along with it he brought a brief note of his own in which he reiterated the policy of the *View*. On Jan. 16, 1599 he died. He was buried in Westminster Abbey close to Chaucer; many nobles attended his funeral, and his fellow-poets brought elegies which they threw into his grave with the pens that had written them. Spenser's tragic reversal of fortune and sudden death gave rise to a crop of legends. Ben Jonson told Drummond that one of Spenser's children perished in the flames of Kilcolman Castle and that he himself died "for lack of bread" It is only too likely, after all he had gone through, that Spenser collapsed on reaching London, and was a dying man before his friends could learn of his condition and come to his aid. Two more cantos of the *Faerie Queene* with two stanzas of a third were published in 1609; if more was written, as is probable, after 1596, it is irrecoverably lost

The Faerie Queene.—Spenser's place among the great poets depends on the *Faerie Queene*, a fragment of a great poem which was to have been "disposed," as the title informs us, "into XII. bookes fashioning XII morall vertues," each virtue embodied in a knight, and the whole designed "to fashion a gentleman or noble person in vertuous and gentle discipline"—at once a chivalric romance and a handbook of morals and manners, nay more—for Spenser would emulate Virgil as well as Ariosto—a national epic to the glory of England's Elizabeth. Such a threefold cord is not easily twined Yet the task seemed feasible to Spenser, because to him the eternal war of good and evil, which was his essential theme, was embodied in the struggle of Protestant England against her Catholic foes. Book I. indeed may be read not inconsistently either as a mere romance, or as the spiritual experience of an elect Christian, or as a history of the English Church in the sixteenth century But in Book II. the story stands still for nearly two whole cantos, the tale of Hellenore in Book III is told with a gusto ill calculated to fashion a gentleman in virtuous discipline, in Book IV. the poet grows so careless of his characters that he lets the long-parted lovers come together without recognizing one another; the recent history of Book V has little allegorical or romantic interest; and Book VI ends in a burst of sheer pastoralism in which the poet forgets his allegory as completely as the hero forgets his quest. Only Spenser's contemporaries could fully appreciate the historical element, and some of it even to them can only have had the interest of a *roman à clef;* yet it strengthens the texture of the poem, and gives figures like Arthegall and Satyrane some firmness of outline

The allegory was treated with respect for two centuries; Milton thought "our sage and serious poet" a better teacher than Scotus or Aquinas; modern criticism has too often followed Hazlitt in commending the poem to readers with the assurance that the allegory won't bite them. But to ignore the allegory is to ignore the informing purpose of the whole, without which the story would be a mere series of ill-joined episodes, and much of the imagery meaningless, some of it grotesque or even repulsive. The ethical, as distinct from the structural, value of the allegory must depend on the worth of the ideas it embodies, as its poetical value depends on the imaginative force of their embodiment Spenser was not an original nor a systematic thinker. His philosophy is a blend of Platonism refracted through Ficino, Aristotelianism of the scholastic tradition, and Christianity with a Calvinistic bias And the elements do not perfectly combine Thus the doctrine of love and beauty, by which Ficino thought to reconcile the love of woman with the love of God, this doctrine, brilliantly expounded in the first two Hymns, is fundamentally irreconcilable with the scheme of salvation through the atoning sacrifice of Christ which is expounded in the third Hymn The poet was a sincere and militant Christian, but also a man sensitive to the allurements of the world and the flesh; he knew self-distrust, and weariness, and regret for evanescent youth, and is never so moving as when he writes out of such experiences or turns from this unstable life in longing for the eternal rest.

Of the romance itself, with its wealth of imagery and melody, there has never been but one opinion. Like all Spenser's work, it is highly imitative. He rifled romantic literature for incidents and situations. The descriptions in which he excels constantly recall works of art—picture, tapestry, pageant or masque. But he owed much also to real life; he was recommended for his sheriffdom as "not unskilful or without experience in the wars"; and his journeys through the wild woods of Munster and his intercourse with soldiers like Grey and Norreys yielded many a hint for the background and characters of the *F Q* Its diction,

archaic but not rustic, and rich in strange coinages and terms of chivalry, is in keeping with its remote and old-world air. Not less appropriate is the stanza which he invented, *not* by "extending" the ottava rima or the rhyme royal, but by adding to the linked quatrains which he had used in the *S.C.* an Alexandrine such as Ferrars had employed to tip his sestets. The elements are not new; the miracle lies in their combination. It is not a perfect stanza for narrative, nor indeed is Spenser a perfect story-teller; but its amplitude fits the slow *tempo* of his thought, as he unrolls his leisurely pageants or ponders on time and change. Its power must not be judged by single stanzas, but by the cumulative effect as stanza after stanza rolls in, each ninth wave breaking higher than the rest.

Spenser has not Chaucer's genial breadth, nor Milton's art, nor Wordsworth's vision; but in the purely poetic gifts he is inferior to Shakespeare alone. The "school of Spenser" was small and short-lived, quite eclipsed in the next generation by Jonson and Donne; but in a wider sense all later English poets have been his scholars.

Beeston described Spenser to Aubrey as a little man, with short hair, little band and little cuffs—a description that fits the Pembroke College portrait better than the beruffled exquisite of the Dupplin portrait. These two portraits, whether genuine or not, do aptly illustrate the two sides of Spenser, scholar and Puritan on the one hand, courtier and man of affairs on the other; fundamentally a poet, sensitive and fastidious, yet responsive to the claim of affection or of honour. "Entire affection hateth nicer hands"; "No service loathesome to a gentle kind"; "The noblest mind the best contentment has"—in such lines we hear his authentic voice.

Bibliography.—Dates of first issues are given above. Folios in 1609 (*F.Q.* only), 1611–13, 1617, 1670 (said to have been "overseen" by Dryden). Editions by J. Hughes (1715), H. J. Todd (1805), F. J. Child (1855), J. P. Collier (1862), R. Morris and J. W. Hales (1869), A. B. Grosart (1882–84), R. E. N. Dodge (1908), J. C. Smith and E. de Sélincourt (1909–10). *F.Q.* only by R. Church (1758), J. Upton (1758), K. M. Warren (1897–1900). *S.C.* by C. H. Herford (1895). *Fowre Hymnes* by L. Winstanley (1907). Commentaries and criticisms by J. Jortin (1714), T. Warton (1752), G. L. Craik (1845), R. W. Church (1879), J. J. Higginson (*S.C.* only) (1912), E. Legouis (1923), W. L. Renwick (1925). Much of the recent work on Spenser has been done by American scholars: F. I. Carpenter, E. A. Greenlaw, J. Erskine, J. B. Fletcher, P. W. Long, C. G. Osgood, F. M. Padelford, C. H. Whitman, etc. Most of it is available only in periodicals. Carpenter's *Reference Guide* (1923), Osgood's *Concordance* (1915), and Whitman's *Subject Index* (1918) are indispensable for detailed study.

(J. C. Sm.)

SPENSERIAN STANZA, a verse-form so called from its invention by Edmund Spenser for his *Faerie Queene* (1590). Its origin is disputed; Schipper derives it from the Old French ballade (*q.v.*), others from the Italian *ottava rima.* Probably, however, it is Chaucer's eight-line *Monk's Tale* stanza, with a ninth line (an alexandrine) added, a feature which gives the stanza its beauty. The rhyme-scheme is a b a b b c b c c + (the + denoting the extra foot in the last line). Spenser's sonnet-scheme is somewhat similar. The stanza was hardly used in the 17th century, though Giles and Phineas Fletcher made for themselves adaptations of it. About 1740 it was revived, by Akenside (*Virtuoso,* 1737), Shenstone (*Schoolmistress,* 1742) Thomson (*Castle of Indolence,* 1748); followed by Beattie (*Minstrel,* 1771) and Mrs. Tighe (*Psyche,* 1805). Since 1850 it has been rarely employed. It is a purely English form.

SPERANSKI, COUNT MIKHAIL MIKHAILOVICH (1772–1839), Russian statesman, the son of a village priest, spent his early days at the ecclesiastical seminary in St. Petersburg (Leningrad), where he rose to be professor of mathematics and physics. His brilliant intellectual qualities attracted the attention of the government, and he became secretary to Prince Kurakin. In 1806, the emperor Alexander I. took him to the conference of Erfurt and put him into direct communication with Napoleon, who described him as "the only clear head in Russia." They discussed Russian reforms.

From 1809 to 1812 Speranski was all-powerful; he replaced the earlier favourites, becoming practically sole minister. In 1810 and the first half of 1811 Speranski was still in high favour, and was the confidant of the emperor in that secret diplomacy which preceded the breach of Russia with Napoleon.

On the eve of the struggle with Napoleon, Alexander, conscious of his unpopularity, conceived the idea of making Speranski his scape-goat, and so mobilising Old Russian sentiment against revolutionary France. The grand-duchess Catherine, Karamzin, Rostopchin and the Swedish general Baron Armfield, intrigued to involve him in a charge of treason. Alexander did not credit the charge, but on March 29, 1812 he dismissed him from office. Reinstated in the public service in 1816, he was appointed governor-general of Siberia, for which he drew up a new scheme of government, and in 1821 entered the council of state. He died on Feb. 11, 1839, at St. Petersburg.

See the biography (in Russian) by M. Korff (St. Petersburg, 1861). On his public life and constitutional reforms *see* Theodor Schiemann, *Geschichte Russlands unter Kaiser Nikolaus I.,* Bd. i. *Kaiser Alexander I.* p. 75 *seq.* (Berlin, 1904); Pierre Chasles, *Le Parlement russe,* p. 19 *seq.* (Paris, 1910), and the works of V. Vagin (St. Petersburg, 1872 and Moscow, 1905). Count Nesselrode's letters to Speranski and many references are published in vol. iii. of the *Lettres et papiers du comte de Nesselrode.*

SPERMACETI, a wax found in the head cavities and blubber of the sperm-whale (*Physeter macrocephalus*), where it is dissolved in the sperm oil while the creature is living (from Lat. *sperma,* seed, and *cetus,* a whale). It also occurs in other Cetacea (*see* Whale Oils). It is mainly cetin or cetyl palmitate, $C_{15}H_{31}CO_2C_{16}H_{33}$. The substance is used in making candles, in the dressing of fabrics, in medicine and surgery, and in cosmetic preparations. (*See* Oils and Fats.)

SPERMOPHYTA, the name often used in botany to denote the seed-plants, including the true flowering plants, or angiosperms (*q.v.*), and the conifers and their allies or gymnosperms (*q.v.*). It is sometimes written "Spermatophyta."

SPERM-WHALE (*Physeter macrocephalus*), the largest of the toothed whales, called also cachalot, its size being about equal to those of the Arctic right-whale. The head is about one-third of the length of the body, massive, high, and truncated in front. It owes its size and form to the accumulation of a peculiar form of fatty tissue in the large hollow on the upper surface of the skull. The oil contained in cells in this cavity, when refined, yields spermaceti, and the sperm-oil of commerce is produced principally by the thick covering of blubber, which everywhere envelops the body. Ambergris, used in perfumery, is a concretion formed in the intestine, and found floating on the sea. (*See* Cetacea; Spermaceti.)

SPERRY, ELMER AMBROSE (1860–), American inventor, was born at Cortland, N.Y., on Oct. 12, 1860. He began early to experiment with electric arc lights and in 1879 established a factory in Chicago to manufacture an improved model which was highly successful. He then turned his attention to the development of electric mining machinery, invented the electric rotary and the chain undercutting machines, devised and built his own electric mining generator and other mining apparatus and established another factory to manufacture this machinery. He next designed an electric locomotive for industrial work, and developed motor and transmission machinery for street cars, which resulted in the founding of the Sperry Electric Railway Co. of Cleveland. About 1900 he established a research laboratory in electro-chemistry at Washington, D.C., where he invented the chlorine detinning process and also the electrolytic process for producing white lead from impure by-product lead. In 1915 he announced his high-intensity arc searchlight, built upon an entirely new principle, allowing a brilliancy as high as 900 candle-power per square millemetre, whereas 160 was the highest obtainable previously. The electrical and mechanical means of operating, as well as the mechanism to control the high temperatures of the arc, represented a difficult engineering achievement. These searchlights have become the standard for the principal armies and navies of the world and are in use for aircraft and coast beacons, the largest giving a white light of 1,500,000,000 candle-power which can be seen for upwards of 150 miles.

Sperry's most important inventions were based upon the application of the gyroscope in which he was always greatly interested.

Chief of these is the gyro-compass (*q v*), first installed on the battleship Delaware in 1911. This compass, unaffected as it is by iron and steel, has entirely superseded the magnetic compass on submarines and battleships and is rapidly being placed on merchant ships Upon it the whole complicated system of modern naval gunnery has been developed (*See* GUNNERY, NAVAL) Sperry also designed and manufactured electrically sustained gyros for torpedoes which enabled them to complete long trajectories with a high degree of accuracy During the World War he also developed aerial torpedoes with automatic gyro-control which proved effective at a range of 35 miles Quantity manufacture had begun when the war ended Further experiments yielded the gyro-pilot for the steering of ships, the automatic gyro-pilot for stabilizing aeroplanes, the gyroscopic roll and pitch recorder for the testing of ships, and, finally, a gyroscopic ship stabilizer, which has been installed on a number of ships in the United States, British, Italian and Japanese navies and promises to find a wider application The motion of a ship in the waves is almost completely neutralized by automatic counter movements of the gyroscopes. He has served since 1915 as a member of the naval consulting board, has published numerous scientific papers, and has been the recipient of many honours

See "The Engineering and Scientific Achievements of Elmer A Sperry," in *Mechanical Engineering*, vol xlix (1927)

SPES, properly *bona spes* ("good expectation," *i e*, hope), a goddess worshipped in Rome from an uncertain but doubtless early date (temple in the Forum Holitorium, or vegetable market, vowed during the first Punic War, *cf* Tibullus, i i, 9, *cf* ii. 6, 21) Possibly she was originally an agricultural deity, not the personification of hope in general

See Wissowa, *Religion und Kultus*, 2nd ed, p 329

SPESSART, a highland forest district belonging mainly to the Bavarian province of Lower Franconia, but in the north to the Prussian province of Hesse Cassel.

SPEUSIPPUS (4th century B C), Greek philosopher, son of Eurymedon and Potone, sister of Plato, is supposed to have been born *c* 407 B C He was bred in the school of Isocrates, but when Plato returned to Athens *c* 387 Speusippus became a member of the Academy In 361, when Plato undertook his third and last journey to Sicily, Speusippus accompanied him In 347 the dying philosopher nominated his nephew to succeed him as scholarch, and the choice was ratified by the school Speusippus held the office until his death in 339

Of Speusippus's many philosophical writings nothing survives except a fragment of a treatise *On Pythagorean Numbers* We gather (A) In regard to his theory of being (1) whereas Plato postulated as the basis of his system a cause which should be at once Unity, Good, and Mind, Speusippus distinguished Unity, the origin of things, from Good, their end, and both Unity and Good from controlling Mind or Reason, (2) whereas Plato recognized three kinds of numbers—firstly, ideal numbers, *i e*, the "determinants" or ideas, secondly, mathematical numbers, the abstractions of mathematics; and thirdly, sensible numbers, numbers embodied in things—Speusippus rejected the ideal numbers, and consequently the ideas, (3) Speusippus traced number, magnitude and soul each to a distinct principle of its own (B) In regard to his theory of knowledge (4) he held that a thing cannot be known apart from the knowledge of other things, for, that we may know what a thing is, we must know how it differs from other things, which other things must therefore be known, (5) accordingly, in the ten books of a work called Ὅμοια, he attempted a classification of plants and animals, (6) the results thus obtained he distinguished at once from "knowledge" and from "sensation" holding that "scientific observation" though it cannot attain to truth, may, nevertheless, in virtue of a certain acquired tact, frame "definitions" (C) In regard to his theory of ethics. (7) he denied that pleasure was a good, but seemingly was not prepared to account it an evil

Speusippus and his contemporaries exercised a far-reaching influence upon Academic doctrine When they rejected their master's ontology and proposed to themselves as ends mere classificatory sciences which with him had been means, they bartered their hope of philosophic certainty for the tentative results of scientific experience

F Ravaisson, *Speusippi de primis rerum principiis placita* (1838), Chr Aug Brandis, *Geschichte der griechisch-römischen Philosophie* (1853), II ii 1, Zeller, *Die Philosophie d Griechen* (Leipzig, 1875), II i, Mullach, *Frag Phil Graecorum*, iii (1881); and Überweg, *Grundriss der Gesch der Philosophie*, Bd I. (1926)

SPEY, river in the highlands of Scotland, rising in Mt Clach-a-Cheannaiche in Lochaber, in Inverness-shire A mile from its source it forms the small Loch Spey, and 31 m lower down the larger Loch Inch It falls by several mouths into the Moray Firth at Kingston It is about 110 m long It is a very rapid river, famous for salmon-fishing, and is nowhere navigable

SPEYER (Spires), a town and episcopal see of Germany, capital of the Bavarian palatinate, situated on the left bank of the Rhine, at the mouth of the Speyerbach, 16 m S of Mannheim by rail Pop (1925) 25,609 Speyer, known to the Romans as *Augusta Nemetum* or *Nemetae*, and to the Gauls as *Noviomagus*, appears under the form of Spira, about the 7th century Captured by Julius Caesar in 47 B C, it was repeatedly destroyed by the barbarian hordes in the first few centuries of the Christian era The town had become an episcopal seat in the 4th century, but heathenism supervened, and the present bishopric dates from 610 In 830 Speyer became part of the Frankish empire The contentions between the bishops and the citizens were as severe as in any other city of Germany The situation of the town opposite the mouths of several roads through the Rhine valley early fostered its trade, in 1294 it rose to be a free imperial city It enjoyed great renown as the seat of the imperial supreme court from 1527 till 1689 Numerous imperial diets assembled here From 1801 till 1814 it was the capital of a department of France, but it was restored to Bavaria in 1814

A basilica of sandstone, the cathedral has a peculiar importance in the history of architecture as probably the earliest Romanesque basilica in which the nave as well as the side arcades was vaulted from the first Built in 1030–1061 by Conrad II and his successor, this church has had a chequered history, its disasters culminating in 1689, when the soldiers of Louis XIV burned it to the bare walls, and scattered the ashes of eight German emperors Restored in 1772–1784 and provided with a vestibule and façade, it was again desecrated by the French in 1794, but in 1846–1853 it was once more thoroughly restored and adorned in the interior with gorgeous frescoes Speyer, although rebuilt in 1697, has never recovered from the injuries inflicted by the French in 1689 Its manufactures include paper, tobacco and cigars, sugar, machines, lead, vinegar, beer and musical instruments

SPEZIA, a city of Liguria, Italy, 49 ft above sea-level Pop (1926) 94,347 (commune) It is the chief naval harbour of Italy having been adopted as such in 1861 though Napoleon I had entertained the idea The Bay of Spezia (anc *Portus Lunae*) is sheltered from all except southerly winds, and on its western shore are numerous openings, which afford perfectly safe anchorage in all weathers The entrance is protected by forts, while a submarine embankment, 2 m long, renders it secure Its important arsenal dates from 1870 The establishment of San Vito is devoted entirely to the production of artillery, that of San Bartolomeo is exclusively used for electrical works and the manufacture of submarine weapons, especially torpedoes It is the headquarters of the northern naval command (*see* ITALY) The museum contains a unique collection of menhirs from the neighbourhood cut into the form of human figures Spezia probably arose after the destruction of Luna It was sold by the Fieschi in 1276 to Genoa The town was fortified by its new possessors and made the seat of a governor of some importance It became a city in the 16th century

SPHENE or **TITANITE,** a mineral consisting of calcium titano-silicate, $CaTiSiO_5$, crystallizing in the monoclinic system The crystals vary considerably in habit, but are generally thin and wedge-shaped, hence the name sphene (Gr σφήν, a wedge) The colour is green, yellow, brown or black, and the lustre resinous to adamantine, crystals are transparent to opaque The hardness is

5·5, specific gravity 3·5. Sphene is cut as a gem-stone, though it is rather too soft to stand much wear; owing to its high dispersive power it gives brilliant flashes of prismatic colours. As small crystals, it is found in igneous rocks (granite, syenite, trachyte, phonolite, etc.), and also in gneiss, schist and crystalline limestone.

SPHENISCIDAE: *see* PENGUIN.

SPHENODON: *see* REPTILES.

SPHERE, in Greek geometry, the solid generated by the revolution of a semicircle about its diameter as an axis. In modern elementary geometry it is more generally considered as the spherical surface so generated, or as the locus of points at a constant distance from a fixed point called the *centre.* The constant distance is called a *radius,* and any line segment through the centre and limited at both ends by the sphere is called a *diameter.* In the geometry of surfaces it is defined as the quadric surface passing through the circle at infinity. Any section made by a plane cutting a sphere is a circle, being a *great circle* if the plane passes through the centre, and otherwise a *small circle.* The solid cut off by the plane of a great circle, is a *hemisphere;* that cut off by the plane of a small circle, a *segment.* In analytical geometery, the equation of a sphere in rectangular Cartesian co-ordinates is $x^2+y^2+z^2=a^2$, and in polar co-ordinates it is $r=a$. If the centre is (α, β, γ), the Cartesian equation becomes

$$(x-\alpha)^2+(y-\beta)^2+(z-\gamma)^2=a^2.$$

The surface of a sphere is found by the formula $S=4\pi r^2$, the area being four times that of a great circle. The volume is $\frac{4}{3}\pi r^3$. Analogous to the propositions of plane geometry and trigonometry is a series of propositions relating to the sphere. (*See* GEODESY, ASTRONOMY, SURFACES, ANALYTIC GEOMETRY, PROJECTIVE GEOMETRY, SOLIDS [Geometric], TRIGONOMETRY.)

SPHERES OF INFLUENCE. "Spheres of influence," "spheres of action, "spheres of interest," "zones of influence," "field of operations," "Machtsphäre," "Interessensphäre," are regions as to which nations have agreed that one or more of them shall have exclusive liberty of action. These phrases became common after 1882, when the "scramble for Africa" began.

Among treaties defining such spheres are the following:

Great Britain and Portugal as to Africa, Aug. 20, 1890, Nov. 14, 1890 and June 11, 1891. Great Britain and France as to Upper Niger, Jan. 20, 1891; Nov. 15, 1893, as to Lake Chad. Great Britain and France as to Siam, Jan. 15, 1896. The two Governments engage to one another "that neither of them will, without the consent of the other in any case or under any pretext, advance their armed forces into the regions, etc." They also engage not to acquire within this region any special privilege or advantage which shall not be enjoyed in common, or equally open to Great Britain and France or their nationals and dependants. Great Britain and Italy as to Africa, April 15, 1891; May 5, 1894, as to region of the Gulf of Aden. Congo and Portugal, May 25, 1891, as to "sphères de souveraineté et d'influence" in the region of Lunda. Great Britain, Belgium and Congo, May 12, 1894, as to the sphere of influence of the independent Congo State. Great Britain and Germany, July 1, 1890 and Nov. 15, 1893, as to East and Central Africa. Great Britain and Russia as to the spheres of influence to the east of Lake Victoria in the Pamir region, March 11, 1895.

Being the result of treaties, arrangements as to spheres of influence bind only the parties thereto. As Olney, in his correspondence with Lord Salisbury in regard to Venezuela, remarked: "Arrangements as to spheres of influence are new departures, which certain great European Powers have found necessary and convenient in the course of their division among themselves of great tracts of the continent of Africa, and which find their sanction solely in their reciprocal obligations" (United States No. 2, 1896, p. 27). Some treaties declare that the arrangement shall not affect the rights of other powers (Stoerck, *Recueil,* xvi. p. 932).

Hinterland.—Claims somewhat similar to these embrace hinterland. Sometimes it is called the "doctrine of contiguity," or "droit de vicinité, de priorité, de préemption ou d'enclave." The occupation of the mouth of a river is constructive occupation of all its basin and tributaries.

A State, having actually occupied the coast, may claim to reserve to itself the right of occupying from time to time territory lying inland (hinterland). In the discussions as to the western boundary of Louisiana between the commissions of the United States and Spain, as to Oregon, as to the claims of the Portuguese in East Africa, and as to the boundaries of Venezuela, the question of the extent of the rights of the discoverer and occupier came up. Lord Salisbury referred to "the modern doctrine of hinterland with its inevitable contradictions" (United States, No. 2, 1896, p. 12). Certainly it is inconsistent with the doctrine, more and more received in recent times, that effective possession is necessary to found a title to sovereignty or control. The doctrine of the hinterland is likely to become less important, now that Africa has been parcelled out. *See* MANDATE, PROTECTORATE, SOVEREIGNTY.

SPHERICAL HARMONICS are certain functions which occur in the theories of gravitation, electricity, hydrodynamics, and many other branches of mathematical physics.

If a number of particles of masses $M_1, M_2, \cdots, M_m$, attracting according to the inverse-square law, are placed at points $A_1, A_2, \cdots, A_m$, the *potential* of these masses at any point P, *i.e.*, the work done by the gravitational attractions in bringing a unit mass from an infinite distance to P, is

$$\frac{M_1}{A_1P}+\frac{M_2}{A_2P}+\cdots+\frac{M_m}{A_mP}.$$

If now the points $A_1, A_2, \cdots, A_m, P$ are referred to a set of rectangular co-ordinate axes, and the co-ordinates of the points are $(a_1, b_1, c_1), (a_2, b_2, c_2), \cdots, (a_m, b_m, c_m), (x, y, z)$ so that

$$A_1P=\sqrt{\{(x-a_1)^2+(y-b_1)^2+(z-c_1)^2\}}$$

with similar expressions for $A_2P, A_3P, \cdots, A_mP$, and if V denotes the potential, it may be verified by partial differentiations that

$$\frac{\partial^2 V}{\partial x^2}+\frac{\partial^2 V}{\partial y^2}+\frac{\partial^2 V}{\partial z^2}=0.$$

This equation does not involve the masses or the points at which they are placed, and so it is satisfied by the potential produced at a point (x, y, z), in free space, by any gravitating system; it is known as *Laplace's equation,* and it is frequently written in the form

$$\nabla^2 V=0,$$

∇^2 denoting the differential operator $\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2}$ for brevity.

Laplace's equation occurs in problems of Gravitation, Electrostatics and Hydrodynamics; the related equation $\nabla^2 V=k\partial V/\partial t$ occurs in problems of conduction of heat, V being then a function of the co-ordinates x, y, z, and the time t, and k being a constant; and the equation $c^2\nabla^2 V=\partial^2 V/\partial t^2$ occurs in problems of Vibrations of air and aether, c being the velocity of sound or of light, according to the problem considered.

In order to discuss generally problems concerning the potential, it is found more effective to examine solutions of Laplace's equation than to regard the potential as the sum of a number of terms of the type M/AP, each term representing the potential produced by an attracting particle. If $V_1, V_2, V_3, \cdots$ are a number of solutions of Laplace's equation, and if

$$V=V_1+V_2+V_3+\cdots,$$

it is easily verified that

$$\nabla^2 V=\nabla^2 V_1+\nabla^2 V_2+\nabla^2 V_3+\cdots=0,$$

and so the sum of any number of solutions of Laplace's equation

is itself a solution of the equation. It is thus possible to build up a solution of Laplace's equation by adding together simpler solutions.

Now let V be any potential function, and suppose that it can be expanded by Taylor's theorem as a series of positive integral powers of x, y, z, thus

$$V = a_0+a_1x+b_1y+c_1z+a_2x^2+b_2y^2 \\ +c_2z^2+d_2yz+e_2zx+f_2xy+a_3x^3+\cdots.$$

Group together all terms which are of the same degree in x, y, z, and denote the groups of terms which are of degrees $0, 1, 2, \dots, n, \dots$ in the expansion by

$$Y_0(x, y, z),\quad Y_1(x, y, z),\quad Y_2(x, y, z),\quad \dots,\quad Y_n(x, y, z),\quad \dots$$

or, for brevity, by $Y_0, Y_1, Y_2, \dots, Y_n, \dots$, so that

$$V = Y_0+Y_1+Y_2+\dots+Y_n+\dots.$$

The expression $Y_n(x, y, z)$ is called *a spherical harmonic of degree n* It may be verified that

$$\nabla^2Y_2+\nabla^2Y_3+\dots+\nabla^2Y_n+\dots = \nabla^2V = 0$$

so that the expression on the left vanishes identically; and since the terms written down are of different degrees, $0, 1, \dots, n-2, \dots$, each must vanish separately, so that spherical harmonics are themselves solutions of Laplace's equation

If the polar co-ordinates of (x, y, z) are (r, θ, ϕ), so that

$$x = r\sin\theta\cos\phi,\quad y = r\sin\theta\sin\phi,\quad z = r\cos\theta,$$

then $Y_n(x,y,z)$ may be written in the form $r^nf_n(\theta,\phi)$, where $f_n(\theta,\phi)$ is independent of r, and $f_n(\theta, \phi)$ is called a *surface harmonic*

It can be proved that $Y_n(x, y, z)/r^{2n+1}$ is also a solution of Laplace's equation, and it is called a spherical harmonic of degree $-(n+1)$, this function and $Y_n(x, y, z)$ are called *solid* harmonics.

The term spherical harmonics (German, *Kugelfunktionen*, French, *Fonctions sphériques*) is due to Lord Kelvin

When referred to polar co-ordinates, Laplace's equation becomes

$$\frac{\partial}{\partial r}\left(r^2\frac{\partial V}{\partial r}\right)+\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial V}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2V}{\partial\phi^2}=0,$$

this was the form of the equation originally given by P S de Laplace in 1784, in a memoir on Saturn's rings

Determination of Harmonics of Given Degree.—Let $\sum a_{r,s,t}x^ry^sz^t$ be an arbitrary expression of positive integral degree n in x, y, z where r, s, t are positive integers (zero included) such that $r+s+t=n$, and the summation extends over all possible sets of values of r, s, t It is required to find conditions that this expression may be a harmonic

It is readily proved that the number of terms in the expression is $\frac{1}{2}(n+2)(n+1)$, if the expression is operated on by Laplace's operator, the result is an expression of degree $n-2$ in x, y, z, in which the $\frac{1}{2}n(n-1)$ coefficients are linear combinations of the $a_{r,s,t}$ If the last expression is equated to zero, $\frac{1}{2}n(n-1)$ equations connecting the $a_{r,s,t}$ are obtained, which have to be satisfied if the former expression is to be a harmonic It follows that the number of independent coefficients $a_{r,s,t}$ is

$$\tfrac{1}{2}(n+2)\ (n+1)-\tfrac{1}{2}n(n-1),$$

i e, $2n+1$, and the remaining coefficients are expressible linearly in terms of them

Consequently there are $2n+1$ independent harmonics of degree n, and any other harmonic of degree n is expressible as a linear combination of these harmonics

Take $n=2$ as an illustration, the expression

$$a_2x^2+b_2y^2+c_2z^2+2d_2yz+2e_2zx+2f_2xy$$

is a harmonic if $a_2+b_2+c_2=0$, and 5 independent harmonics of degree 2, in terms of which any harmonic of degree 2 may be expressed, may be taken to be

$$yz,\quad zx,\quad xy,\quad 2z^2-x^2-y^2,\quad x^2-y^2.$$

The next step is to construct $2n+1$ harmonics of degree n This may be effected by considering the condition that

$$(ax+by+cz)^n$$

may be a harmonic, where a, b, c, are constants, and deducing the harmonics from it By actual differentiation it follows that the condition that $(ax+by+cz)^n$ is a harmonic is

$$a^2+b^2+c^2 = 0,$$

and this condition is satisfied by taking

$$a = i\cos u,\quad b = i\sin u,\quad c = 1,$$

where u is any angle and i stands for $\sqrt{(-1)}$, and so

$$(z+ix\cos u+iy\sin u)^n$$

is always a harmonic

Now suppose this expression to be expanded by the multinomial theorem, and replace $\cos u$ and $\sin u$ by their exponential values $(e^{iu}+e^{-iu})/2$ and $(e^{iu}-e^{-iu})/(2i)$, when the products of powers of $\cos u$ and $\sin u$ are multiplied out in this way, replace expressions such as e^{miu}, e^{-miu} by $\cos mu\pm\sin mu$

It is thus possible to express $(z+ix\cos u+iy\sin u)^n$ in the form

$$(z+ix\cos u+iy\sin u)^n = \tfrac{1}{2}g_0(x,y,z) \\ +\sum_{m=1}^{n}[g_m(x,y,z)\cos mu+h_m(x,y,z)\sin mu],$$

where $g_m(x,y,z)$ and $h_m(x,y,z)$ are polynomials of degree n in x,y,z, and are independent of u, and since

$$\tfrac{1}{2}\nabla^2g_0(x,y,z)+\sum_{m=1}^{n}[\nabla^2g_m(x,y,z)\cos mu+\nabla^2h_m(x,y,z)\sin mu]\equiv0,$$

for all values of u, it is evident that $g_m(x,y,z)$ and $h_m(x,y,z)$ must be harmonics As an illustration,

$$(z+ix\cos u+iy\sin u)^2 = z^2-\tfrac{1}{2}x^2-\tfrac{1}{2}y^2+2ixz\cos u \\ +2iyz\sin u+\tfrac{1}{2}(y^2-x^2)\cos2u-xy\sin2u.$$

To obtain $g_m(x,y,z)$ and $h_m(x,y,z)$ explicitly, use Fourier's rule for determining the coefficients in a trigonometrical series, *i e*, multiply the expansion of $(z+ix\cos u+iy\sin u)^n$ by $\cos mu$ and by $\sin mu$, and integrate with respect to u from $-\pi$ to π It follows that

$$\pi g_m(x,y,z) = \int_{-\pi}^{\pi}(z+ix\cos u+iy\sin u)^n\cos mu\ du,$$

$$(m=0, 1, 2, \dots, n),$$

$$h_m(x,y,z) = \int_{-\pi}^{\pi}(z+ix\cos u+iy\sin u)^n\sin mu\ du$$

$$(m=1, 2, 3, \dots, n)$$

It will be proved later that these functions $g_m(x,y,z)$ and $h_m(x,y,z)$ are linearly independent, and so they form a set of $2n+1$ independent harmonics

The General Solution of Laplace's Equation.—It has just been seen that any harmonic of degree n may be expressed in the form

$$\sum_{m=0}^{n}a_mg_m(x,y,z)+\sum_{m=1}^{n}b_mh_m(x,y,z),$$

where a_m and b_m are constants If now, for brevity,

$$\sum_{m=0}^{n}a_m\cos mu+\sum_{m=1}^{n}b_m\sin mu$$

be called $\pi f_n(u)$, it follows that *any* harmonic of degree n is expressible in the form

$$\int_{-\pi}^{\pi}(z+ix\cos u+iy\sin u)^nf_n(u)du,$$

where $f_n(u)$ is a function of u, and, conversely, if $f_n(u)$ is an *arbitrary* function of u, it may be verified by substituting the expression in Laplace's equation that it is a harmonic of degree n

Next take *any* solution V of Laplace's equation and suppose it to be expansible in a convergent series of positive integral powers of x,y,z, group together all the terms of the same degree and replace each group of terms of the same degree n by an expression of the form

$$\int_{-\pi}^{\pi}(z+ix\cos u+iy\sin u)^n f_n(u)du;$$

it follows that

$$V=\sum_{n=0}^{\infty}\int_{-\pi}^{\pi}(z+ix\cos u+iy\sin u)^n f_n(u)\,du;$$

and this value of V is expressible in the form

$$V=\int_{-\pi}^{\pi}f(z+ix\cos u+iy\sin u,\ u)du,$$

where f denotes a function of the two arguments $z+ix\cos u+iy\sin u$ and u; and conversely if f denotes an arbitrary function of its two arguments, the expression on the right may be shown to satisfy Laplace's equation.

It is possible to remove the restriction concerning the possibility of expanding V as a series of positive integral powers of x,y,z; and hence *the general solution of Laplace's equation may be written in the form*

$$V=\int_{-\pi}^{\pi}f(z+ix\cos u+iy\sin u,\ u)du.$$

This solution was obtained by E. T. Whittaker in 1902; it may be compared with the solution of the equation

$$\frac{\partial^2 W}{\partial x^2}+\frac{\partial^2 W}{\partial y^2}=0,$$

(known as Laplace's two-dimensional equation) namely

$$W=f(x+iy)+g(x-iy)$$

where f and g denote arbitrary functions.

Zonal, Tesseral and Sectorial Harmonics.—The $2n+1$ harmonics of degree n which have been constructed take more simple forms when referred to polar co-ordinates; it is, in fact, possible to establish the expansion:

$$(z+ix\cos u+iy\sin u)^n = r^nP_n(\cos\theta)+2\sum_{m=1}^{n}\frac{n!\,i^m}{(n+m)!}r^nP_n^m(\cos\theta)$$

$(\cos m\phi\cos mu+\sin m\phi\sin mu)$ where $P_n(\cos\theta)$ depends on θ, but not on ϕ, and $P_n^m(\cos\theta)=\sin^m\theta\dfrac{d^mP_n(\cos\theta)}{d(\cos\theta)^m}$.

From the form of the above expansion, it is evident that $r^nP_n(\cos\theta)$ is identical with $\frac{1}{2}g_0(x,y,z)$ so that

$$P_n(\cos\theta)=\frac{1}{2\pi}\int_{-\pi}^{\pi}\{\cos\theta+i\sin\theta\cos(\phi-u)\}^n du,$$

it follows from the statement that $P_n(\cos\theta)$ is independent of ϕ that it is permissible to put $\phi=0$ in the last formula without affecting the result; and so

$$P_n(\cos\theta)=\frac{1}{2\pi}\int_{-\pi}^{\pi}(\cos\theta+i\sin\theta\cos u)^n du,$$

a formula known as *Laplace's integral*.

From the result stated, it follows that $2n+1$ harmonics of degree n are

$$r^nP_n(\cos\theta), r^nP_n^m(\cos\theta)\cos m\phi,\ r^nP_n^m(\cos\theta)\sin m\phi,$$
$$(m=1,2,\cdots,n),$$

and, from the manner in which ϕ occurs in them, they are obviously linearly independent.

An alternative definition of $P_n(\cos\theta)$ is derived from the fact that the potential produced at (x,y,z) by a unit mass at $(0,0,a)$ is

$$1/\sqrt{\{x^2+y^2+(a-z)^2\}}=1/\sqrt{(a^2-2ar\mu+r^2)},$$

in polar co-ordinates, where μ denotes $\cos\theta$; when this potential function is expanded in ascending powers of r, the result is of the form

$$\frac{1}{a}+\frac{rP_1(\mu)}{a^2}+\cdots+\frac{r^nP_n(\mu)}{a^{n+1}}+\cdots,$$

where $P_n(\mu)$ depends on μ and n only; and it may be seen from the expression in Cartesian co-ordinates that $r^nP_n(\mu)$ is a harmonic of degree n; it is possible to identify $P_n(\mu)$, defined in this manner, with Laplace's integral; and it can be proved that

$$P_1(\mu)=\mu,\quad P_2(\mu)=\frac{3\mu^2-1}{2},\quad P_3(\mu)=\frac{5\mu^3-3\mu}{2},\cdots,$$

$$P_n(\mu)=\frac{(2n)!}{2^n\cdot(n!)^2}\left[\mu^n-\frac{n(n-1)}{2(2n-1)}\mu^{n-2}+\frac{n(n-1)(n-2)(n-3)}{2\cdot4(2n-1)(2n-3)}\mu^{n-4}-\cdots\right].$$

If a sphere is drawn with centre at the origin, the locus of points on the sphere at which $P_n(\cos\theta)$ vanishes consists of the n parallels of latitude on which the cosine of the co-latitude is a root of the equation $P_n(\mu)=0$; the locus thus divides the sphere into $n+1$ zones, and for this reason $r^nP_n(\cos\theta)$ is called a *zonal* harmonic.

In like manner when $n>m\geqq1$, $P_n^m(\cos\theta)$ vanishes on $n-m$ parallels of latitude, while $\cos m\phi$ vanishes on $2m$ meridians, and $\sin m\phi$ vanishes on $2m$ other meridians; the sphere is thus divided into $2m(n-m-1)$ rectangular regions, with $2m$ triangular regions round each pole, and for this reason $r^nP_n^m(\cos\theta)\cos m\phi$ and $r^nP_n^m(\cos\theta)\sin m\phi$ are called *tesseral* harmonics (τέσσερα = a square).

For similar reasons $r^nP_n^n(\cos\theta)\cos n\phi$ and $r^nP_n^n(\cos\theta)\sin n\phi$ are called *sectorial* harmonics.

The function $P_n(\cos\theta)$ is called a *Legendre coefficient*, or a *Legendre function*, while $P_n^m(\cos\theta)$ is called an *associated Legendre function*.

Normal Solutions of Laplace's Equation.—The zonal, tesseral and sectorial harmonics are of the form $R\cdot\Theta\cdot\Phi$ where R,Θ,Φ respectively involve the co-ordinates, $r,\theta,\ \phi$, only; a solution consisting of the product of three functions each involving only one co-ordinate is called a *normal solution*.

Thus, if $X\cdot Y\cdot Z$ is a normal solution of Laplace's equation in Cartesian co-ordinates, it follows, on substitution and division by XYZ, that

$$\frac{1}{X}\frac{\partial^2X}{\partial x^2}+\frac{1}{Y}\frac{\partial^2Y}{\partial y^2}+\frac{1}{Z}\frac{\partial^2Z}{\partial z^2}=0,$$

and so $\quad\dfrac{1}{X}\dfrac{\partial^2X}{\partial x^2},\quad\dfrac{1}{Y}\dfrac{\partial^2Y}{\partial y^2},\quad\dfrac{1}{Z}\dfrac{\partial^2Z}{\partial z^2}$

must be respectively independent of x,y,z; hence they are constants. If these constants are called a^2, b^2, c^2, where $a^2+b^2+c^2=0$, we obtain the solutions

$$V=e^{\pm ax\pm by\pm cz}.$$

Similarly, if $R\Theta\Phi$ is a normal solution in polar co-ordinates,

$$\frac{1}{R}\frac{d}{dr}\left(r^2\frac{dR}{dr}\right)+\frac{1}{\Theta\sin\theta}\frac{d}{d\theta}\left(\sin\theta\frac{d\Theta}{d\theta}\right)+\frac{1}{\Phi\sin^2\theta}\frac{d^2\Phi}{d\phi^2}=0,$$

and so $\dfrac{1}{R}\dfrac{d}{dr}\left(r^2\dfrac{dR}{dr}\right)$ and $\dfrac{1}{\Phi}\dfrac{d^2\Phi}{d\phi^2}$ must be constants, say $n(n+1)$ and $-m^2$; and so Θ satisfies the equation

$$\frac{1}{\sin\theta}\frac{d}{d\theta}\left(\sin\theta\frac{d\Theta}{d\theta}\right)+\left(n[n+1]-\frac{m^2}{\sin^2\theta}\right)\Theta=0,$$

while $\quad\dfrac{d}{dr}\left(r^2\dfrac{dR}{dr}\right)-n(n+1)R=0,\quad\dfrac{d^2\Phi}{d\phi^2}+m^2\Phi=0.$

Possible values of R are r^n and r^{-n-1}; and possible values of Φ are $\cos m\phi$ and $\sin m\phi$. But now n and m are not necessarily integers, and so the question arises of defining $P_n^m(\cos\theta)$ in such circumstances.

This problem is dealt with by means of the hypergeometric function of Gauss defined by the equation

$$F(\alpha,\beta;\gamma;z)=1+\frac{\alpha\beta}{\gamma\cdot1}z+\frac{\alpha(\alpha+1)\beta(\beta+1)}{\gamma(\gamma+1)\cdot1\cdot2}z^2+\cdots.$$

A solution of the equation which it is convenient to adopt as the definition of $P_n^m(\cos\theta)$ is

$$P_n^m(\cos\theta) = \frac{1}{\Gamma(1-m)}\left(\frac{\mu+1}{\mu-1}\right)^{\frac{1}{2}m} F(-n,\, n+1,\, 1-m,\, \tfrac{1}{2}-\tfrac{1}{2}\mu),$$

where $\Gamma(1-m)$ denotes the gamma function of Euler which reduces to $(-m)!$ when m is a negative integer (when m is a positive integer, this function differs from the associated Legendre function, as previously defined, by a constant factor) The theory of generalized Legendre functions is consequently merged into the wider theory of hypergeometric functions

Cylindrical and Ellipsoidal Harmonics.—The cylindrical co-ordinates (ρ,ϕ,z) of a point are defined by the equations

$$x=\rho\cos\phi,\quad y=\rho\sin\phi,\quad z=z$$

When the solution $e^{k(z+ix\cos u+iy\sin u)}$ of Laplace's equation is expressed in terms of such co-ordinates it becomes:

$$e^{kz}e^{ik\rho\cos(\phi-u)}$$

and this can be expanded in the form

$$e^{kz}\left[J_0(k\rho)+2\sum_{m=1}^{\infty} i^m J_m(k\rho)\,(\cos m\phi\cos mu+\sin m\phi\sin mu)\right]$$

where $$J_m(k\rho) = \sum_{n=0}^{\infty} \frac{(-1)^n(\tfrac{1}{2}k\rho)^{m+2n}}{n!(m+n)!}$$

This leads to the consideration of the *cylindrical harmonics*

$$e^{kz}J_0(k\rho),\quad e^{kz}J_m(k\rho)\cos m\phi,\quad e^{kz}J_m(k\rho)\sin m\phi,$$

which may also be derived as normal solutions of Laplace's equation in cylindrical co-ordinates, viz.

$$\frac{1}{\rho}\,\frac{\partial}{\partial\rho}\left(\rho\frac{\partial V}{\partial\rho}\right)+\frac{1}{\rho^2}\,\frac{\partial^2 V}{\partial\phi^2}+\frac{\partial^2 V}{\partial z^2}=0$$

The functions $J_m(k\rho)$ are known as *Bessel functions* (*q v*) They occur in numerous physical problems of diverse types including F. W Bessel's investigations of planetary motion, Daniel Bernoulli's problem of a vibrating hanging chain and L Euler's problem of a vibrating circular membrane

The functions which occur in a similar manner when Laplace's equation is referred to a system of confocal conicoids as surfaces of reference are known as *Lamé's functions*, these are of a more complicated type than the functions described hitherto, because they cannot be expressed as series with simple coefficients But when the confocal conicoids are spheroids, the substitution

$$x=(r^2-c^2)^{\frac{1}{2}}\sin\theta\cos\phi,\quad y=(r^2-c^2)^{\frac{1}{2}}\sin\theta\sin\phi,\quad z=r\cos\theta$$

gives a form of Laplace's equation with normal solutions of the type

$$P_n^m(r/c)\,P_n^m(\cos\theta)\,{\cos \atop \sin}\, m\phi,$$

the spheroids being prolate, with oblate spheroids, c must be replaced by ic.

Recent Researches.—Some of the main lines along which progress has been made in recent years include methods of transforming the hypergeometric series, obtaining approximate expressions for $P_n^m(\cos\theta)$ when n or m (or both) is large, expanding arbitrary functions of two variables as series of surface harmonics, expanding arbitrary functions $f(\mu)$ in the form $\sum a_n P_n(\mu)$, obtaining approximate formulae for $J_n(z)$ when z or n (or both) is large; obtaining formulae by which the roots of the equation $J_n(z)=0$ may be calculated; expanding arbitrary functions as series of Bessel functions, obtaining integral equations satisfied by ellipsoidal harmonics, and by the harmonic functions associated with confocal elliptic cylinders. These investigations all arose in the first instance out of some problem of Mathematical Physics, though many of them require the most profound methods of Pure Mathematics for their solution.

SPHEROID, literally a sphere-like body In geometry the term is applied to figures generated by an ellipse (q v) revolving about either its minor axis (giving an *oblate spheroid*) or its major axis (giving a *prolate spheroid*) If the equation of the generating ellipse is $b^2x^2+a^2y^2=a^2b^2$, and the ellipse revolves about the major axis (the x axis), the volume is $\frac{4}{3}\times ab^2$, if about the minor axis, it is $\frac{4}{3}\pi a^2b$ The equation of the prolate spheroid is $b^2x^2+a^2(y^2+z^2)=a^2b^2$, and of the oblate spheroid it is $b^2(x^2+z^2)+a^2y^2=a^2b^2$. *See* Ellipsoid

SPHERULITES, in petrology, small rounded bodies which commonly occur in vitreous igneous rocks They are often visible in specimens of obsidian, pitchstone and rhyolite as globules about the size of millet seed, with a duller lustre than the surrounding glassy base of the rock, and when they are examined with a lens they prove to have a radiate fibrous structure Under the microscope the spherulites are of circular outline and composed of thin divergent fibres, which are crystalline and react on polarized light Between crossed nicols a black cross appears in the spherulite; its axes are usually perpendicular to one another and parallel to the crossed wires; as the stage is rotated the cross remains steady; between the black arms there are four bright sectors This shows that the spherulite consists of radiate doubly refracting fibres which have a straight extinction, the arms of the black cross correspond to those fibres which are extinguished The aggregate is too fine grained for us to determine its minerals

Spherulites are commonest in acid glassy rocks but occur also in basic glasses such as tachylyte Sometimes they compose the whole mass; more usually they are surrounded by a glassy or felsitic base When obsidians are devitrified the spherulites are often traceable, though they may be more or less completely re-crystallized or silicified In the centre of a spherulite there may be a crystal (*e g*, quartz or felspar) or sometimes a cavity Occasionally spherulites have zones of different colours, and while most frequently spherical they may be polygonal, or irregular in outline In some New Zealand rhyolites the spherulites send branching "cervicorn" processes (like stags' horns) outwards through the surrounding glass of the rock Long, elliptical or band-like spherulites are called *axiolites*

Spherulites may be ½in or more in diameter In composition they are a mixture of quartz and acid felspar

Very large and cavernous spherulites have been called *lithophysae;* they are found in obsidians at Lipari, the Yellowstone Park, etc The characteristic radiate fibrous structure is usually conspicuous, but the fibres are interrupted by cavities which are often so arranged as to give the spherulite a resemblance to a rosebud with folded petals separated by arching interspaces Some of these lithophysae are 1in or more in diameter In the crystallization of a glass there must be contraction, and it is supposed that thus the concentric cavities arise The steam and other vapours in the magma would fill these empty spaces and exert a powerful mineralizing action on the warm rock Analogous structures may be produced in artificial glasses, salt solutions and melts of organic substances (J S F)

SPHINX, the Greek name for a compound creature with lion's body and human head (Gr σφίγγειν to draw tight, squeeze) The Greek sphinx had wings and female bust, and the

male sphinx of Egypt (wingless) is distinguished as "androsphinx" by Herodotus. The type perhaps originated in Egypt, where a defined type is usually recumbent. The most celebrated example is the Great Sphinx of Giza, 189ft. long, a rock carved into this shape, and from its situation likely to be the work of the IVth Dynasty.

According to inscriptions of the XVIIIth Dynasty in the shrine between the paws, it represented the sun god Harmachis. It has recently been completely excavated and its head restored. Sphinxes of granite, etc., occur of the XIIth Dynasty and later. (*See* EGYPT, *Art and Archaeology.*) The heads of the sphinxes are royal portraits, and apparently they are intended to represent the power of the reigning Pharaoh. The king as a sphinx, in certain religious scenes, makes offerings to deities; and elsewhere he tears his enemies in pieces. Sphinxes in pairs guarded the approach to a temple, and the Great Sphinx at Giza so guards the entrance of the Nile valley.

The great temple avenues at Thebes are lined with recumbent rams, true sphinxes (a few late instances), and with the so-called criosphinxes or ram-sphinxes, having lion bodies and heads of the sacred animal of Ammon. A falcon-headed sphinx was dedicated to Harmachis in the temple of Abu Simbel, and is occasionally found in sculptures representing the king as Horus, or Mont, the war-god. It is distinguishable from the gryphon only by the absence of wings.

In Assyria the sphinx appears with a bearded male head on cylinders; the female sphinx, lying down and furnished with wings, is first found in the palace of Esar-haddon (7th cent. B.C.). Sphinxes have been found in Phoenicia, one at least being winged and another bearded. They are copies of the Egyptian, both in form and posture, wearing the pshent and the uraeus, but distinguished by having the Assyrian wings. The sphinx is common on Persian gems, and the representations are finely executed. On a Persian intaglio are two sphinxes face to face, each wearing a tiara and guarding a sacred plant which is seen between them; but the sphinx, whether of the Egyptian or the Assyrian type, is not found in Persian sculptures (Perrot and Chipiez, *History of Art in Persia,* Eng. trans., London, 1892). In Asia Minor the oldest examples are the "Hittite" sphinxes of Euyuk. They are Egyptian sphinxes treated in the Assyrian style. They are not recumbent, and the hair falling from the head is curled, not straight, as in the true Egyptian sphinx.

In the early art of Cyprus (the half-way house between Asia and Greece) sphinxes of Greek type are not uncommon. On the other hand, on a gem of Phoenician style found at Curium in Cyprus there appear two male (bearded) sphinxes, with the tree of life between them. With regard to Greece proper, in the third tomb on the acropolis of Mycenae (*c.* 1600 B.C.) were found six small golden sphinxes; they are beardless, but the sex is doubtful.

Moreover, the sphinx (generally sejant, in the Greek fashion) was well-known in Minoan art. It occurs in ivory (couchant) among the Mycenean antiquities from Enkomi in Cyprus, in the British Museum. In the ancient tomb discovered in 1877 at Spata near Athens (which represents a kindred but somewhat later art than the tombs at Mycenae) were found female winged sphinxes carved in ivory or bone. Sphinxes on glass plates have been found in graves at Camirus in Rhodes and on gold plates in Crimean graves. Sphinxes were represented on the throne of Apollo at Amyclae and on the metopes at Selinus; in the best period of Greek art a sphinx was sculptured on the helmet of the statue of Athena in the Parthenon at Athens; and sphinxes carrying off children were sculptured on the front feet of the throne of Zeus at Olympia. There have been found in Boeotia terra-cotta figures of wingless sphinxes. Roman sphinxes of a late period have sometimes a man's, sometimes a woman's head with an asp on the forehead.

In Greek mythology the most famous sphinx was that of Thebes in Boeotia, first mentioned by Hesiod (*Theog.* 326), who calls her the daughter of Orthus and Chimaera. According to Apollonius (iii. 5, 8), she was the daughter of Typhon and Echidna, and had the face of a woman, the feet and tail of a lion and the wings of a bird. She dwelt at the south-east corner of Lake Copais on a bald rocky mountain called Phicium (mod. Fagas), which was derived from Φίξ, the Aeolic form of σφιγξ. The Muses taught her a riddle and the Thebans had to guess it. Whenever they failed she carried one of them off and devoured him. The riddle was this: "What is that which is four-footed, three-footed and two-footed?" At last Oedipus guessed correctly that it was man; for the child crawls on hands and feet, the adult walks upright, and the old man supports his steps with a stick. Then the sphinx threw herself down from the mountain.

Among the remains of the Mayan culture in Yucatan are found examples of sphinxes, male and female, which are not unlike those of Egypt and Asia Minor.

SPICE-BUSH (*Benzoin aestivale*), a North American shrub of the laurel family (Lauraceae), allied to the sassafras and Oregon myrtle (*qq.v.*), native to moist woods from Massachusetts to Ontario and Michigan south to North Carolina and Kansas. It grows from 4 to 20 ft. high, with smooth fragrant twigs and foliage, and bears bright yellow flowers, which unfold before the leaves, and scarlet fruit (drupe), maturing in late summer. The similar hairy spice-bush (*B. melissaefolium*) is found in swamps in the south-eastern States. The bark of *B. aestivale* was formerly of high repute in household medicine, being used as a febrifuge.

SPIDER-MONKEY, a group of tropical American monkeys known to zoologists as *Ateles.* They take their English name from the slimness of the body, the elongated limbs, and the long tail, the under surface of the prehensile extremity of which is naked. The thumb is rudimentary or wanting. The absence of woolly under-fur, and the broader partition between the nostrils distinguishes them from the woolly spider-monkeys (*Brachyteles*). The species are arboreal. (*See* PRIMATES.)

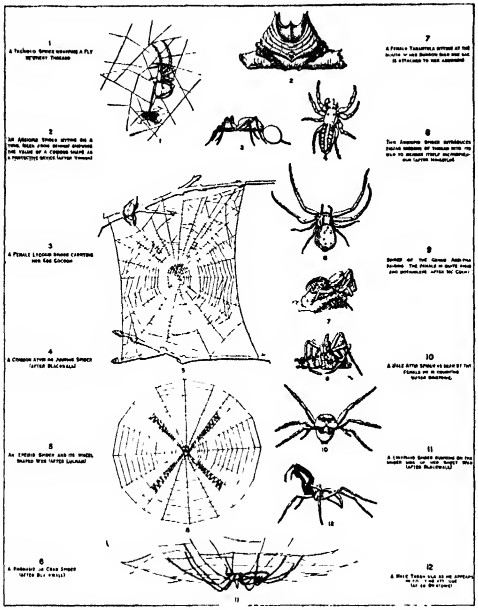
SPIDERS are a group of animals closely related to scorpions, mites and harvestmen belonging like them to the natural class Arachnida (*q.v.*) but being characterized within it by possessing silk-producing organs called spinnerets, which are attached to the underside of the abdomen. A good many other Articulata can produce silk, but none make such an extended and diversified use of it as spiders. They employ it not only for making cocoons to protect both the eggs and the spiders themselves, young and mature, from wet and cold, but they also weave it into snares as beautiful as they are diabolical in their ingenuity.

Besides their silk, spiders have another weapon of offence in poison, which they inject into their prey through the sharp sickle-shaped digital joints of their front jaws. Cases are known of spider-poison affecting vertebrate animals and being fatal to man, but it is far quicker in its action on the spiders' natural prey, the articulate animals, where it induces rapid paralysis.

Many spiders, although able to produce silk, spin no web, but rely on a fairly keen sense of sight for catching insects. Such are the *Salticidae* or jumping spiders, which stalk their prey stealthily and leap upon it when close enough. These have relatively large eyes and, as they are diurnal in their habits and love to run and jump in the sunshine, many of them are coloured in such a way as to render them inconspicuous among their surroundings, while a few closely resemble certain species of ants and thus escape the attention of many of their natural enemies. The *Thomisidae* are called "crab-spiders," since many run sideways. One Thomisid, *Misumena vatia* is light green or yellow and lurks in yellow or white flowers.

The *Lycosidae,* another family of wandering spiders, are not so long-sighted as the *Salticidae* and only attack when an insect comes close or touches them. Some of them have developed

more sedentary habits, probably owing to the continual attacks of various solitary wasps which paralyse the spiders with their stings and store them living in their nests to be food for their larvae when they hatch out. The famous Tarantulas (*q.v.*) build silk-lined burrows in sandy soil, and often construct a little parapet or a trap-door at the opening. Here they sit waiting until an insect comes within striking distance. One little Lycosid, *Trochosa*



TYPES OF SPIDERS, VENOMOUS AND NON-VENOMOUS
(1) Theridiid spider, wrapping a fly in sticky threads; (2) Argiopid spider, shown from behind (After Vinson); (3) Female Lycosid spider carrying egg cocoon; (4) Common Attid spider (After Blackwall); (5) Epeirid spider and web (After Lulham); (6) Thomasid spider (After Blackwall); (7) Female Tarantula with egg sac attached to abdomen; (8) Argiopid spider (After Hingston); (9) Grass spider (*Agalena*), pairing (After McCook); (10) Male Attid spider (After Bristowe); (11) Linyphid spider, on under side of her sheet web (After Blackwall); (12) Male Tarantula, in courting attitude (After Bristowe)

picta, besides having a burrow for protection, is spotted with black, yellow, pink and white, so that while it is motionless on sandy soil it is often quite invisible Burrowing habits are also found among the *Mygalomorphae,* a group differing widely from *Lycosidae,* and including the large "bird-eating" spiders. They are much more skilful builders, the trap doors which some of them make being beautiful close-fitting structures, decorated with *débris,* indistinguishable from their surroundings.

Some *Lycosidae* of the genus *Pirata* live by water, on which they can run perfectly. Moreover, they can submerge themselves when necessary by climbing down stems of water-plants, taking down as air supply a bubble, entangled in the hairs of the body, which will last for many hours *Lycosa purbeckensis,* which lives on marshy ground among tussocks of grass and reeds by tidal estuaries, runs over the water to a plant stem as the tide comes in and deliberately crawls down, remaining submerged until the ebb. In a closely related family, the *Agalenidae,* is placed the water-spider, *Argyroneta aquatica,* which leads a truly aquatic life. It builds a little silken diving bell under the water and fills it with air carried down as bubbles between the abdomen and back legs. Its food consists of aquatic insects, and it even mates and produces its young in its nest under water Other species of the genus *Desis* live in the sea and make nests in coral reefs below high water mark, coming out at low tide to prey on small crustaceans. Among other genera in the same family are land-dwellers with a much more highly developed web, on which the spiders depend for the capture of prey The upper end of the silken tube, used as a retreat, opens out into a wide sheet of which the cobwebs built in the angles of walls by various species of *Tegenaria* are examples When an insect falls on to the sheet the spider rushes out, seizes it in its jaws and rushes back to its retreat. The attack is very simple, the web serving to guide the spider to its prey.

The *Theridiidae* are an interesting family of spiders which are usually globular-bodied with relatively long legs and small jaws. They build somewhat formless snares consisting of single threads spun at random in a criss-cross manner. When a fly becomes entangled in the web, the spider runs out, turns round and covers its victim with sticky threads which it draws out of its spinnerets with its two back legs Then approaching very carefully, it bites a projecting leg or wing, whereupon the insect's struggles slacken and soon cease owing to paralysis produced by the spider's poison. If the first bite is not effective another is administered after more silk has been thrown on The silk has here a more complicated function. For whereas the *Agalena* or *Tegenaria* relies on the strength of her limbs and jaws and the *Linyphia* on the protection of her sheet, rushing straight at her prey, the *Theridion* with her feeble jaws must restrict her prey's violent struggles before she can safely approach.

Many species of the *Argiopidae* spin the most strikingly regular and beautiful wheel-shaped webs. The stages of the construction of these webs are always the same A triangular or trapezoid framework attached to plants or near-by objects is first laid down Then the radii of the wheel are made, all equidistant and converging to a silken hub or platform. Next a temporary spiral is woven to act as a bridge for the construction of the final spiral, which is made of sticky threads. The spiral is begun on the outer margin of the web, and, one round completed, the spider walks to the next radius and feels with the tip of its fore leg until it touches the filament of the spiral laid down in its previous circuit When this is done the spinnerets are applied to the radius and the attachment made Then spinning, it proceeds to the next radius, feels for the outer circuit, again attaches its thread, and so continues, with the result that each turn of the spiral is at a fixed distance from the turns on either side of it. If the spider's fore leg be amputated, the measuring is at once at fault and the snare when made is quite irregular

When an insect becomes entangled in a wheel web, the spider runs towards it and bites it, then wraps it in silk and carries it to the platform or to its retreat to eat A large and formidable insect, however, is made to revolve and serve as a bobbin, becoming enwrapped at once in a dense sheet, so that the spider can approach and bite it Some of these spiders which sit in the middle of their webs are exposed to the attacks of birds, as well as of solitary wasps and ichneumons which lay their eggs on the living spiders There is in Brazil a predaceous fly which attacks and eats the spiders as they sit in their webs Many species, then, are protected by the most ingenious devices Some are specially coloured *Epeira cucurbitina,* which builds its web on leaves, is bright green Others spin in their webs silk bands, zig-zags or crosses and take up such positions that they seem to form part of these devices Sometimes insect débris is made with silk into pellets which closely resemble the spider, or sometimes cocoons have the same function

A large group of spiders have an auxiliary spinning organ called a "cribellum," which produces a very fine flocculent silk which the spider draws out in tiny waves by means of a comb of stiff bristles (the calamistrum) attached to the hind legs The spider bites either the body or the limb of its entangled prey, and then simply holds on The poison is usually powerful.

Courtship and Mating.—The courtship and mating of spiders, which is often extremely curious, presents some very interesting problems. The male can be instantly recognized as such by dark swellings on the digital joints of the palpi. These are produced by organs which are used for conveying the sperms to the female The testes lie in the abdomen, and the male before

mating deposits a drop of sperm on to a sheet or strand of silk, then reabsorbs it into the palpal organs, which are applied to the female's epigynum (underneath the abdomen) during mating.

Courtship serves one or both of two functions, recognition and stimulation. The female spends her life capturing and eating in order to grow and provide substance for her eggs. Another spider, even of the same species is as good food as any other, and unless the male advertised his identity he might well be attacked and eaten before mating could take place. Males of the families *Salticidae* and *Lycosidae,* keen-sighted spiders, have often curious little tufts of coloured or dark hairs on their legs, palpi or the fore parts of their bodies. These epigamic characters they display in ludicrous dances before their prospective mates. Once the males have started dancing, they are comparatively safe, but they must continue, often for hours, until the females are so stimulated that they will submit to mating. In *Pisaura mirabilis,* of a closely related family, *Pisauridae,* the male has no epigamic characters, but approaches his mate with a fly, wrapped in silk, which she seizes and retains during mating.

The web-spinning spiders even if they see distinctly do not rely on sight to any appreciable extent. These males perform a tactile courtship through the medium of the web. As a rule the female recognizes the male's movements at once, and his courtship, a series of pluckings or jerks on the web, now serves to stimulate her and to entice her out from her retreat to a clear space where mating can take place.

As the season proceeds females of short-lived spiders usually lose much of their sexual impulse and are concerned solely with feeding and later with egg-laying. Males, their purpose served, are no longer recognized, and are often attacked and eaten.

Cocoons and Young.—All spiders make silken cocoons for their eggs, a fact which suggests that this was the first function of the silk. But in spite of the protection thus provided, the eggs are often infested with the larvae of parasitic Ichneumons and Diptera which eat them before they are hatched.

The *Lycosidae* carry their egg-cocoons attached with silk to their spinners and are very concerned if one tries to remove them, resisting furiously. But if they are given some other object of about the same size as the cocoon, such as a pith ball, they will accept it even though it be brightly coloured! Some tarantulas sit in the sun at the mouths of their burrows turning their cocoons slowly so that they receive light and warmth.

As soon as the young hatch, they scramble on to their mother's back and (as with all *Lycosidae*) cling on to her abdomen and are carried about for several weeks before they disperse.

Each minute spider climbs above its nest and then emits silk which is caught and drawn out by the wind. When the strand is long enough the spider seizes it with its legs and is borne away on the wind, often for a great distance. Such gossamer threads are a very beautiful sight on still days in autumn when they often cover whole fields.

In spite of their ingenuity shown in the construction of webs, burrows and nests of all kinds, spiders appear to have practically no intelligence. All their actions are instinctive. Even the construction of the beautiful wheel webs is quite automatic, the severing of one strand of the spiral producing a corresponding deformity in the next. The Lycosid will accept a pith ball instead of her egg-cocoon, and a Theridion will industriously enwrap a piece of paper agitated with a needle point. (For classification of spiders, *see* ARACHNIDA.) (G. H. L.)

SPIELHAGEN, FRIEDRICH VON (1829–1911), German novelist, was born at Magdeburg on Feb. 24, 1829. He was brought up at Stralsund, studying also at Berlin, Bonn and Greifswald. He became a master in a gymnasium at Leipzig, but upon his father's death in 1854 devoted himself entirely to writing. After publishing *Klara Vere* (1857) and *Auf der Düne* (1858), he obtained a striking success with *Problematische Naturen* (1860–1861). His powerful *Sturmflut* appeared in 1876. He died Feb. 25, 1911.

Spielhagen's *Sämtliche Werke* were published in 1871 in sixteen volumes, in 1878 in fourteen volumes; his *Sämtliche Romane* in 1898 (22 vols.), and these were followed by a new series in 1902. *See* his autobiography, *Finder und Erfinder* (2 vols., 1890).

SPIKENARD or **NARD,** a celebrated perfume which seems to have formed one of the most durable aromatic ingredients in the costly unguents used by the Romans and Eastern nations. The ointment prepared from it is mentioned in the New Testament (Mark xiv. 3–5; John xii. 3–5) as being "very costly," a pound of it being valued at more than 300 denarii (over £10). This appears to represent the prices then current for the best quality of nard, since Pliny (*H.N.* xii. 26) mentions that nard spikes reached as much as 100 denarii per lb. The source of the true or Indian nard is now identified as *Nardostachys jatamansi,* a plant of the family Valerianaceae, the fibrous root-stocks or "spikes" of which are still collected in Bhotan and Nepal.

The great spikenard of the United States is *Aralia racemosa,* and another species of the same genus, *A. nudicaulis,* or wild sarsaparilla, is known as "wild spikenard." In the West Indies *Hyptis suaveolens* is called "spikenard," and in Great Britain the name "ploughman's spikenard" is given to *Inula squarrosa* (*I. conyza*).

SPILITE, in petrology, a rock of basaltic character, but possessing in place of the normal labradorite, a felspar of the composition of albite. The ferromagnesian mineral is an augite of pale brown colour; spilites are, however, usually very completely decomposed, augite being represented by chlorite and calcite. They are commonly vesicular or variolitic and show wonderfuly preserved pillow structure, a feature in most cases indicative of a submarine origin of the lavas. The individual pillows are filled with concentric zones of vesicles filled with chlorite and calcite. The formation of pillow structure in volcanic rocks has been directly observed by Dr. Tempest Anderson in the case of the lava poured into the sea from the volcano Matavanu, in Samoa. On the surface of the lava, buds form and expand, giving rise to "pillows" with a glassy crust. The interspaces between the pillows are frequently filled with sediment representing the soft ooze of the sea floor. Not all pillow lavas are spilitic in character.

Some spilites showing pillow structure are not strictly lavas but shallow intrusions into unconsolidated submarine ooze. Excellent examples of such intrusive spilites are provided by the Devonian spilites of Nundle, New South Wales. Though the term spilite was first used by Brongniart for altered basic lavas free from phenocrysts and possessing well marked vesicular textures, a new significance was given to the term by Dewey and Flett, who urged that a special group of rocks—the spilitic suite—should be recognized. According to these authors, a large suite of igneous rocks is genetically associated with the spilites. Their composition varies widely, but they all have some characters in common. They possess a high percentage of soda and are usually extensively altered. These rocks are albite-dolerites, minverites, picrites, keratophyres, soda-felsites and soda-granites. The spilitic suite was originally given a status comparable with that of the alkaline and calc-alkaline suites. The spilitic series is regarded as peculiar to districts that have undergone a long continued and gentle subsidence with few or slight upward movements and no important faulting. The lavas are poured out on the margins of geosynclines while their common sedimentary associates are black shales, limestones and radiolarian cherts. As geosynclines are the centres of subsequent fold movements many ancient spilites have become extensively folded and metamorphosed with production of new minerals, including albite of metamorphic origin. Eruptions having the spilitic facies have occurred repeatedly over a wide area and on a large scale. The analyses of average basalt and spilite are as follows:

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	Na_2O	K_2O	$H_2O(+)$	TiO_2	CO_2
Average basalt	49·06	15·70	5·38	6·37	6·17	8·95	3·11	1·52	1·62	1·36	..
Average spilite	46·01	15·21	1·35	8·69	4·18	8·64	4·97	0·34	2·48	2·21	4·98

(C. E. T.)

SPINA, an ancient city of Gallia Cispadana, Italy, between Ravenna and the mouths of the Po. In Etruscan times it was the

principal port of Felsina. (*See* BONONIA.) Near Comacchio, in the draining of the lagoon of Valle Trebba, a very extensive necropolis has been found and some 450 tombs have been excavated, ranging from the 6th to the 3rd century B C. They contained fine Greek, Italic and Etruscan vases.

SPINACH (*Spinacia oleracea*), an annual plant, a member of the family Chenopodiaceae, which has been long cultivated for the sake of its succulent leaves. It is probably of Persian origin, being introduced into Europe about the 15th century It should be grown on good ground, well worked and well manured, and for the summer crops abundant watering will be necessary. (*See* VEGETABLE.)

SPINAL COLUMN, SURGERY OF. Most operations on the vertebral column are designed to relieve some condition of the enclosed spinal cord. The essentially degenerative diseases (tabes dorsalis, disseminated sclerosis, etc) offer little scope for surgery, which finds its richest field in cases of cord compression. Spina bifida, a congenital defect in development, calls for operation in selected cases only, for most sufferers from this condition die during the first weeks or months of life

There is one fundamental fact which we must grasp if we wish to understand the possibilities of spinal surgery. that regeneration is impossible, so that once the cord, and the long conduction tracts of which it is composed, suffers actual anatomical damage, that damage is permanent and cannot be undone It is, therefore, useless to operate if it is certain that the cord has actually been lacerated, or has been so long and so severely compressed that return of function is unlikely or impossible.

Spinal Injuries.—These are generally due to indirect violence, the fracture occurring at a point distant from that at which the force was applied Thus most injuries of the cervical spine (neck) are due to injuries applied to the head, whilst forcible flexion of the trunk by a weight falling on the shoulders (the common mechanism in pit accidents from a fall of "roof" or "dirt") causes a fracture at the first lumbar vertebra The 24 bones which make up the cervical, thoracic and lumbar spine are not equally prone to injury; the three predominant sites where fractures or dislocations occur are at the points where the qualities and range of movement change—at the second cervical, where the compound movements of the head change over into the ordinary movements of the neck, at the disc between the fifth and sixth cervical where the cervical mobility changes into the relative fixity of the chest, and at the first lumbar where the latter joins the rod-like lumbar portion The bodies of the vertebrae can be compressed or broken without injury to the spinal cord (so-called "Kummells' disease") provided there is no sliding of the broken parts on one another A fact which colours our whole attitude towards spinal injury to-day is that when the cord is damaged the lesion is inflicted at the moment of injury The old teaching was that the cord was being compressed by bone fragments and hence early operation was advised To-day we treat these cases with conservatism, reduce fractures by manipulation, and operate only when deterioration is setting in or pain is severe But operation is never done as an immediate urgency. X-Rays are of the greatest help In summary, the cord lesion associated with most injuries is central haemorrhage or actual laceration, and operation will not often be of service in the worst cases.

Spinal Tumours.—Once the diagnosis is reasonably certain it is best to operate early, for these growths are commonly (Elsberg gives 82%) outside the cord and can be dislodged by laminectomy. An incision is made over the spinous processes, the laminae are exposed by clearing the muscles with a rongeur and some three of them are removed. The dura mater is incised, if the tumour has not already been found outside The results in many cases are dramatic and the palsied may indeed be made to walk upright. When the tumour lies in the cord tissue, nothing of great service can be achieved. Deep X-Ray therapy is the only hope for such conditions, but only a few successes have so far been recorded. Little noticeable weakness follows a laminectomy *per se*.

Spinal Caries.—Tuberculosis of the vertebral column is commonest in the very young, and gives good results by fixation on frames or in plaster jackets Long periods of recumbency (1–3 years) are generally required In order to render sufferers ambulant at an earlier time, bone-grafting operations have been devised Albee advised this so-called "internal splinting" and recommended that a long thick graft should be taken from the tibia and inserted into a bed prepared for it over the bared spinous processes and laminae at the region affected, including two healthy vertebrae above and below Hibbs later introduced the operation of "spinal fusion"; in this no new bone is implanted but the spinous processes and laminae are split and turned up and down to produce a mass of bone which will lock the bones together The operations are most useful in persons of less tender years than are the majority of sufferers from Pott's disease In Great Britain and Europe generally, excellent results are obtained by less drastic means, but in those who cannot afford a long convalescence these operations should be considered

Sometimes a tuberculous abscess forms within the neural canal, extends backwards from the diseased vertebrae, and presses on the cord Happily most of these patients recover the function of their limbs when perfectly immobilised, laminectomy does not give the good results which one might theoretically expect from it

Pain.—Much can be done for sufferers from agonising pain by judicious spinal surgery. The chief indications for operation are neuralgia of the body or limbs, often the sequelae of amputations or of herpes zoster, the agonising pains of spinal syphilis, and hopeless malignant growths The usual operation heretofore has been section of posterior nerve roots just before they enter the spinal cord The exposure is the same as for spinal tumours The results of root sections have been inconsistent, and the operation is being replaced by section of the pain-carrying fibres in the cord itself (Spiller) This tract is the anterior spino-thalamic and lies just sufficiently far away from the motor pathway to the limbs (pyramidal tract) for its division to be effected without inflicting paralysis on the sufferer As the pain fibres cross in the cord, the tract of the opposite side to that on which the pain is felt is the one to be cut, and of course at a point cephalad to the site of the pain A cut 2·5 to 3·0mm deep is made into the antero-lateral aspect of the cord A very fine and sharp knife is required and the operation must be most delicately and precisely performed. Brilliant results have generally followed, but it is too early to say what the late effects are.

Spinal Puncture.—No account of modern spinal surgery can omit some reference to the extended usefulness which is being made of lumbar puncture (puncture into the subarachnoid space and withdrawal of a specimen of cerebro-spinal fluid) Our knowledge of the changing chemistry of that fluid in disease conditions is still growing When a tumour or the like grows in relation to the spinal cord it causes a block in the subarachnoid space, either by its own bulk or by compressing the membranes against one another should it be extra-dural The cerebro-spinal fluid distal (caudal) to the obstruction is dammed back, for it is chiefly absorbed within the skull and thither it can not now return A rise in albuminous content and a yellow tinge, xanthochromatosis (Froin's syndrome), are the results. This is of great diagnostic importance Queckenstedt's test also makes use of the block, for when a normal person's jugular veins are compressed the consequent rise of intracranial venous pressure is transmitted to the cerebro-spinal fluid as a whole and can be measured by a manometer attached to a lumbar-puncture needle If a tumour blocks the spinal canal the manometer records no change or modified changes only. This is most valuable in differentiating between the degenerative and compression groups of paralysis of the lower limbs. Lastly, Lipiodol, a heavy, opaque substance which when introduced into the cerebro-spinal fluid above the tumour sinks down through it to rest on the tumour, is proving most useful It is a 40% solution of inert iodine in poppy-seed oil and is quite opaque to X-Rays so that the precise position and often the shape of the upper end of the tumour becomes definitely recognisable

SPINAL CORD, in anatomy, that part of the central nervous system in man which lies in the spinal canal formed by the vertebrae, and reaches from the foramen magnum to the lower margin of the first lumbar vertebra. It is about 18in. long, and only occupies the upper two-thirds of the spinal canal. The cord is protected by the same three membranes which surround the brain. Outside is the *dura mater,* which differs from that of the brain in not forming a periosteum to the bones, in sending no processes inward, and in having no blood sinuses enclosed within its walls; it is the continuation of only the inner layer of the dura mater of the skull. Inside the dura mater is the *arachnoid,* which is delicate and transparent, while between the two lies the *subdural space,* which reaches down to the second or third sacral vertebra. The *pia mater* is the innermost covering, and is closely applied to the surface of the cord into the substance of which it sends processes. Between it and the arachnoid is the *sub-arachnoid space,* which contains the cerebro-spinal fluid. Across this space, on each side of the cord, run a series of processes of the pia mater arranged like the teeth of a saw; by their apices they are attached to the dura mater, while their bases are continuous with the pia mater surrounding the cord. These ligaments, each consisting of twenty-one teeth, are the *ligamenta denticulata,* and by them the spinal cord is moored in the middle of the cerebro-spinal fluid.

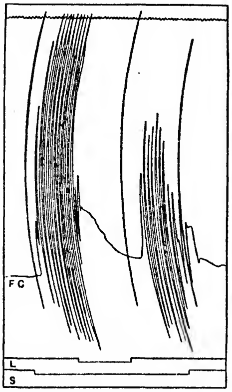

FIG. 1.—SPINAL CORD, SHOWING TRACINGS OF ANTAGONISTIC REFLEXES

The spinal cord itself is a cylinder slightly flattened from before backward. In the cervical region it is enlarged where the nerves forming the *brachial plexus* come off, while opposite the lower thoracic vertebrae the lumbar enlargement marks the region whence the lumbo-sacral nerves are derived. (*See* fig. 2.) Opposite the second lumbar vertebra the cylindrical cord becomes pointed and forms the *conus medullaris,* from the apex of which a glistening membranous thread runs down among the nerves which form the *cauda equina,* and, after blending with the termination of the dural sheath, is attached to the back of the coccyx.

Details of Structure.—In a transverse section of the cord (*see* fig. 3) two median fissures are seen; the antero-median is wide, and reaches about a third of the way along the antero-posterior diameter of the cord; it is lined by the pia mater and, in front, lies the single anterior spinal artery.

The postero-median fissure is much deeper and narrower, and has no reflection of the pia mater into it. Where the posterior nerve roots emerge is a depression which is called the *postero-lateral fissure,* while between this and the postero-median a slight groove is seen in the cervical region, the paramedian fissure (*see* also fig. 2). The anterior nerve roots do not emerge from a definite fissure.

The spinal cord, like the brain, consists of grey and white matter, but, as there is here no representative of the cortical grey matter of the brain, the white matter entirely surrounds the grey. In section the grey matter has the form of an H, the cross bar forming the grey *commissure.* In the middle of this the *central canal* can just be made out by the naked eye (*see* fig. 4). The anterior limbs of the H form the *anterior* or *ventral cornua,* while the posterior, which in the greater part of the cord are longer and thinner, are the *posterior* or *dorsal cornua.* At the tips of the latter is a lighter-coloured cap known as the *substantia gelatinosa Rolandi.* On each side of the H is a slighter projection, the *lateral cornu,* best marked in the thoracic region (*see* fig. 4).

The grey matter has different appearances in different regions of the cord, and in the cervical and lumbar enlargements, where the nerves to the limbs come off, the anterior horns are broadened (*see* fig. 4).

Histologically the grey matter is made up of neuroglia, medullated and non-medullated nerve fibres, and nerve cells (*see* NERVOUS SYSTEM). The nerve cells are arranged in three main columns, ventral, intermedio-lateral and posterior vesicular. The *ventral cell column* has the longest cells, and these are again subdivided into antero-mesial, antero-lateral, postero-lateral and central groups. The *intermedio-lateral cell column* is found in the lateral horn of the thoracic region.

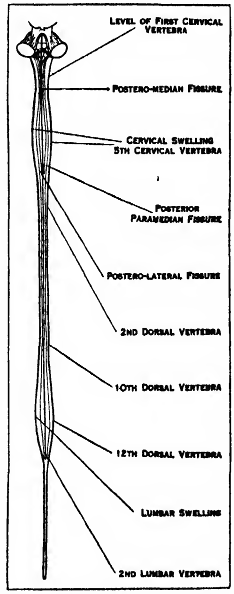

FIG. 2.—DIAGRAM OF DORSAL ASPECT OF SPINAL CORD, SHOWING CERVICAL AND LUMBAR SWELLINGS

The *posterior vesicular* or *Clarke's column* is also largely confined to the thoracic region, and lies in the mesial part of the posterior cornu. It is the place to which the sensory fibres of the sympathetic system (visceral afferents) run. The white matter, as has been shown, surrounds the grey and passes across the middle line to form the *white commissure,* which lies in front of the grey. It is composed of neuroglia and medullated nerve fibres, which are arranged in definite tracts, although in a section of a healthy cord these tracts cannot be distinguished even with the microscope. They have been and are still being gradually mapped out by pathologists, physiologists and embryologists.

A sensory nerve on passing into the cord (fig. 3) through the posterior nerve root lies close to the mesial side of the posterior horn of grey matter, where most of it runs upward. The next root higher up takes the same position and pushes the former one toward the middle line, so that the lower nerve fibres occupy an area close to the postero-median fissure known as the *tract of Goll,* while the higher lie more externally in the *tract of Burdach.* The greater part of each nerve sooner or later enters the grey matter and comes into close relation with the cells of Clarke's column, but some fibres run right up to the nucleus gracilis and cuneatus in the medulla (*see* BRAIN), while a few turn down and form a descending tract, which, in the upper part of the cord, is situated in the inner part of the tract of Burdach and is known as the *comma tract,* but lower down gradually shifts quite close to the postero-median fissure and forms the oval area of Flechsig. It will be obvious that both these tracts could not be seen in the same section, and that fig. 3 is only a diagrammatic outline of their position.

A few fibres of each sensory nerve ascend in a small area known as *Lissauer's tract* on the outer side of the posterior nerve roots, and eventually enter the substantia gelatinosa.

To the outer side of Lissauer's tract and lying close to the lateral surface of the cord is the *direct cerebellar tract,* the fibres of which ascend from the cells of Clarke's column to the cerebellum. As Clarke's column is only well developed in the thoracic region this tract obviously cannot go much lower.

In front of the last and also close to the lateral surface of the cord is another ascending tract, the *tract of Gowers,* or, as it is

sometimes called, the lateral sensory fasciculus. It probably begins in the cells of the posterior horn, and runs up to join the fillet and also to reach the cerebellum through the superior cerebellar peduncle. The *crossed pyramidal tract* lies internal to the direct cerebellar tract, between it and the posterior cornu. It is the great motor tract by which the fibres coming from the Rolandic area of the cerebral cortex are brought into touch with the motor cells in

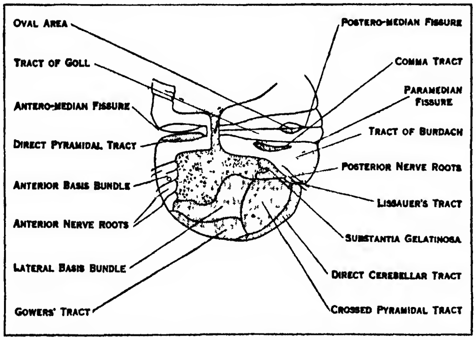

FIG 3—TRANSVERSE SECTION OF CORD SHOWING TWO MEDIAN FISSURES AND SCHEMATIC ARRANGEMENT OF COLUMNS OF FIBRES IN THE WHITE MATTER OF ONE HALF

the anterior cornu of the opposite side This tract extends right down to the fourth sacral nerve

In front of the crossed pyramidal tract is the lateral basis bundle, which probably consists of association fibres linking up different segments of the cord

The *anterior basis bundle* lies in front and on the mesial side of the anterior cornu, and through it pass the anterior nerve roots. Like the lateral bundle it consists chiefly of association fibres, but it is continued up into the medulla as the posterior longitudinal bundle to the optic nuclei

The *direct pyramidal tract* is a small bundle of the motor fibres from the Rolandic area, which, instead of crossing to the other side at the decussation of the pyramids in the medulla, runs down by the side of the antero-median fissure. Its fibres, however, keep on gradually crossing to the opposite side through the anterior white commissure of the cord, and by the time the mid-thoracic region is reached it has usually disappeared.

The roots of the spinal nerves in the upper part of the canal rise from the cord nearly opposite the points at which they emerge between the vertebrae, but the farther one passes down the higher the origin of each root becomes above its point of emergence Consequently the lumbar and sacral nerves run a long way down from the lumbar enlargement to their spinal foramina and are enclosed in the dural and arachnoid sheaths to form a mass like a horse's tail, which is therefore known as the *cauda equina*.

Embryology.—The early development of the neural tube from the ectoderm is outlined in the article on the BRAIN. When the neural groove becomes a tube it is oval in section with a very large laterally compressed central canal (*see* fig 5). The original ectodermal cells elongate and, radiating outward from the canal, are now known as spongioblasts, while the inner ends of some of them bear cilia and so the canal becomes ciliated A number of round cells, known as germinal cells, now appear close to the central canal, except at the thin mid-dorsal and mid-ventral laminae (roof-plate and floor-plate). From the division of these the primitive nerve cells or neuroblasts are formed and these later on migrate from the region of the canal and shoot out long processes—the axons. The permanent central canal of the cord was formerly said only to represent the ventral end of the large embryonic canal, the dorsal part being converted into a slit by the gradual closing in of its lateral walls, thus forming the postero-median fissure. A. Robinson, however, does not believe that the posterior fissure is any remnant of the central canal (*Studies in Anatomy*, Owens College, 1891). Probably the fissure is formed partly by an infolding and partly from the original central canal. The antero-median fissure is caused by the ventral part of the cord growing on each side, but not in the mid-line where no germinal cells are.

The anterior nerve roots are formed by the axons of the neuroblasts in the developing anterior cornua, but the posterior grow

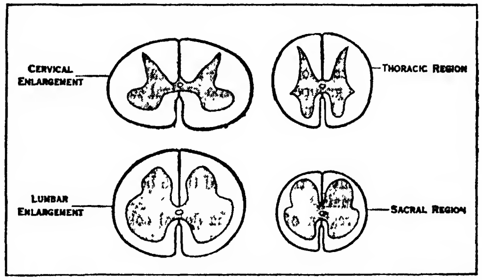

FIG 4.—SECTIONS OF SPINAL CORD AT DIFFERENT LEVELS (2 X NAT SIZE)

into the cord from the posterior root ganglia (*see* NERVE: *Spinal*), and, as they grow, form the columns of Goll and Burdach

In the embryo up to the fifth month there is little difference in the appearance of the grey and white matter of the cord, but at that time the fibres in the columns of Burdach acquire their medullary sheaths or white substance of Schwann, the fatty matter of which is probably abstracted from the blood Very soon after these the basis bundles myelenate and then, in the sixth month, the columns of Goll Next follow the direct cerebellar

FIG 5.—SCHEMATIC REPRESENTATION OF TRANSVERSE SECTION THROUGH EARLY NEURAL TUBE (YOUNG), SHOWING AN EARLIER STAGE ON THE LEFT SIDE THAN ON THE RIGHT

tracts and, in the latter half of the eighth month the tracts of Gowers, while the fibres of the pyramidal and Lissauer's tracts do not gain their medullary sheaths until just before or after birth At first the spinal cord extends as far as the last mesodermal somite, but neuroblasts are only formed as far as the first coccygeal somite, so that behind that the cord is non-nervous and degenerates later into the filum terminale After the fourth month the nervous portion grows more slowly than the rest of the body

and so the long cauda equina and filum terminale are produced. At birth the lower limit of the cord is opposite the third lumbar vertebra, but in post-natal development it recedes still farther to the lower level of the first.

For further details *see* standard text books, *e.g.*, Quain's *Anatomy* and J. P. McMurrich, *Development of the Human Body* (1906).

Comparative Anatomy.—In the Amphioxus there is little difference between spinal cord and brain; the former reaches the whole length of the body and is of uniform calibre. It encloses a central canal from which a dorsal fissure extends to the surface of the cord and it is composed of nerve fibres and nerve cells; most of the latter being grouped round the central canal or neurocoele, as they are in the human embryo. Some very large multipolar ganglion cells are present, and there are also large fibres known as *giant fibres*, the function of which is not clear.

When the reptiles are reached the cord shows slight enlargements in the regions of the limbs and these become more marked in birds and mammals.

In the lumbar region of birds the dorsal columns diverge and open up the central canal, converting it into a diamond-shaped space which is only roofed over by the membranes of the cord, and is known as the *sinus rhomboidalis*.

In all these lower vertebrates except the Anura (frogs and toads), the cord fills the whole length of the spinal canal, but in the higher mammals (Primates, Chiroptera and Insectivora) it grows less rapidly, and so the posterior part of the canal contains the cauda equina within its sheath of dura mater. In mammals below the anthropoid apes there are no direct pyramidal tracts in the cord, since the decussation of the pyramids in the medulla is complete. Moreover, the crossed tracts vary very much in their proportional size to the rest of the cord in different animals. In man, for example, they form 11·87% of the total cross area of the cord, in the cat 7·76%, in the rabbit 5·3%, in the guinea-pig 3%, and in the mouse 1·14%. In the frog no pyramidal tract is found. It is obvious, therefore, that in the lower vertebrates the motor fibres of the cord are not so completely gathered into definite tracts as they are in man.

A good deal of interest has lately been taken in a nerve bundle which in the lower vertebrates runs through the centre of the central canal of the cord, and takes its origin in the optic reflex cells in close relation to the posterior commissure of the brain. More posteriorly (caudad) it probably acquires a connection with the motor cells of the cord and is looked upon as a means by which the muscles can be made to respond to the stimulus of light. It is known as *Reissner's fibre*, and its morphology and physiology have been studied most carefully in cyclostomes and fishes. It is said to be present in the mouse, but hitherto no trace of it has been found in man. It was discovered in 1860, but for forty years was looked upon as an artifact.

PHYSIOLOGY

The spinal cord is but a part of the nervous organ which throughout the length of the body forms the meeting-place of the nerve-paths arriving from and issuing to all regions with which nerve fibres communicate. To gain a true point of view for understanding the working of the spinal cord one must refer to the general function of the nervous system in the bodily economy.

Relation to General Nervous System.—An animal of microscopic size may continue throughout its life to be constituted entirely by one single cell. Animals of larger bulk, although each begins its existence as a single cell, attain their development by the multiplication of the original single cell, so that from it there comes to be formed a coherent mass of cells very many millions in number. In these multicellular animals each of the constituent cells is a minute self-centred organism, individually born, leading its own life and destined for individual death. The corporate power of the complex animal is the sum of the powers of those manifold individual existences, its cells. Of the agencies which integrate the complex animal, one of the most potent is nervous action. A certain number of the unit cells composing the animal are specially differentiated from the rest to bind the whole together by nervous action. These specially differentiated cells are called "neurones." They constitute living threads along which waves of physico-chemical disturbance are transmitted to act as releasing forces for the energy in distant cells.

It is characteristic of this nervous system, the system of neurones, that, although ramifying far and wide through the body, it is a continuum from end to end. The peripheral nerves are formed of bundles of neurones lying side by side, but these, although packed close together, are strictly isolated one from another as conductors and remain isolated throughout the whole length of the nerve. The points of functional nexus of the neurones one with another are confined to one region only of the whole system. All their conductive connections one with another take place solely in the central nervous mass which constitute the so-called central nervous system, a nervous organ extending axially along the length of the body midway between the body's lateral halves. Thither the neurones converge in vast numbers, those of each body segment converging to that fraction of the central organ which belongs to their body segment. The central nervous organ thus receiving these neurones is, where it lies in the head, called the brain, the rest of it is called in vertebrates the "spinal cord," in worms and arthropods the "nerve-cord." The central organ not only receives neurones which converge to it from outside, but many of its own neurones thrust out their conductive arms from it as nerve fibres carrying nervous influence outwards to regulate the activity of glands and muscles. In the vertebrates the ingoing neurones for each segment and similarly the outgoing neurone fibres are collected into a segmental nerve. To the spinal cord these are each attached by two roots, one dorsal, consisting of the afferent fibres, the other ventral, consisting of the efferent fibres.

The Reflex.—The simplest complete reaction of the system is a reflex. There are many reflexes which are extremely complex, being built up of a number of simpler reflexes combined. A reflex is a reaction started by the environment acting as a stimulus upon some nerve which communicates the excitement to other nerves by connections with them in the central nervous organ. The excitement so generated and transmitted finally travels outward from the central organ by one or more of the efferent nerves and through these reaches muscles or glands producing in them its final effect. The muscles and glands are from this point of view termed effector organs. The reaction is therefore "reflected" from the central organ. The nerve structures which include its trajectory are spoken of as a nervous arc. The whole purpose of the central nervous organ is to bring afferent neurones into touch with efferent neurones. The whole purpose of reflex arcs is to bind one part of the organism to another part in such a way that what the environment is doing to the organism at one place may appropriately call forth or restrain movement or secretion in the muscles or glands wherever situated in the organism.

Receptor Cells.—There is one condition for the due performance of these reactions which is not provided by the nervous system itself. The afferent neurones are not in most cases so constituted as to be excitable themselves directly by the environment—for instance, they cannot be stimulated by light. Their amenability to the environment, their sensitization to environmental agencies, is effected by special cells adjunct to their peripheral ends. These cells form organs called *receptors*. They are delicately adapted to be stimulated by this or that particular agent and are classifiable into various species, so that each species is easily excited by a particular agent which is "adequate" for it, and is inexcitable or excitable only with difficulty by agencies of other kinds. Thus in the skin some receptors are adapted for mechanical stimuli (touch) and not for thermal stimuli, while others (cold spots, warm spots) are adapted for thermal stimuli and not for mechanical. As far as it is known each afferent neurone is connected with receptors of one species only. The receptors thus confer upon the reflex arcs selective excitability.

Each arc is thus tuned to respond to certain stimuli, while other arcs not having that kind of receptor do not respond The receptors, therefore, while increasing the responsiveness of the organism to the environment, prevent confusion of reactions (incoordination) by limiting to particular stimuli a particular reaction

Proprioceptors.—The system of neurones is thus made accessible to the play of the external world acting on the body And in addition to those receptors which are stimulated directly by the external world, are others lying within the mass of the organism itself, which are excitable by actions occurring in the organism itself These are called *proprioceptors* They are distributed preponderantly in the muscles and structures functionally adjunct to muscle, such as joints, ligaments, fasciae, etc The reactions both passive and active induced in such motor structures, reflexly by environmental stimuli, tend therefore secondarily to be followed and accompanied by reflex reactions initiated from proprioceptors

Conduction.—The process by which the excitement generated in the afferent neurone travels along the reflex arc is known as *conduction* Conduction along afferent and efferent nerves differs in some important respects from that obtaining in the nerve centre, *i e*, in the piece of the central nervous system connecting the afferent nerve with the efferent nerve In a nerve-trunk the excited state set up in it by a stimulus travels along its fibres as wave-like disturbance at a speed of about 100 metres per second, and does not alter in intensity or speed in its travel A nerve-trunk when excited at some point along its length transmits the "impulse," *i e*, the wave-like excited state in both directions, *i e*, both up and down each fibre, from the point stimulated This is true whether the fibre is afferent or efferent The speed of travel of the nervous impulse along the nerve-trunk is the same whether the nervous impulse is weak or intense The nerve-trunk shows practically no delay in its response to an effective, even though weak, stimulus and its response ceases practically at once on cessation of the exciting stimulus. When excited by repeated brief stimuli the rhythm of the response corresponds closely with that of the stimuli, even when the frequency of the latter is as high as 500 per second With momentary stimuli a response even so brief as 20 can be given by the nerve-trunk Finally, nerve-trunk conduction is singularly resistant to fatigue, to impoverished blood supply, and to many drugs which powerfully affect reflex actions

Through the central nervous organ the travel of the impulse exhibits departure from these features. Its intensity is liable to be altered in transit Its time of transit is much longer than for a similar length of nerve-trunk Its direction of transmission becomes polarized, that is, confined to one direction along the nervous path To a strong stimulus the central reaction instead of being as brief as an impulse, may endure for a whole second or more. A stimulus not capable of evoking a response from a centre when applied once may by simple repetition become effective (*temporal summation*). It is in the *grey matter* that conduction differs in these respects from conduction in nerve-trunks In the grey matter each afferent fibre breaks up into branching threadlets which ramify in various directions and terminate in close apposition with other neurones. The point of nexus of one neurone with another is termed the *synapse* If synapsis occurs by contiguity and not homogeneous continuity, it is fair to suppose that at it the transmission of nervous impulses must be different from that observable in the homogeneous conducting threads of nerve fibres. The conduction must traverse something of the nature of a membrane

Reflex Reactions.—When the spinal cord is severed at any point the reflex arcs of the portion of the body behind the transection are quite cut off from the rest of the nervous system in front, including the brain The reflex reactions elicited from the thus isolated region cannot therefore be modified by the action of the higher nervous centres In the head the local centres are overlaid by higher centres which cannot by any simple severance be separated from them. By studying, therefore, the powers of the cord behind a complete spinal transection we can obtain information as to the powers of the purely local or segmental reflex mechanisms.

The so-called "flexion-reflex" of the limb is one of the most accessible of the local reflex reactions which can thus be studied with an isolated portion of the spinal cord as its centre

Let it be supposed that the limb observed is the hind limb The three main joints of the limb are the hip, the knee and the ankle Each of these joints is provided with muscles which flex or bend it, and others which extend or straighten it It is found that the reflex throws into contraction the flexor muscles of each of these joints It matters little which of all the various afferent nerves of the limb is stimulated, whichever of these the afferent nerve may be, the centrifugal discharge goes to practically the same muscles, namely, always to the flexors of the joints

Not only does the reflex action not discharge motor impulses into the nerves of the extensor muscles, but if the spinal cord happens to be discharging impulses into these nerves when the reflex is evoked this discharge is suppressed or diminished (*inhibited*) In this way the latter muscles are prevented from impeding the action of the contracting flexors This inhibition prevents other reflexes from upsetting for the time being the due action of the flexion-reflex, for it renders the muscles opposing that reflex less accessible to motor discharge through the spinal cord whatever the quarter whence incitation to that discharge may come

A feature of this reflex is its graded intensity A weak stimulus evokes in the flexor muscles a contraction which is weak and in the extensor muscles a relaxation which is slight In the case of the muscle-fibre any strength of stimulus if sufficient to excite it at all excites the fibre totally and evokes its full contraction (Keith-Lucas) and this latter remains the same in amount so long as the mechanical and nutritive conditions of the fibre remain constant Each muscle-fibre reacting on this "all-or-none" principle and each nerve-fibre similarly responding on that same principle (Kato), different amounts of contraction yielded by the muscle under different strengths of stimulation of its nerve signify differences simply in the number of muscle-fibres which the stimulus excites In other words the weaker stimuli excite fewer of the nerve-fibres innervating the muscle When the tension developed by the muscle, *e g*, against a stiff spring, reaches the maximal obtainable from it, that fact tells us that all the muscle-fibres are then in contraction, when the tension development is less than maximal some of the muscle-fibres are not in action A stimulus to the nerve which evokes maximal tension from the muscle is one which succeeds in exciting all the nerve-fibres innervating the muscle, and any stimulus which evokes less than maximal tension is leaving some of the nerve-fibres "idle"

The tension developed by a muscle under reflex excitation falls short of its maximal tension, even when the afferent nerve is stimulated maximally The reflex activates a proportion only of the total aggregate of the muscle's fibres, and therefore a proportion only of the spinal motor neurones innervating the muscle But within the range of the limit imposed by the maximal number of muscle-fibres which it *can* activate, the grading of the number activated in accordance with the grading of the strength of stimulation of the afferent nerve is very delicate, much more so than in the case of the motor nerve itself The actual fractional proportion of the muscle's total aggregate of motor units which an afferent nerve, maximally stimulated, can activate, differs from one afferent nerve to another, and for the same afferent nerve in different experiments A subconvulsive dose of strychnine raises the size of the fraction The threshold value of stimulus for the reflex is usually higher than for the contraction of the muscle from the motor nerve. Spinal reflex action no more regards "muscles" than does a motor centre of the cerebral cortex Both ignore muscles as entities and have in view movements purely A weak flexion-reflex activates a few fibres of each of the several flexor muscles of the limb The reflex treats a complex composed from some (*i e*, those of similar threshold for the particular afferent nerve) motor-units of hip-flexor, of knee-flexor and of ankle-flexor as functionally more homogeneous than is the total group of fibres composing any one of these muscles alone

Reflex inhibition has its seat in the grey matter of the spinal centre It acts at some point in the reflex arc up-stream from

the all-or-none motor unit (motor nerve-fibre with its group of muscle-fibres). The inhibitory reflex is like the excitatory capable of very delicate grading; its effect in diminishing or precluding this or that amount of an excitatory reflex is effected entirely by regulating the number of the motor units thrown out of action or kept out of action. Intensity of contraction or of relaxation is thus in both cases a question simply of number of motor-units reacting. The reflex centre continues discharging impulses for a certain time after its exciting stimulus has ceased. This after-discharge succeeding a strong stimulus may persist even for several seconds.

Refractory Phase.—Besides characters common to all or many spinal reflexes certain spinal reflexes have features peculiar to themselves or exhibited by them in degrees not obvious in other reflexes. One of these features is refractory phase. The scratch-reflex exemplifies this. In the dog, cat and many other animals the hind limb often performs a rapid scratching movement, the foot being applied to the skin of the shoulder or neck as if to groom the hairy coat in that region. This movement is in the intact animal under control of the brain, and can be executed or desisted from at will. When certain of the higher centres in the brain have been destroyed, this scratching action occurs very readily and in an uncontrolled way. When the spinal cord has been severed in the neck this scratching movement of the hind limb can be elicited with regularity as a spinal reflex by merely rubbing the skin of the side of the neck or shoulder, or applying there a weak electric current to the skin. In this reflex the stimulus excites afferent nerves connected with the hairs in the skin and these convey impulses to the spinal centres in the neck or shoulder segments, and these in turn discharge impulses into nerve fibres entirely intraspinal passing backward along the cord to reach motor centres in the hind limb region. These motor centres in turn discharge centrifugal impulses into the muscles of the hind limb of the same side of the body as the shoulder which is the seat of irritation. The motor discharge is peculiar in that it causes the muscles of the hind limb to contract rhythmically at a rate of about four contractions per second, and the discharge is peculiar further in that it excites the flexor and extensor muscles of the joints alternately so that at the hip for instance the limb is alternately flexed and extended, each single phase of the movement lasting about an eighth of a second. Now this rhythmic discharge remains the same in rate whether the exciting stimulus applied to the skin be continuous or one of many various rates of repetition. Evidently at some point in the reflex arc there is a mechanism which after reacting to the impulses reaching it remains for a certain brief part of a second unresponsive, and then becomes once more for a brief period responsive, and so on. And this phasic alternation of excitability and inexcitability repeats itself throughout the continuance of the reflex. The phase of inexcitability is termed the *refractory* phase. Its seat lies in the spinal centre. A similar element almost certainly forms part of the co-ordinating mechanism for many other cyclic reflexes, including those of the stepping of the limbs, the movement of the jaw in mastication, the action of the eyelids in blinking, and perhaps the respiratory movements of the chest and larynx.

Fatigue.—Nerve trunks do not easily tire out under stimulation even most prolonged. Reflex actions on the other hand relatively soon tire. Some are more resistant, however, than are others. The flexion-reflex may be continued for ten minutes at a time. As a reflex tires, the muscular contraction which it causes tends to become less intense and less steady. The relatively rapid onset of fatigue in reflexes is counterbalanced by speedy recovery in repose. A long flexion-reflex, when from fatigue it has become weak, tremulous and irregular, will recommence after 30 seconds' repose with almost the same vigour and steadiness as if it had not recently been tired out.

The natural movements to which the artificially provoked reflexes seem to correspond do not demand prolonged motor activity, or when they do, demand it in rhythmic repetition with intervening pauses which allow repose.

Reflex Postures.—But there are certain reflexes which do persist for long periods at a time. These are reflex postures. The hind limbs of the "spinal" frog assume an attitude which is reflex, for it ceases on severance of the afferent spinal roots. This attitude is one of flexion at hip, knee and ankle, resembling the well-known natural posture of the frog as it squats when quiet in the tank. Similarly in the "decerebrate" dog or cat certain muscles, *e.g.*, the limb extensors, exhibit a persistent contraction. These tonic reflexes are related to attitudes. In the dog and cat they are exhibited by those muscles whose action antagonizes gravity in postures which are usual in the animal, thus the extensors of the knee and hip and shoulder and elbow are in tonic contraction during standing. The postural contraction is accompanied by electrical "action currents" like those of other contraction, though weak and indicative of self-smothering from the rhythms being asynchronous in the contributory fibre-groups. The postural contraction of the extensor muscles in the maintenance of the erect posture is traceable to a reflex, called the *stretch-reflex.* A stretch, *e.g.*, by a pull upon the tendon, lengthening the muscle by even so little as $\frac{1}{2}\%$, excites reflex contraction of some of its fibres. The passive stretch is a mechanical stimulus to some of the proprioceptive organs (perhaps the muscle-spindles) in the muscle. The reflex is therefore unobtainable when the afferent nerve-fibres of the muscle itself have been severed. The essential centre for the stretch-reflex is spinal, but mid-brain and cerebellar centres much reinforce it. In the erect posture the head, neck, tail and jaw would droop and the limbs fold up under their own weight and that of superincumbent parts, were not the "antigravity" muscles checked from yielding by the stretch-reflex which their own passive yield induces in themselves. Hence the reflexly maintained "standing" is a multiple stretch-reflex. Considerable latitude of actual pose is allowed to the individual parts because each muscle involved acts for itself and develops and regulates its own stretch-reflex.

Characteristic of reflex postural contraction is its continuance for long spells at a time without obvious fatigue. Attempts are uniformly unsuccessful to reproduce this feature by electrical stimulation of afferent nerves or of the muscle's motor nerve. The suggestion has therefore been made that the postural contraction of muscle is due to a different process in the muscle-fibre from that of the ordinary contraction executing movements and so easily and often studied under electrical stimulation in the laboratory. Forbes, however, has offered the satisfactory explanation that the postural contraction while the same process as that of ordinary reflex and other contraction involves usually relatively few motor units at a time and these as they fatigue, are replaced by others. The stretch which is the essential stimulus is automatically shifted to fresh motor-units so soon as those already in operation begin to yield and give out. Grafted, as it were, upon the reflex maintenance of the erect-posture are reflexes of locomotion which are also certainly spinal in essence, and essentially proprioceptive. The hind-limbs of the dog, after severance of the cord in the thoracic region, begin to step when released from the ground. Their stepping will go on sometimes quicker and sometimes slower for long periods at a time. Kinematograph analysis of this spinal stepping shows that it is identical with normal stepping except for a slight flexional yield when the limb is vertically on the ground in the normal step. Passively supported mid-flexion of knee and hip even of one hind limb alone at once causes the spinal reflex stepping to cease, in both limbs usually. The proprioceptive stimulus of the spinal stepping may therefore be the passive stretching of the hip and knee-flexor. From observations on stepping under narcosis Graham Brown regards the essential factor in "spinal" stepping to be the intrinsic activity of a "spinal stepping" centre or "centres." Certainly it is not uncommon for an extensor muscle of the limb in isolated attachment to the myograph and after its own afferent nerve fibres have been wholly destroyed and after all the other muscles of the limb have been put out of play by excision of nerve-section to start stepping on its own accord in the bulbospinal preparation. Skin stimuli, for instance, the contact of the sole with the ground, are not necessary for the reflex stepping. On the other hand the ground pressure against the toe pads and plantar cushion seems an important factor in the gallop—indeed the sudden brief

though strong and almost simultaneous extension of all four limbs in the gallop can in the spinal animal be evoked by pressure simulating the ground pressure, and when applied even to one hind foot only.

The eyeballs are eminently organs which, the gaze being a posture, employ active postures throughout the waking day The proprioception of the neck-muscles excites from the cervical spinal cord reflex influences acting on the nerves of the eyeball muscles. An instance is: turning of the neck toward one side excites turning of the eyeballs toward the opposite side. Or again, a clockwise partial rotation of the neck round its long axis excites from the neck proprioceptor a compensatory anti-clockwise rotation of the eyeballs These reflex postures of the eyeballs are sometimes called compensatory, because they tend to keep truly vertical the vertical of the retina despite displacements of the head by the movements of the neck.

It may be mentioned here that the spinal and the bulbospinal animal (cat) although its composite stretch-reflex enables it when placed in the erect posture to maintain that attitude, even for hours at a time, is yet not capable of assuming that posture when laid, for instance, on its side. But when the mid-brain is retained in addition to hind-brain and cord the animal has that power of righting itself. These righting reflexes are likewise postural and largely evoked by the otolith organs Although not truly spinal reflexes their field of nervous operation overruns into the spinal cord.

The Spinal Reflex Arcs of the Hind Limb.—When the skin of the limb is stimulated the flexion-reflex already described is evoked. The reflex is excited by nocuous stimuli such as a prick or squeeze applied to the skin anywhere in the limb, but most easily when applied to the foot The reflex flexion of the ipsilateral hind limb is commonly accompanied by reflex extension of the opposite hind limb.

In the dog and cat extension of the ipsilateral hind limb can, however, be excited by stimulation of the skin in three limited regions One of these is the sole of the foot; smooth pressure between the pads excites a strong brief extension This is called the extensor thrust It is accompanied by a similar sudden brief extension of all three other limbs. This reflex may be related to the action of galloping, and the pressure which excites resembles that which the weight of the body bears on the pads against the ground

The two other regions are the skin of the front of the groin supplied by the crural branch of the genito-crural nerve, and the skin just below and mesial to the buttock These always excite the extensor muscles, not the flexors They may be concerned with sexual acts

Reflexes of the Fore Limb.—The ipsilateral reflex is flexion at shoulder, elbow and wrist The contralateral fore limb at the same time is extended at shoulder, elbow and wrist

The Scratch Reflex.—The area from which it can be excited extends from the ear to the loin Each of these reflexes is a co-ordinate reaction. It is seen, therefore, that through the medium of the spinal cord the body behind the head has at command a certain number of reflexes and that each of these manages the skeletal musculature in a co-ordinate way The muscles worked by these several reflexes are to a large extent common to them all Some resemble one another in regard to their action upon a particular muscle. Some act in opposite ways upon a particular muscle. In order to follow the co-ordination effected by the spinal cord we have to turn to a certain feature in the scheme of construction of the nervous system This feature embodies what is termed the *principle of the common path.*

Interaction Between Reflexes.—At the commencement of every reflex-arc is a receptive neurone extending from the receptive surface to the central nervous organ This neurone forms the sole avenue which impulses generated at its receptive point can use whithersoever be their destination. This neurone is therefore a path exclusive to the impulses generated at its own receptive point, and other receptive points than its own cannot employ it. A single receptive point may play reflexly upon quite a number of different effector organs It may be connected through its reflex path with many muscles and glands in many different regions Yet all its reflex arcs spring from the one single shank or stem, *i.e.*, from the one afferent neurone which conducts from the receptive point at the periphery into the central nervous organ.

But at the termination of every reflex arc we find a final neurone, the ultimate conductive link to an effector organ (muscle or gland) This last link in the chain, *e g*, the motor neurone, differs obviously in one important respect from the first link of the chain It does not subserve exclusively impulses generated at one single receptive source, but receives impulses from many receptive sources situate in many and various regions of the body It is the *sole* path which all impulses, no matter whence they come, must travel if they are to act on the muscle fibres to which it leads

Therefore, while the receptive neurone forms a private path exclusively serving impulses of one source only, the final or efferent neurone is, so to say, a public path *common* to impulses arising at any of many sources of reception. A receptive field, *e g.*, an area of skin, is analysable into receptive points. One and the same effector organ stands in reflex connection not only with many individual points, but even with many various receptive *fields* Reflexes generated in manifold sense-organs can pour their influence into one and the same muscle Thus a limb muscle is the *terminus ad quem* of many reflex arcs arising in many various parts of the body Its motor nerve is a path common to all the reflex arcs which reach that muscle

Reflex arcs show, therefore, the general features that the initial neurone of each is a *private* path exclusively belonging to a single receptive point (or small group of points), and that finally the arcs embouch into a path leading to an effector organ; and that their final path is common to all receptive points wheresoever they may lie in the body, so long as they have connection with the effector organ in question Before finally converging upon the motor neurone the arcs converge to some degree Their private paths embouch upon *internuncial* paths common in various degrees to groups of private paths The terminal path may, to distinguish it from internuncial common paths, be called *the final common path.* The motor nerve to a muscle is a collection of final common paths

Certain consequences result from this arrangement One of these is the preclusion of essential qualitative difference between nerve-impulses arising in different afferent nerves If two conductors have a tract in common there can hardly be essential qualitative difference between their modes of conduction.

A second consequence is that each receptor being dependent for final communication with its effector organ upon a path not exclusively its own but common to it with certain other receptors, such nexus necessitates successive and not simultaneous use of the common path by various receptors using it to *different or opposed* effect.

In the simultaneous correlation of reflexes some reflexes combine harmoniously, being reactions that mutually reinforce. These may be termed *allied reflexes,* and the neutral arcs which they employ *allied arcs.* On the other hand, some reflexes, as mentioned above, are *antagonistic* one to another and incompatible These do not mutually reinforce, but stand to each other in inhibitory relation One of them inhibits the other

Allied Reflexes.—What happens when trains of impulses, travelling by convergent afferent arcs, meet at the same "common path?" With convergent reflexes which are "allied" in the above sense, this case must be one of extremely frequent occurrence and the management of the interaction between the convergent streams of impulses must be a fundamental factor in nervous co-ordination. The afferent path A embouches upon the intraspinal motor neurones of the knee-flexor and can activate 75% of them The afferent path B embouches also upon the motor neurones of the same muscle and can activate 75% of them When the muscle is reflexly contracting to A with a tension 75% of that of the muscle's maximal contraction, stimulation of B is added The contraction tension in result rises to 85% of the maximal The inference is that for 65% of the total motor units

of the muscle the excitation from A acts upon the same motor units as would that from B. In other words 65% of the total aggregate of the motor units of the muscle are common to A and to B. The stream of impulses arriving at these common motor-units from B when A's stream is already activating them leaves their activity unchanged, failing either to increase or to diminish it. A's stream, which is engaging them, precludes B's stream from engaging them. This is termed *occlusion.* We may turn from the case of the group to that of the single individual unit. Suppose a to be a train of impulses reaching a central terminal of path A and impinging upon a motor-unit μ and activating it. Suppose β similarly a train impinging by one of path B's terminals upon the same motor unit μ already activated by a. It has been argued that the resultant response of μ to the double series of impulses impinging on it will show interference and interruption and unsteadiness from "inhibition," the impulses generated by the one train interfering with those generated by the other owing to the refractory phase following in the wake of each impulse. Experiment fails to substantiate such unsteadiness or other evidence of "interference inhibition" even when the impulse trains are each of them at 180 p. sec. Experiment in fact finds the reverse; the resultant contraction being steadier and more durable under the concurrent excitation of A and B than under either alone. An important kind of observation is the following, since it shows clearly that, against the interference view above, "occlusion" is not inhibition. An afferent A activates 50% of a given muscle's motor units. An afferent B activates a still larger percentage of the muscle's motor units. When afferent B is already activating the muscle the stimulation of A causes no outward result on the muscle, but if B's stimulus be then withdrawn A's continuing, the contraction at once falls to and remains at 50% of maximal. A's activation was occluded by B's already existent one, but there was no inhibition. A's activation was occluded throughout the large field amounting to 50% of the total aggregate of the motor units. Yet that not a single motor unit was inhibited, has been experimentally established by taking for B one of the relatively rare afferents which activate 100% of the muscle. Since B is then activating every motor unit it cannot be supposed that lack of A's effect when A is concurrently stimulated is due to inhibition of A's 50% of the motor units; for that would suppose those motor units to be at one and the same time both active and inhibited. The mutual support that the two trains yield each other in the actually observed result argues the immediate replacement of B's effect by A's when B's lapses or intermits; and *vice versa.* That this would be so is borne out by other observations. Where, during the concurrence of A and B, A's effect has been occluding B from activating, on abruptly ceasing to stimulate A, so that B remains under stimulation alone, B which has till then been ineffective owing to occlusion, at once appears as effective and without hesitation or pause replaces that of A step for step as A's after-discharge subsides. The final common path under this competition of allied arcs is comparable with a telephone line already "busy" for one subscriber and for that time "engaged" and non-available to other subscribers. The action of the principle of the final common path may be instanced in regard to "allied arcs" in the scratch-reflex as follows. If, while the scratch-reflex is being elicited from a skin point at the shoulder, a second point distant 10mm. from the other point but also in the receptive field of skin, be stimulated, the stimulation at this second point favours the reaction from the first point. This is well seen when the stimulus at each point is of subminimal intensity. The two stimuli, though each unable separately to invoke the reflex, yet do so when applied both at the same time. The "receptive field" of a reflex is really the common area of commencement of a number of allied arcs.

Antagonistic Reflexes.—But not all reflexes connected to one and the same common final path stand to one another in the relation of "allied reflexes." Suppose during the scratch-reflex a stimulus be applied to the foot not of the scratching side, but of the opposite side. The left leg, which is executing the scratch-reflex in response to stimulation of the *left* shoulder skin is cut short in its movement by the stimulation of the *right* foot, although the stimulus at the shoulder to provoke the scratch movement is maintained unaltered all the time. The stimulus to the right foot will temporarily interrupt a scratch-reflex, or will cut it short or will delay its onset; which it does of these depends on the time-relations of the stimuli. The inhibition of the scratch-reflex occurs sometimes when the contraction of the muscles innervated by the reflex conflicting with it is very slight. There is interference between the two reflexes and the one is inhibited by the other.

The reflex from the right foot evokes at the opposite (left) knee extension; in doing this it causes steady excitation of extensor neurones of that knee and steadily inhibits the flexor neurones. But the scratch-reflex causes rhythmic excitation of the flexor neurones. Therefore these flexor neurones in this conflict lie as a final common path under the influence of two antagonistic reflexes, one of which would excite them to rhythmical discharge four times a second, while the other would continually repress all discharge in them.

In all these forms of interference there is a competition, as it were, between the excitatory stimulus used for the one reflex and the excitatory stimulus for the other. Both stimuli are in progress together, and the one in taking effect precludes the other's taking effect as far as the final common path is concerned.

Again, if, while stimulation of the skin of the shoulder is evoking the scratch-reflex, the skin of the hind foot of the *same* side is stimulated, the scratching may be arrested. Stimulation of the skin of the hind foot by any of various stimuli that have the character of threatening the part with damage causes the leg to be flexed, drawing the foot up by steady maintained contraction of the flexors of the ankle, knee and hip. Here, therefore, there is an arc which embouches into a final path, common to it and to the scratch-reflex arc; both these arcs employ the same effector organ, namely, the knee-flexor, and employ it by the common medium of the final path FC. But though the channels for both reflexes embouch upon the same final common path, the excitatory flexor effect specific to each differs strikingly in the two cases. In the scratch-reflex the flexor effect is an intermittent effect; in the noci-ceptive flexion-reflex the flexor effect is steady and maintained. The scratch-reflex is set aside by that of the noci-ceptive arc from the homonymous foot.

The stimulation which previously sufficed to provoke the scratch-reflex is no longer effective, though it is continued all the time. But when the stimulation of the foot is discontinued the scratch-reflex returns. In that respect, although there is no enforced inactivity, there is an *interference* which is tantamount to, if not the same thing as, inhibition. Though there is no cessation of activity in the motor neurone one form of activity that was being impressed upon it is cut short and another takes its place. A stimulation of the foot too weak to cause more than a minimal reflex will often completely suffice to interrupt, or cut short, or prevent onset of, the scratch-reflex.

The kernel of the interference between the homonymous flexion-reflex and the scratch-reflex is that both employ the same final common path FC to different effect—just as in the interference between the crossed extension-reflex and the scratch-reflex. Evidently, the homonymous flexion-reflex and the crossed extension-reflex both use the same final common path FC. And they *use it to different effect.* The motor neurone to the flexor of the knee being taken as a representative of the final common path, the homonymous flexion-reflex inhibits it from discharging. Hence if, while the direct flexion-reflex is in progress, the crossed foot is stimulated, the reflex of the knee-flexor is inhibited. The crossed extension reflex therefore inhibits not only the scratch-reflex, but also the homonymous flexion-reflex.

Further, in all these interferences between reflexes the direction taken by the inhibition is reversible. Thus, the scratch-reflex is not only liable to be inhibited by, but is itself able to inhibit either the homonymous flexion-reflex or the crossed extension-reflex; the homonymous flexion-reflex is not only capable of being inhibited by the crossed extension-reflex, but conversely in its turn can inhibit the crossed extension-reflex. These interferences are therefore reversible in direction. Certain conditions

determine which reflex among two or more competing ones shall obtain mastery over the final common path and thus obtain expression

As to the intimate nature of the mechanism which thus, by summation or by interference, gives co-ordination where neurones converge upon a common path, it is difficult to surmise. In the central nervous system of vertebrates, afferent neurones A and B in their convergence toward and impingement upon another neurone Z, towards which they conduct, do not make any lateral connection directly one with the other—at least, there seems no clear evidence that they do It seems, then, that the only structural link between A and B is neurone Z itself. Z itself should therefore be the field of coalition of A and B if they transmit "allied" reflexes.

Factors Determining the Sequence.—The formation of a common path from tributary converging afferent arcs is important because it gives a co-ordinate mechanism. There the dominant action of one afferent arc, or set of allied arcs in condominium, is subject to supersession by another afferent arc, or set of allied arcs, and the supersession normally occurs without intercurrent confusion

Whatever be the nature of the physiological process occurring between the competing reflexes for dominance over the common path, the issue of their competition, namely, the determination of which one of the competing arcs shall for the time being reign over the common path, is largely conditioned by four factors These are spinal induction, relative fatigue, relative intensity of stimulus, and the functional species of the reflex

1 Induction occurs in two forms, one of which has been named *immediate induction* The stimulus which excites a reflex tends by central spread to facilitate and lower the threshold for reflexes allied to that which it particularly excites A constellation of reflexes thus tends to be formed which reinforce each other, so that a reflex figure results If the prepotent stimulus shifts, allied arcs are by the induction particularly prepared to be responsive to it or to a similar stimulus.

Immediate induction only occurs between allied reflexes Its tendency in the competition between afferent arcs is to fortify the reflex just established, or, if transition occur, to favour transition to an allied reflex Immediate induction seems to obtain with highest intensity at the outset of a reflex, or at least near its commencement

The other form of spinal induction is *successive induction* It is in several ways the reverse of the preceding If the crossed-extension reflex of the limb of the "spinal" dog be elicited at regular intervals, say once a minute, by a carefully adjusted electrical stimulus of defined duration and intensity, the resulting reflex movements are repeated each time with much constancy of character, amplitude and duration If in one of the intervals a strong prolonged (*e g*, 30″) flexion-reflex is reduced from the limb yielding the extensor-reflex movement, the latter reflex is found intensified after the intercurrent flexion-reflex. The intercalated flexion-reflex lowers the threshold for the aftercoming extension-reflexes, and especially increases their after-discharge This effect may endure, progressively diminishing, through four or five minutes, as tested by the extensor reflexes at successive intervals. Now, as we have seen, *during* the flexion-reflex the extensor arcs were inhibited: *after* the flexion-reflex these arcs are in this case evidently in a phase of exalted excitability The phenomenon presents obvious analogy to visual contrast. The exaltation after-effect may ensue with such intensity that simple discontinuance of the stimulus maintaining one reflex is immediately followed by "spontaneous" appearance of the antagonistic reflex

The so-called "mark-time" reflex of the "spinal" dog is an alternating stepping movement of the hind limbs which occurs on holding the animal up so that its limbs hang pendent. It can be inhibited by stimulating the skin of the tail. On cessation of that stimulus the stepping movement sets in more vigorously and at quicker rate than before This after-increase might be explicable in either of two ways It might be due to the mere repose of the reflex centre, the repose so recruiting the centre as to strengthen its subsequent action. But a similar period of repose obtained by simply supporting one limb—which causes cessation of the reflex in both limbs, the stimulus being stretch of the hip-flexors under gravity—is not followed by after-increase of the reflex, or the after-increase might result from the inhibition being followed by a rebound to super-activity This latter seems to be the case The after-increase occurs even when both hind limbs are passively lifted from below during the whole duration of the inhibitory stimulus applied to the tail And the reflex inhibition of the knee-extensor by stimulation of the central end of its own nerve is followed by marked rebound to superactivity of the extensor itself Again, the knee jerk, after being inhibited by stimulation of the hamstring nerve, is more brisk than before the inhibition

By virtue of this spinal contrast, therefore, the extension-reflex predisposes to and may actually induce a flexion-reflex, and conversely the flexion-reflex predisposes to and may actually induce an extension-reflex This process is qualified to play a part in linking reflexes together in alternating sequence

Much of the reflex action of the limb that can be studied in the "spinal" dog bears the character of locomotion This has been shown recently with particular clearness by the observations of Phillipson. In the stepping of the limb the flexion that raises the foot and carries it clear of the ground prepares the antagonistic arcs of extension, and, so to say, sensitizes them to respond later in their turn by the supporting and propulsive extension of the limb necessary for progression The reflex "stepping" of the "spinal" dog proceeds without an *external* skin stimulus: it will continue when the dog is held in the air The cat walks well when all four feet are anaesthetized

A reflex movement must generate in its progress a number of further stimuli and throw up a shower of centripetal impulses from the moving muscles and joints into the spinal cord Squeezing of muscles and stimulation of their afferent nerves and those of joints, etc, elicit reflexes The primary reflex movement might be expected, therefore, of itself to initiate further reflex movement, and that secondarily to initiate further still, and so on Yet on cessation of the external stimulus to the foot in the flexion-reflex the whole reflex comes usually at once to an end The scratch-reflex, even when violently provoked, ceases usually within two seconds of the discontinuance of the external stimulus that provoked it We have as yet no satisfactory explanation of this

2 Another condition influencing the issue of competition between reflexes of different sources for possession of one and the same final common path is fatigue A spinal reflex under continuous excitation or frequent repetition becomes weaker, and may cease altogether This decline is progressive, and takes place earlier in some kinds of reflexes than it does in others In the "spinal" dog the scratch-reflex under ordinary circumstances tires much more rapidly than does the flexion-reflex

A reflex as it tires shows other changes besides decline in amplitude of contraction. Thus in the flexion-reflex, the original steadiness of the contraction decreases, it becomes tremulous, and the tremor becomes progressively more marked and more irregular Finally, an irregular phasic tremor of the muscles is all that remains It is not the flexor muscles themselves which tire out, for these, when under fatigue of the flexion-reflex contract no longer for that reflex, contract in response to the scratch-reflex which also employs them.

Similar results are furnished by the scratch-reflex, with certain differences in accord with the peculiar character of its individual charge. One of these latter is the feature that the individual beats of the scratch-reflex usually become slower and follow each other at slower frequency. Also the beats, instead of remaining fairly regular in amplitude and frequency, tend to succeed in somewhat regular groups The beats may disappear altogether for a short time, and then for a short time reappear

When the scratch-reflex elicited from a spot of skin is fatigued, the fatigue holds for that spot, but does not implicate the reflex as obtained from the surrounding skin The reflex is, when tired out to stimuli at that spot, easily obtainable by stimulation two or

more centimetres away.

The local fatigue of a spinal reflex seems to be recovered from with remarkable speed. A few seconds' remission of the stimulus suffices for marked though incomplete restoration of the reaction. Fatigue seems a process elaborated and preserved in the selective evolution of the neural machinery. One obvious use attaching to it is the prevention of the too prolonged continuous use of a common path by any one receptor. It precludes one receptor from occupying for long periods an effector organ to the exclusion of all other receptors. It prevents long continuous possession of a common path by any one reflex of considerable intensity. It favours the receptors taking turn about. It helps to ensure serial variety of reaction. The organism, to be successful in a million-sided environment, must in its reaction be many sided. Were it not for such so-called fatigue, an organism might, in regard to its receptivity, develop an eye, or an ear, or a mouth, or a hand or leg, but it would hardly develop the marvellous congeries of all those various sense-organs which it is actually found to possess.

The final efferent-root neurone forms the instrument for many different reflex arcs and acts. It is responsive to them in various rhythms and in various grades of intensity. In accordance with this, it seems from experimental evidence to be *relatively indefatigable.*
